Institution of Civil Engineers (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. R. A. Foulkes: "The Use of Light Alloys in Structures".

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. G. Pearce: "Recent Developments in Cast Iron".

Manchester Geographical Society (at the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Miss F. A. Roper: "Places of Interest on the Mediterranean Seaboard".

Royal Statistical Society, Tees-side Sub-group of the Industrial Applications Section (at the William Newton School, Norton, Stockton-on-Tees), at 7 p.m.—Dr. O. L. Davies: "Correlation Problems in the Chemical Industry".

Tuesday, April 6—Friday, April 9

Physical Society (at Imperial College, Imperial Institute Road, London, S.W.7).—Thirty-second Exhibition of Scientific Instruments and Apparatus.

Wednesday, April 7

Institute of Fuel, North-Western Section (at the Engineers' Club, Albert Square, Manchester), at 1.30 p.m.—Annual General Meeting; at 2.30 p.m.—Dr. H. E. Crossley: "External Deposits on the Heating Surface of Boiler Plant".

Royal Society of Medicine, History of Medicine Section (at 1 Wimpole Street, London, W.1), at 2.30 p.m.—Symposium on "Conan Doyle and the Doctor and Detective Fiction".

Royal Statistical Society, Birmingham Group of the Industrial Applications Section (at the Chamber of Commerce, 95 New Street, Birmingham), at 6.30 p.m.—Dr. D. G. Beech: "Statistics Applied to Pottery Problems".

Institute of Welding, Manchester and District Branch (in the Reynolds Hall, College of Technology, Manchester), at 7 p.m.—Annual General Meeting; Mr. G. Foster: "Welding in Railway Workshops".

Society of Public Analysts and other Analytical Chemists (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Scientific Papers.

Thursday, April 8

Physical Society, Acoustics Group (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 5.15 p.m.—Annual General Meeting; at 5.45 p.m.—Discussion on "The Use of Microphones and Loudspeakers in Buildings and Sound Amplification and Distribution" (to be opened by Mr. Hope Bagenal).

Institute of Physics, Electron Microscopy Group (in the Anatomy Lecture Theatre, King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. V. E. Cosslett: "Recent Advances in Electron Microscopy in Great Britain".*

British Institution of Radio Engineers, London Section (at the E.M.I. Studios, Ltd., Abbey Road, London, N.W.8), at 6 p.m.—Mr. W. S. Barrell and Dr. G. F. Dutton: "High Fidelity Recording and Reproduction".

Chemical Society (in the Chemistry Department, The University, Manchester), at 6.30 p.m.—Scientific Papers.

British Institution of Radio Engineers, North-Western Section (in the Reynolds Hall, College of Technology, Sackville Street, Manchester), at 6.45 p.m.—Mr. H. Stibbe and Mr. K. G. Lockyer: "Factors Governing the Performance of I.F. Amplifiers".

Friday, April 9

Biochemical Society (at University College, Dublin), at 1.30 p.m.—Scientific Papers.

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. Bertil Lindblad: "The Dynamics of the Stellar Systems" (George Darwin Lecture).

Oil and Colour Chemists' Association, Manchester Section (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Annual General Meeting.

Sheffield Metallurgical Association, Methods of Analysis Group (at 198 West Street, Sheffield), at 7 p.m.—Mr. B. Bagshawe: "Absorptiometric Determination of Silicon".

Society of Instrument Technology, Midland Section (at the Chamber of Commerce Buildings, New Street, Birmingham), at 7 p.m.—Mr. E. E. Hancox: "An Introduction to pH and its Measurement".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Herman F. Mark: "Mechanical Properties of High Polymers as related to their Structure".

Saturday, April 10

British Psychological Society (at the University, Edmund Street, Birmingham), at 12.15 p.m.—Annual General Meeting.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Mycologist in the Plant Pathology Department—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (April 10).

Laboratory Steward for the Department of Zoology—The Clerk, Birkbeck College, Breams Buildings, London, E.C.4 (April 10).

Lecturer in Taxonomy (Zoology)—The Secretary of University Court, The University, Glasgow (April 14).

Vice-Chancellor, a Professor of Chemistry, a Professor of Mathematics, a Professor of Medicine, a Professor of Surgery, a Professor of Pathology, a Lectureship in Psychology, a Lectureship in Chemistry, a Lectureship in Economics, and a Junior Lectureship (Tutorship) in English, at the University of Hong Kong—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (April 16).

Educational Psychologist in the University Education Centre—The Secretary, The University, Edmund Street, Birmingham 3 (April 17).

Assistant Agricultural Economist in the Department of Agriculture—The Registrar, The University, Leeds 2 (April 19).

Lecturers or Assistant Lecturers in the Department of Physics—The Registrar, The University, Manchester 13 (April 24).

Assistant Archæology Officer—The Deputy Director of Establishment and Finance, Ordnance Survey, Leatherhead Road, Chessington, Surrey (April 26).

Assistant Lecturer in Chemistry (Inorganic and Physical)—The Registrar, University College, Singleton Park, Swansea (April 28).

Lecturer in Biochemistry, and Demonstrators (2, one in Biochemistry and one in Physiology)—The Registrar, University College of South Wales, Cathays Park, Cardiff (April 30).

Lecturer in Botany, an Assistant Lecturer in Mathematics (Pure Mathematics), an Assistant Lecturer in Chemistry (preferably with interests in Inorganic and Physical Chemistry), and an Assistant Lecturer in Botany—The Principal, Royal Holloway College, Englefield Green, Surrey (May 3).

Headships of the Departments of Physics, Mathematics, Chemistry at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (May 10).

Principal of the Canberra University College—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (May 15).

Assistant Chemists (Honours degree majoring in chemistry), an Assistant Chemist (Honours degree specializing in colloidal chemistry for research on rotary drilling fluid controls), Assistant Physicists (1st class Honours degree in physics with mathematics and some chemistry), a Chemical Engineer, and "Mud" (Trainee) Engineers (Graduate chemists with working knowledge of colloidal chemistry), to undertake research duties with a large industrial organization in the Middle East—The Ministry of Labour and National Service, Technical and Scientific Register, Room 669, York House, Kingsway, London, W.C.2, quoting F.263/47A (May 20).

Junior Lecturer in Applied Mathematics—The Secretary of Faculties, University Registry, Oxford (June 2).

MacLeod-Smith Chair of Biological Chemistry—The Secretary, The University, Aberdeen (June 15).

Principal of Auckland University College, Auckland—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (June 30).

Chair of Geology, and the Chair of Zoology, at the University, Sydney—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Sydney, June 30).

Lecturer in Bacteriology and Parasitology—The Principal, South African Native College, Fort Hare, C.P., South Africa (applications to be made by air mail).

Scientific Officer, and Assistant Experimental Officers (2), for research on the antibiotic substances of streptococci—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berks.

Assistant Engineer (Grade BI) for Filtration Research—The Clerk to the Metropolitan Water Board, New River Head, Rosebery Avenue, London, E.C.1, quoting Ref. N.

Chemist (Organic) for the Department of Chemical Pathology—Prof. N. F. Maclagan, Westminster Hospital Medical School, 17 Horseferry Road, London, S.W.1.

Scientific Officer to assist in research problems connected with steel castings—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Technical Engineer in the Department of Atomic Energy (Production)—The Staff Section, Ministry of Supply, Department of Atomic Energy, Risley, Warrington, Lancs.

Laboratory Assistant (Grade I) for the Physiology Department—The Secretary, King's College of Household and Social Science Campden Hill Road, London, W.8.

Chief Chemist to take charge of the work of the Chemical Department at laboratories at Elmstead Woods—The Director, British Scientific Instrument Research Association, 26 Russell Square, London, W.C.1.

Demonstrator in the Department of Physics—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1.

Junior Graduate Chemist in the photographic and chemical section of the Optical Department—The Superintendent of Laboratories, British Scientific Instrument Research Association, 'Sira' Southill, Elmstead Woods, Chislehurst, Kent.

Graduate B.Sc. in Chemistry or Biochemistry, with experience of hospital laboratory work—The Medical Officer of Health, Johnston Terrace, Edinburgh 1.

Senior Geologist for Mines Department, Adelaide—The Agent-General for South Australia, South Australia House, Marble Arch London, W.1.

FREEDOM AND LOYALTY

IN the course of his inspiring address on "The Scientist in Industry" to the Federation of British Industries at a meeting held at the Royal Institution on March 19 in honour of him and Sir Robert Robinson as Nobel Prize winners in 1947, Sir Edward Appleton referred to the vital importance of avoiding any segregation or isolation of research effort. He spoke also of the need for interpreting as liberally as possible whatever restrictions may have to be imposed in the interests of Government departments or industrial firms on men of science serving such organisations. Sir Edward's address was pervaded with a lively sense of the value of human factors; and above all of the importance of freedom of intercourse and movement; his words, indeed, contrast strongly with the restrictions which the Government announced a few days earlier on the employment of members of Communist and Fascist organisations in the service of the State. On grounds of national security, the Government has concluded that the only prudent course to adopt is to ensure that no one who is known to be a member of the Communist Party, or to be associated with it in such a way as to raise legitimate doubts about his or her reliability, is employed in connexion with work the nature of which is vital to the security of the State.

No reasonable exception can be taken to the terms of the Prime Minister's statement. The State, he said, is not concerned with the political views as such of its servants, and so far as possible alternative employment on the wide range of non-secret Government work will be found for those who are deemed to be unsuitable for secret work. Experience both in Great Britain and elsewhere has shown that membership of, and other forms of continuing association with, the Communist Party, may involve the acceptance by the individual of a loyalty which in certain circumstances can be inimical to the State.

However regrettable this decision may be—and there are consequences that involve some further consideration—no Government could pretend that there are not certain duties of such secrecy that the State ought not to employ in connexion with them anyone whose political discretion is in doubt. It shows a misconception of the Prime Minister's statement and purpose to urge that such action should only be taken after the individual concerned had had opportunity of appeal to some form of tribunal, or after weighing evidence by a judicial process. The point is that there is no specific charge brought against the individuals affected. As Mr. Attlee said, it is not suggested that in matters affecting the security of the State all Civil servants who adhere to the Communist Party would allow themselves to forget their primary loyalty to the State; but there is no way of distinguishing such people from those who might endanger the security of the State.

The Government in this precautionary measure has manifestly stopped well short of the point at which liberty and conscience are imperilled or economic sanctions raised against particular political creeds. Western democracy works by toleration and governs by consent, and the Government's moderation is in startling contrast to the methods pursued by Eastern communism—its rigid intolerance, intransigence and persistent attempts to over-run the frontiers of sincere democratic patriotism, and to crush freedom wherever it exists. To survey the plight of freedom in the satellite countries of the U.S.S.R. is to realize the enormous contrast, and also the moderation and realism of the British Government's action.

The University of Prague, which has been celebrating its sixth centenary, provides a case in point. In view of their information that for the time being the Charles IV University is subject to Government controls which deny to it the academic autonomy essential to all free and responsible university work, the universities of Great Britain reluctantly decided that their official representation at the celebrations would be inappropriate. Every university felt itself honoured by the invitation to Prague, and desired to pay tribute to the high and historic service of the Charles IV University to scholarship and science, and to the making of our common heritage of truth and freedom; but Sir Hector Hetherington, acting chairman of the Committee of Vice-Chancellors, has stated in *The Times* that it has seemed necessary to the universities to give no ground for the opinion that British universities are favourable to the changes wrought in the universities of Czechoslovakia.

That action, moreover, illustrates further a point made in a recent article in *The Economist*. There is urgent need, it was argued, for an effective counter-attack on communist activities and propaganda in all walks of life, in public affairs, in science particularly, and above all in the factories. Recent events have made a little plainer whither divided loyalties may lead us; but if the free nations are to preserve their liberties and their great traditions, they cannot continue to tolerate intolerance. They must, it is true, work out their own means of self-protection by their own democratic method; but they must not allow themselves to be deceived by the professions of those who reject these methods and only use them to subserve their purpose of intolerance and disruption.

In contrasting Sir Edward Appleton's words with the new policy, it should have been noted that in his plea for freedom he stressed the discipline of science. That should be the first loyalty of the man of science; and it is because that discipline and loyalty are rejected by the communist that science itself is endangered by communism as we know it in Soviet Russia. The totalitarian regime is inconsistent with the free pursuit of science, and professional workers would do well to address themselves more carefully to this question of professional loyalty. Without loyalty to the highest professional ideals and traditions, inherent in which is the tradition of faithful service to the society for whose welfare a profession exists, the pursuit of truth and the advancement of learning cannot long endure.

In this connexion Mr. Middleton Murry has a significant passage in his recent book "The Free Society"*. He is convinced that the contemporary confidence in the autonomy and invulnerability of science has no solid foundation. Science, he holds, is as vulnerable as the free society and is ultimately dependent on it. "'The matrix of science has been the politically free society, first in Greece, then in the final form of the Christian society. It was only when the Christian impulse, with the aid of the Roman tradition of law, had created for the intellectual freedom of Greek speculation a body politic which assured it of an abiding home that science, in the modern sense, became possible.' For science lives by a continuous tradition of scientific integrity, created and continually renewed by conscience. The scientific community is the child of the free society."

If Mr. Murry had done no more than direct attention to the new threat to scientific integrity which the spread of Russian communism offers, his book would have deserved attention. Men of science who were alert to the threat which the rise of Nazism and Fascism a decade and a half ago offered to science have sometimes been unhappily blind to the new danger. As Mr. Murry observes, members of the scientific community in the free society are frequently engaged in undermining that free society in the name of science, and there could not well be more alarming evidence of our peril. If the pursuit of research and of learning depends upon a consensus and community of consciences which are obtainable only within the free society, men of science must act in defence of that society.

That defence must be based upon understanding, and it is as a contribution to the clear thinking here required—which is the more imperative if the discrimination referred to in the Prime Minister's statement of March 15 is to be used wisely and without detriment to the democratic tradition or the growth of the free society—that Mr. Murry's book is most welcome. He is indeed challenging and provocative; and it would be a misfortune if the slightly dramatic character of the book diverted attention from the more fundamental issues which are raised.

What distinguishes the free society from other forms of society, according to Mr. Murry, is the prevalence within it of the fundamental liberties of the subject of freedom of conscience, of speech, of expression and of association. Those liberties are indeed subject to restraints, and he insists that it is by the achievement of tolerance that the free society becomes possible. Nevertheless, he argues cogently that in a world such as exists to-day, a free society can only be established by a government which, believing in the free society, is convinced of the necessity of refusing to tolerate the intolerant, and possesses the power to repress them with even-handed justice, both on the Right and on the Left.

Mr. Murry thus advances powerful reasons in support of the Government's decision; but in displaying the tension between the need for the satisfaction of conscience and the need for ordered society which the free society seeks to release, he brings to the front the immense moral issues involved. A free society, he says, lives by a firm belief that its citizens have the moral energy to correct their own mistakes, and to correct them before serious or irreparable harm is done to the fabric of the free society. It is a question of responsible power, conferred by the democratic process and exercised responsibly with respect to the rights of the minority and also to the welfare of the whole society. The free society, in fact, is a great experiment, and it is above all for his clear indication of the collective and moral responsibility of individuals and groups in Great Britain involved in this affirmation of the dignity, the freedom and responsibility of man that this book deserves to be pondered.

---

* The Free Society. By John Middleton Murry. Pp. 292. (London: Andrew Dakers, Ltd., 1948.) 12*s*. 6*d*. net.

There is first, as Mr. Murry justly observes, room for doubt as to whether the workers appreciate the necessity of dealing justly with one another or with society as a whole. Here his words should be weighed by the trade unions as well as by professional associations in general. Before the free society can be regarded as reasonably secure, the workers must be taught their new responsibilities.

That may well be the most important and urgent task a free society has to undertake; but with it, and of it, must go an increasing consciousness of the whole in existing groups and associations. An ordered society requires discipline ; but in a free society that social discipline must be a self-discipline ; and here, as Mr. Murry reminds us, is the importance of voluntary groups and associations within the free society. To the degree to which they are inspired by an understanding of the free society, they will establish the patterns of just legislation before the need of legislation becomes acute. They will anticipate the social disciplines which the free society needs.

Now while Mr. Murry pertinently reminds us that in the free society the loyalty demanded is no longer primarily loyalty to the fellow-members of a group or section but to the free society as a whole, it is as well to remember that there is a converse side. The disciplines voluntarily accepted in the free society are disciplines which must be accepted above, by the government, as well as the governed ; and they too must be inspired by an understanding of the free society as well as by a vision of its potentialities. To take only one instance at present in the public mind. It would be a grave mistake for the Government to imagine that the uneasiness of a large part of the medical profession over the new Health Act is not due to misgivings as to whether the profession will be able under the Act to give the public service which its professional ideals and traditions require it to render.

In dealing with the danger to the State of communist activities, a profound saying of Burke may be recalled : "It is no inconsiderable part of statesmanship to know how much of an evil ought to be tolerated". The Government has rightly decided that democratic principles do not call for the toleration of treason and terror, and it has wisely left it to the community to decide on the larger and fundamental issue, whether, in a democratic society, free scope should be given to those who seek to destroy democracy and to set up an intolerant regime.

If, therefore, the Government, in administering the decision, makes sure that impartial justice is done where the person concerned is not a member of the Communist Party but charged with "continuing association with it", it may well be claimed to have met Burke's test of statesmanship. That will not indeed avert the need for constant vigilance within and without Parliament. The debate on March 25 should have reassured those who fear that the cloak of security may be used to stifle the integrity of science and the ability of the scientific worker to serve mankind. But it is for scientific workers individually and in their professional associations to take up the challenge to fundamental thinking and constructive action which Mr. Murry throws down to them in "The Free Society" ; in that way only can freedom be ultimately safeguarded in science or among the free nations of the world.

FAMILY AND NATION

THE broadsheet series entitled *Planning* issued from time to time by P.E.P. (Political and Economic Planning) has produced many excellent and stimulating documents, and has made a valuable contribution to the solution of several of the social and economic problems with which Britain has been and still is confronted. The latest issue, entitled "Family and Nation", is, however, frankly disappointing. Much of the information in it is of great interest, and it raises many important issues which need to be raised and to be raised frequently. Admittedly the family is difficult to plan for, being so variable and so individual; and there is unconscious or perhaps conscious humour in the statement that it "must be strengthened in the functions for which it is peculiarly suited, such as the production of children". After an excellent section reviewing the fluctuation in the birth-rate, the introduction of family allowances, and the present state of income-tax rebates, the broadsheet goes on to outline a plan whereby the 'para-medical' services, together with marriage guidance, can all be combined in a family welfare service.

Such a proposal needs the most careful consideration at the present time, for it presupposes a large expenditure of public money and it also cuts across the recommendations of the Denning Committee[1]. Both are serious matters, and one would therefore expect weighty reasons to be given in support of the proposal.

The functions of the proposed new organisation would be to "improve the conditions in which children grow up, increase the number of 'wanted' children and help to reduce the number of children whose birth is not desired either by their parents or by the community . . ." This is a wide programme involving many issues, some highly controversial ; but the broadsheet suggests that "the existing arrangements for maternity and child welfare would provide a foundation" for implementing it, "other provisions being added as they were shown to be desirable and practical". But suppose for the sake of argument that the controversial difficulties had been surmounted and that the experts were agreed on such subjects as sterilization, abortion and artificial insemination; would not the case for incorporating these para-medical matters into the already existing maternity and health services, rather than vice versa, be overwhelming?

Marriage guidance deals primarily with the personal relationship of two people. It is true that there may be, and often is, a family in the background; but nevertheless it is the personal problems of two partners that are involved, and marriage guidance[1] as such cannot be undertaken merely as part of a larger service for the family. This is not to say that secondary questions such as childlessness and family planning do not come into the picture—they do very often—but they are incidental to the main problem. This is recognized in the Denning Report, which recommends that grant-aid be made to voluntary organisations engaged in marriage guidance. Yet the reasons given in the broadsheet for rejecting the recommendations of the Report do not seem to be convincing; "marriage guidance has such an important function to perform that there would be serious objections to leaving it outside the Family Welfare Service". What the serious objections are is not stated.

One may suggest finally that many couples, though willing that the State should ensure them a safe passage from the cradle to the grave, may prefer to keep their marriage relationships to themselves. This raises the larger question now under consideration by a Home Office committee, on what lines marriage guidance as a form of social service can be most advantageously developed. There is nothing in the broadsheet to indicate that this aspect of the question, namely, State interference in what is perhaps the most intimate personal relationship that exists, has been seriously taken into consideration.

[1] Final Report of the Committee on Procedure in Matrimonial Causes. Cmd. 7024. (London: H.M. Stationery Office, 1947.)

FOOD POISONING

Food Poisoning

Its Nature, History and Causation, Measures for its Prevention and Control. By Elliot B. Dewberry. Second edition. Pp. xii+246+24 plates. (London: Leonard Hill, Ltd., 1947.) 17*s.* 6*d.*

THE subject of food poisoning was once largely a series of disconnected observations and records of outbreaks; but during the last three decades the facts have been associated and the discrepancies and fallacies removed. For example, the old expression 'ptomaine poisoning' has been shown to be without meaning and entirely incorrect. Now it is possible to give a clear account of food poisoning, including the various causal agencies, the paths of infection and the reservoirs of the various bacteria responsible. In the first edition in 1943, the author of the book under notice gave a clearly written account of the subject, and the second edition has brought it up to date. The first edition dealt very inadequately with staphylococcus food poisoning; but this has now been remedied by the addition of a new, separate chapter of 22 pages on this subject which gives all the essential facts. An additional section (appendix I) on laboratory investigation of food poisoning cases is of doubtful utility, as this very technical subject is mainly of interest to the laboratory worker, and for him the account is barely adequate and is available elsewhere.

There are five main types of food poisoning, namely, *Salmonella* infections, toxin outbreaks due to special staphylococci, botulism, poisoning from contamination of the food with poisonous metals and other chemicals, and food poisoning from the consumption of poisonous plants, toxic mushrooms and other fungi, and poisonous fish or shellfish. Each group is separately and adequately treated. Most space is devoted to *Salmonella* food poisoning, which used to be, and may still be, the commonest type in Great Britain, and this is well done. The important recent work on the increase of this type of food poisoning due to the great increase in the use of dried egg mixtures is not mentioned; but this was probably too recent for inclusion.

Botulism is described in great detail, although not more than four outbreaks have ever been recorded in Great Britain. Its deadly nature justifies the detail, for it is more prevalent in some other countries. Food so infected usually shows signs of spoilage, but not invariably. This fact is just mentioned but should have been more emphasized, and the factors explained which determine whether signs of spoilage are or are not present.

The other types of food poisoning are adequately discussed, and no important inaccuracies were detected and few omissions. Examples of the latter are that cadmium poisoning should have been included in the chapter on poisonous metals, the value of the coagulase test is not given in discussing *Staphylococcus* poisoning and that more types of *Clostridium botulinum* are known than those mentioned. These are all small points, and the author has obviously been diligent to keep his book up to date.

The book is frankly a compilation not written by one personally an authority on the subject, but he has included all the essentials, and the volume may be accepted as an adequate and reliable account of food poisoning in its various manifestations. It is attractively illustrated and well printed.

ORGANISATION, METEOROLOGY AND WEATHER PREDICTION

"Here is the Weather Forecast"

By E. G. Bilham. (Binnacle Books Series.) Pp. 220 (36 plates). (London: Golden Galley Press, Ltd., 1947.) 10*s.* 6*d.* net.

WEATHER and the causes of weather are not easy subjects for the writer who addresses himself to a mixed audience. If he aims at strict accuracy, the writing must abound in saving clauses and qualifications, and the result will be anything but a clear-cut picture. Should he largely leave out the qualifying phrases, then the end result will not correspond to reality. Mr. Bilham, in this book, does manage to avoid these two dangers, and gives a clear and highly authoritative account of the way in which weather forecasts are prepared.

The account of the organisation for collecting and distributing weather observations, warnings and forecasts is excellent, and there is much highly interesting information about upper-air measurements by *radio-sonde* balloons and the war-time applications of radar to wind finding, and more recently to cloud observations. The importance of the work of the weather observers on land, on sea and in the air is rightly stressed, and a survey is given of their work and the instruments they use in making routine measurements of atmospheric pressure, temperature and humidity, wind speed and direction, rainfall and cloud height.

The preparation of weather charts and the meaning of the various pressure systems in terms of weather and wind are discussed, and the author valiantly attempts a non-mathematical explanation of Buys Ballot's law, or, strictly speaking, of Coriolis force. This, if a little inelegant because apparently different arguments are applied to meridional and latitudinal motion, serves to indicate the effect, although to a non-mathematical reader the exact variation with latitude will not be readily seen.

The reader is introduced to the extremely important notion of air masses and fronts, which did so much to improve forecasting when first recognized during the First World War and is still the basis of forecasting up to twenty-four hours ahead.

In a book rich with information one hesitates to ask for more; but an account of the different effects on weather of coastal waters, as between winter and summer, and the modifying effects of high ground and long passage overland on cloud and weather, would have been extremely valuable. A man in London hearing overcast conditions and maybe drizzle forecast for south-west England on a fine August morning would then go his way confident that for once the weather is not spreading east.

The principal causes of bad forecasts are lightly touched upon; but many meteorologists would wish that more stress had been put on changes in the weather associated with fronts as they cross Great Britain in particular. After all, if it rains two or three hours after the forecast time, that is a small thing to the man in the street; if it does not rain at all he is little impressed by being told that the warm front passed him exactly on time!

Within the two hundred pages of this book there is a vast amount of information; but the reader is not likely to feel he is being crammed: the frequent plates (there are thirty-six of them in all) and clear line diagrams aerate the text, and Sibley's drawings do much more than illustrate points in the text.

M. K. Miles

MATHEMATICS FOR ELECTRICAL ENGINEERING

Modern Electrical Engineering Mathematics

An Introduction to the Mathematical Methods more Recently Employed in Electrical Engineering Theory, with Special Reference to Stationary Linear Networks. By S. Austen Stigant. Pp. 372. (London: Hutchinson's Scientific and Technical Publications, n.d.) 31*s*. 6*d*. net.

THERE are few branches of mathematics which have not found useful application to electrical phenomena, and the engineer is continually receiving new tools of a theoretical nature to add to his equipment. He has long since had to become familiar with the use of infinite series, with Fourier analysis and with many of the differential equations and functions of mathematical physics. More recently, however, matrix theory and tensor analysis have been added to the list, and the operational methods of approach to circuit problems, including that of the Heaviside calculus, are becoming increasingly important.

In these circumstances, many engineers must be wondering whether it is better to be thoroughly conversant with a limited field of mathematics, so as to be able to make the fullest and most practical use of the knowledge they possess, or to understand in a general way the vast mass of symbolic theory available for their use, with little hope—unless, indeed, possessing an unusual faculty for mathematics—of being really proficient in any of it. There is no general solution to this very real dilemma; it depends upon the individual concerned and upon the degree of specialization within which he works. The author of the book under notice believes that no branch of mathematics likely to have practical application should be neglected by any engineer on the score of its being new or unnecessary: "The advanced engineering theories of to-day become the commonplace practice of to-morrow". It is likely that most engineers would so far agree as to admit the desirability of being at least aware of what analytical methods are available and of their useful range of application.

From this point of view, Mr. Stigant's book is to be welcomed. It deals with a limited number of subjects, having nothing to say concerning differential equations, infinite series or function theory generally, all of which have been discussed adequately before. More than half the book (ten of the eighteen chapters) is concerned with determinants, matrices and tensor algebra; the Heaviside operational calculus, symmetrical components and dimensional analysis in its various forms account for five chapters. The book is thus probably the most comprehensive account of these subjects—with the exception of the operational calculus—that has so far been written for engineers.

The many branches of theory discussed and the large amount of space legitimately and usefully devoted to engineering applications might lead one to anticipate a less detailed treatment than is, in fact, given. On the contrary, a criticism of the reviewer—albeit a minor one—is that in some instances, particularly perhaps in the chapters on tensors, the discussion could be more concentrated. Nevertheless, the writing is careful, and pains have been taken to stress the connexion between the different analytical methods of approach to problems. The original Heaviside method is used in the chapter on operational calculus; the Laplace transform approach is usually preferred nowadays, although the reviewer would agree that, for many, the method adopted in this book would seem a more natural way of introducing the subject. The equivalent of perhaps five chapters is given to examples illustrating the theory, including, among others, the steady state and transient response analysis of networks, three-phase systems, line faults and line protection. Many examples are solved by more than one method.

The book does not make easy reading, which is a fault of the subject rather than that of the author. It could scarcely be recommended as useful reading, however, to anyone who was not already quite familiar with the more usual mathematical methods applied to engineering problems.

There seem to be few errors, and although the production is in conformity with war economy standards, the clarity and lay-out are good. Most useful features are the bibliographies which are given at the end of nearly every chapter. V. J. Francis

ADVANCES IN PHYSIOLOGY

Annual Review of Physiology

Victor E. Hall (Editor), Jefferson M. Crismon and Arthur C. Giese (Associate Editors). Vol. 9. Pp. vii+736. (Stanford University P.O., Calif.: Annual Reviews, Inc.; London: H. K. Lewis and Co., Ltd., 1947.) 6 dollars.

THE "Annual Review of Physiology", though published in the United States, was intended to be international in authorship. It started in 1939 and during the War it had to remain, as it had begun, entirely in American hands. The present volume marks the first appearance of European contributors, who are responsible for five of the twenty-seven articles. Next year we are promised two contributions from the U.S.S.R.

This volume maintains the standard of its predecessors and, as is usual if not inevitable, the articles are of very unequal merit, ranging from the hasty compilation of a catalogue of references, to the personal and critical writing of one who has taken the trouble to digest the data under review. In the latter category are three outstanding contributions of general physiological interest. F. Buchthal, in his article on muscle, summarizes the brilliant contributions which he and Szent-Györgyi have made in elucidating the role of actomyosin and adenosine triphosphate. He also deals fully with the vexed question of the status of acetyl choline in neuromuscular transmission, and covers the advances in electromyography which have resulted from war-time research on peripheral nerve injuries. H. Grundfest, dealing with bio-electric potentials in the nervous system and in muscle, presents a very intelligible review of a subject which to many physiologists has become increasingly obscure. The data are carefully sorted out and correlated; the conflicting theories are precisely defined and then critically analysed. C. J. Wiggers, reviewing the peripheral circulation, gives a characteristic and critical appraisal of some of the newer techniques, such as cardiac catheterization. The main feature of his article is a very thorough discussion of the peripheral resistance, which may well become a classic. Recent work on shock and hypertension is also covered.

In his article on exercise, P. V. Karpovich directs attention to the surprising lack of elementary data in this important and practical subject. Some new physical-fitness tests are discussed, recent work having shown the old tests, such as breath-holding and pulse return after exercise, to be of little value. Workers in several different fields have made the rather surprising discovery that many gross nutritional deficiencies have little or no effect on physical performance of short duration. It is also reassuring to read that rats live longer in an atmosphere of tobacco smoke.

Pathologists will find two articles of particular interest. Writing on defence mechanisms, W. C. Boyd and S. Malkiel review the important work of Menkin, who has isolated various factors—pyrexin, necrosin, leucotaxin—from inflammatory exudates. They also attempt to cover the wide field of antibody–antigen reactions and detoxification mechanisms. S. P. Reimann's article on growth deals chiefly with the pathology of growth and is a most interesting account of attempts which are being made to apply recently acquired biological knowledge to some of the classical problems of pathology. For example, the concepts of induction, evocation and organisers derived from embryology are being applied to the study of mixed tumours. Aberrations of growth resulting from nutritional deficiencies open up a promising field, and the trial of various specific growth-inhibiting substances in the treatment of cancer and leukæmia is interesting, although the results so far have been disappointing.

F. K. Sanders, writing on cutaneous sensation, gives a useful summary of the important work of Woollard and Weddell, most of which was published during the War and is already well known in Great Britain. The physiological effects of heat and cold still require a separate article owing to the considerable amount of war-time research which is still appearing. In this article A. P. Gagge and L. P. Herrington attempt a scientific appraisal of some of the experiments carried out by the Germans at Dachau, and add some appropriate ethical comments. War research still accounts for much of the material reviewed under blood gas transport by D. B. Dill and W. H. Forbes, and also under the respiratory system by H. C. Nicholson. W. Dock, writing on the kidney, devotes less space than usual to consideration of the various 'clearances', which he prefers to call 'ratios', and gives a very welcome review of renal morphology and pathology, especially in its relation to shock and hypertension. Under pharmacology, C. C. Pfeiffer and E. R. Loew deal with the new antihistamine drugs; but most of their article is devoted to chemotherapy and deals with newly discovered chemicals active against fungi, viruses, rickettsia, rodents, war gases and cancer. Two new subjects not previously reviewed are the physiology of supporting tissue by P. D. F. Murray, which deals chiefly with bones and teeth, and the experimental neurosis by H. S. Liddell. The articles on metabolic functions of the endocrine glands by F. D. W. Lukens and permeability by W. Wilbrandt present a vast amount of new information from which no very striking advances seem to emerge. O. A. TROWELL

BIOLOGICAL APPLICATIONS OF ULTRA-VIOLET AND INFRA-RED RADIATION

Applications of Germicidal, Erythemal and Infrared Energy

By Dr. Matthew Luckiesh. Pp. ix+463. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1946.) 30s. net.

THE author of this book is the director of the lighting research laboratory of a large electrical firm in the United States and is well known as a prolific contributor to the technical literature of his subject. Much of the material in the present volume has appeared in various technical publications; workers in the field of radiation and its applications will be glad to have the data collected together in a single volume. The scope of the book, the stated object of which is to deal with some major effects of radiant energy, is perhaps sufficiently indicated by the title.

The science of radiation therapy, with which the book is largely concerned, is still in its infancy. Few will dispute the health value of sunlight, although some may question how far this is of psychological origin or the result of associated fresh air and exercise. The benefits to be obtained from exposure to so-called artificial sunlight are far more open to question. This is only one of the controversial subjects discussed in the book under review—discussed, one may add, in no controversial spirit, for the author states his case with almost evangelical conviction which leaves little room for heretical questioning.

One of the most interesting sections of the book is that dealing with the germicidal effects of ultra-violet radiation. The importance of this subject is now fully established and is well brought out in the excellent symposium on aerobiology published in 1942 by the American Association for the Advancement of Science. In Great Britain experimental germicidal lamps have given good results in certain industrial processes which have to be carried out under sterile conditions. British medical interest in the bactericidal possibilities of ultra-violet radiation has, however, been slow to develop.

The book seems to have been put together hurriedly and is, in consequence, sorely in need of careful editing and vigorous pruning. There is much needless repetition and overlapping; some of the sections, for example, that on ultra-violet energy and plant life, are inconclusive and do not appear to lead anywhere. Too much space is devoted to the author's proposals for systems of units for biological effectiveness of ultra-violet energy analogous to those in use for visible radiation. It may, perhaps, be questioned how far these are justified or will find general acceptance.

Most of the discussions centre around the work of the author and his colleagues; there is, however, a fairly comprehensive bibliography. The various discharge lamps and other artificial sources mentioned are those commonly marketed in the United States, but similar sources are available in Great Britain and elsewhere. Despite its defects, the book should be studied by all who are interested in the biological effects of radiation within the range of the sun's spectrum.

H. G. Jenkins

THE ARGUMENT FROM MOUSE TO MAN

Animal Genetics and Medicine

By Dr. Hans Grüneberg. Pp. xii+296. (London: Hamish Hamilton Medical Books, 1947.) 21*s*. net.

Dr. Grüneberg's new book covers some of the same ground as his well-known monograph on the "Genetics of the Mouse". But the genetic facts he brings forward, although drawn from a narrower field than might be expected from his title, relate to the rodents as a whole rather than to the mouse in particular. His volume provides, in a simple and readable form, the most complete available summary of our knowledge of inherited pathological conditions in this whole group, and will be, for that reason alone, extremely welcome to genetical workers in other fields. As in his previous book, it is a particularly valuable feature that he describes not merely the final adult form of the abnormality, but also as much as is known of its developmental antecedents.

The purpose of the book goes much beyond that of a mere summary. Dr. Grüneberg has written his book in the hope "that it will help to make the geneticist more fully alive to the medical value of his material, and that it will show the medical practitioner that invaluable sources of information are only waiting to be opened up by him". The application which Grüneberg wishes to make of the wealth of factual material he presents is partly at a theoretical level. He shows how the animal geneticist, by the use of controlled breeding, can easily discover whether two apparently rather different abnormalities are, in fact, due to the same ultimate genetic cause. If they are, they may legitimately be considered as two aspects of a single unitary disease. An argument of this type is, the author holds, the only kind which can make possible a logically unassailable classification of the clinical conditions in which hereditary disposition plays a large part. Unfortunately, the crucial test of breeding cannot be applied in a controlled manner to human material; but less direct ways of applying the same concepts are sometimes feasible, and the genetic criterion at least indicates the goal towards which effort should be directed.

The other main advantage enjoyed by the animal breeder is the ability to produce as many animals as he pleases of the pathological strain. This makes it possible to carry out an adequate analysis of the epigenetic processes by which the abnormality is produced. Grüneberg has himself made several noteworthy advances in this connexion, showing, to mention only one example, how a complex of apparently unrelated effects in a certain strain of rats may be traced back to an initial hypertrophy of the cartilage. Such studies are scarcely possible for human material. Indeed, some medical men may be tempted to dismiss them as unnecessary for clinical practice, since there is still a tendency to consider pathological conditions as either physiologically conditioned (when they may be curable), or as hereditary (in which case nothing, it is assumed, can be done to obviate them). Such a view is, of course, indefensible. Grüneberg quotes with approval Sewall Wright's dictum that "the attitude of physiological genetics is that characters are determined 100 per cent by physiological processes, and that genes are the ultimate physiological agents". Genetics has already made an important contribution to the detection and conservative treatment of sub-clinical diabetes, and it may be expected to render many more such services to therapeutics.

The numerous genetically controlled developmental processes described by Grüneberg have an important bearing on the fundamental biological problem of the mode of action of genes. In discussing these, the author is perhaps not always so convincing as when he is exhibiting the relevance of his material to medical questions. For example, the discussion of whether gene-action is organ-specific or tissue-specific is surely based on a question which does not go deep enough. Some genes, if classified in such terms at all, could only be called organ-specific (for example, aristopedia or bar eye in *Drosophila*); others would appear (contrary to Grüneberg's statement) to affect more than one type of tissue (for example, the 'white' gene in *Drosophila* also reduces pigment in the testis sheath). Surely the true state of affairs is that a gene is specific for one chemical process, which may be involved in one or a number of different tissue- or organ-differentiations.

C. H. Waddington

Elementary Applied Aerodynamics

By Prof. Paul E. Hemke. (Prentice-Hall Aeronautical Engineering Series.) Pp. viii+231. (New York: Prentice-Hall, Inc.; London: Constable and Co., Ltd., 1946.) 26*s.* net.

THIS American volume is essentially a tutorial or class text-book of the type that has not yet made extensive appearance in the field of English aeronautical literature. It treats the subject in logically arranged chapters, each one ending with a number of examples. These are both of the kind that emphasizes the theory already explained, and those giving the technical application of the subject-matter of that chapter. References in these questions to the relevant parts in the discussions, by means of a decimal system of numbering the paragraphs and conclusions reached, make the whole book extremely easy to follow, in a tutorial sense. As an examination crammer it is splendid; whether it is advisable to spoon-feed a student to such an extent is another matter.

The reader will have to take a good deal of the data for granted, especially that given in many of the charts, as reference to the source of the information is not always given. This is, of course, inevitable in a book that attempts to compress the subject into so small a space. It also dates the book rather badly, as the inquiring reader will find it difficult to link up the subject-matter with more recent advances. Aerodynamics is treated in a series of chapters on units, physics of the air, the ideal fluid, viscosity, compressibility, the properties of airfoils, propellers, performance and the helicopter. The author states in his opening remarks that he has dealt with only "the consideration of the more well known and established facts in aerodynamics". The book obviously has been written with the outlook of the exercise class, and in this limited field it can be recommended.

Mathematics of Statistics

By John F. Kenney. Part 1. Second edition. Pp. xii+260. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1947.) 21*s.* net.

THIS is the first volume of a second edition of a book first published in 1939. The complete book is intended to be an introduction to the more elementary theory and methods of mathematical statistics. The present volume confines its attention almost exclusively to the descriptive theory of statistics. Within this limit, it provides a very carefully and clearly written and admirably printed introduction to the subject, well suited to a student without mathematical knowledge, or working alone. After chapters on the description of frequency distribution by graphical methods, averages, moments and measures of dispersion, the normal distribution is shortly considered, followed by the fitting of linear and quadratic polynomials and the theory of correlation. These subjects are explained with great clarity and at considerable length; but it seems a pity that in so large a book, costing so much, no room was found for an elementary account of sampling and the testing of statistics. As a consequence the student who wishes to decide how much reliance to put on the results of his calculations will have to turn to volume 2 or some other book. This volume by itself is therefore not very useful to a biologist or other experimentalist.

P. A. Moran

La lutte contre les termites

Par Ch. Noriot et H. Alliot. (Publication de l'Office de la Recherche scientifique coloniale.) Pp. 96. (Paris: Masson et Cie., 1947.) 220 francs.

IT may be said, at the outset, that this publication provides the best short modern account of termites and their control. It is, furthermore, extremely well illustrated and admirably printed on very good paper. The first part deals with the general biology of termites and the outlines of their classification. Part 2 is devoted to the application of various methods for destroying these insects, and Part 3 describes in some detail, and with many structural diagrams, the best methods for protecting woodwork against termite attack, and the special features needed in building construction in guarding against their depredations. Each section is accompanied by a short but adequate list of references to the relevant literature that may be consulted. There is also a list of the various trees stated to be resistant to termite injury.

A. D. I.

Honey Farming

By R. O. B. Manley. Pp. 293+15 plates. (London: Faber and Faber, Ltd., 1946.) 18*s.* net.

MR. MANLEY, who is one of the very few people in the British Isles who can claim to be a honey farmer and to maintain successfully a large number of colonies of bees, is a person whose opinion on all matters relating to bee-keeping is well worth hearing. His latest book, "Honey Farming", is a worthy successor to his earlier excellent and widely read work "Honey Production in the British Isles".

In this new book Mr. Manley draws upon his wealth of practical experience and, in an eminently readable manner, gives some of his ideas about bee-keeping and the methods of management that he is using to-day, relating not only something of his successes but also telling of his failures and how the methods that he is now employing were gradually developed. Needless to say, he thoroughly disagrees with many of the methods still taught and practised by some of the less well-informed bee-keepers, and he does not hesitate to say so, or to criticize severely some of the equipment still advocated for general use. Indeed this book, besides being of inestimable value to those people who wish to learn what a man who has been successful in earning a living from honey production thinks about various systems of management, apiary equipment, bee-breeding, swarm control, queen introduction, and much else besides, will also be a tonic to those who have wished for so long to see the archaic nonsense still talked about bee-keeping exposed.

This is indeed one of the few books about bee-keeping that one can unreservedly recommend, and one that I hope will find a place in the library of every bee-keeper.

C. G. Butler

Dairy Farming

Theory and Practice. By V. C. Fishwick. (Agricultural and Horticultural Series.) Pp. 237+55 plates. (London: Crosby Lockwood and Son, Ltd., 1947.) 15*s.* net.

A FEATURE of this book is that about half of it is devoted to concise descriptions of the methods and views of twenty dairy farmers. Six of these farmers are said to be men with a national reputation, seven are well known in their own locality and the remainder are representative examples of the ordinary farmers of Great Britain. The accounts, which cover a wide range of current practice in dairy farming, are readable and enlightening; and they are illustrated by a useful selection of photographs.

The other half of the book purports to deal with the scientific principles of dairy farming; but this section is singularly rambling for a scientific work and the principles are diluted with platitudes. The diction is sometimes puzzling; for example, when the author states "A skilful breeder will frequently raise a herd of animals that are very similar to the eye". Many of the definitions are inept, and a new agricultural student might be misled by reading that a starchy food is one that contains a small amount of protein.

The general conception of the book and part of the contents are excellent; the style of the remainder will have a limited appeal, but in any case should be read in conjunction with more authoritative works.

S. B.

Birds of the Southwest Pacific

A Field Guide to the Birds of the Area between Samoa, New Caledonia and Micronesia. By Ernst Mayr. Pp. xx+316+3 plates. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1945.) 18*s.* net.

THE south-west Pacific, that is, the area between Samoa, New Caledonia and Micronesia, is a rich ornithological field, many interesting and varied species of birds being found in it. This little book is a field guide to them, its author, Dr. Mayr, having worked for many years on Pacific ornithology. In his introduction he points out that the difficulties and the interest of the task are enhanced by the many separate archipelagos involved, each with its distinct bird fauna, though certain species are common to many if not all the archipelagos. He therefore divides his book into a general section and a geographical section, dealing with the seabirds, shorebirds, and land and freshwater birds of the area in the first part, and taking the faunas of the different groups of islands separately in the latter section. The coloured plates and the black-and-white sketches are helpful and enhance the value of a very useful book.

FRANCES PITT

Archéologie du Pacifique-Nord

Matériaux pour l'étude des relations entre les peuples riverains d'Asie et d'Amérique. Par Dr. André Leroi-Gourhan. (Université de Paris: Travaux et mémoires de l'Institut d'ethnologie, Tome 47.) Pp. xviii+542. (Paris: Institut d'Ethnologie, 1946.) 700 francs.

THIS volume deals with the archæology of the North Pacific in two parts. The first deals with the area generally and with the inhabitants of different regions severally—Japan, the Ainu, Kamschatka, the Eskimo of four different regions, and the Aleutian Islands and British Columbia. In the second part the author takes some fifteen or sixteen implements of common use and widespread occurrence, analyses the various types, and shows their distribution on sketch maps. The Eskimo in particular afford a remarkable instance of an extremely wide distribution of material types, due in part to their possession of a common language and culture, in part to the extremely small and scattered population using the artefacts in question. Life in the North Pacific is necessarily dependent on a highly specialized material culture in which the nature of every tool is strictly determined by the physical environment.

The author comes to the conclusion that it is possible in a sense to speak of a North Pacific civilization, but he rejects any suggestion of a common focus of culture or of the importation of a formed culture from outside the area dealt with. He points out that the remotest period covered by archæological finds cannot be shown to be more than two thousand years ago; that during all that period the population of the area concerned has possessed a comparatively stable physical type; and that the distribution of various types of artefact indicates lines of communication, not of migration. He infers, in consequence, the general danger in archæology of building up theories of migration on the data of typological distribution. Human movement is much less frequent and very much slower than the movements of material culture.

The volume contains a good bibliography of wide range in date and language, a rather poor index, forty-three good maps mostly of distribution, and 1,148 text figures. The work is an important one not only as a study of North Pacific cultures, but also in reference to archæological method in general.

J. H. HUTTON

The Navaho

By Clyde Kluckhohn and Dorothea Leighton. Pp. xx+258+20 plates. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1946.) 25*s.* net.

THE recent increase in the Navajo population and the reduction in fertility of the land in their reservation, consequent upon soil erosion, has confronted them with a serious material problem. Their contact with the civilization of the white man has aggravated this and introduced an equally grave spiritual problem. The Indian Field Service is doing its best to help them; but the policy of moving the administrators from tribe to tribe on promotion prevents them from really getting to know any of the Indians.

This book is one of a series of tribal monographs published on behalf of an Indian Education Research Project sponsored by the University of Chicago and the U.S. Office of Indian Affairs. It deals primarily with Navajo life at the present time, and is designed chiefly to instruct the administrators and teachers who work among these people. The deep concern of the authors for the welfare of the Navajos is shown by it and other books which they have written, and it is a useful, though necessarily limited, study of culture contact, based on intimate knowledge. How far their audience lags behind them is shown by the fact that they find it necessary to insist, at some length, upon such elementary matters as the importance of acquiring at least a smattering of the Navajo language.

That the Navajo word for themselves can be translated 'people' or 'the people' is by no means an isolated phenomenon, so the frequent reference to them as The People, which recurs throughout the book, is an irritating mannerism. The production of the book is up to the high standard which we expect of the Harvard University Press, and it is illustrated by some admirable photographs.

G. H. S. BUSHNELL

SCIENTIFIC ASPECTS OF THE WORK OF THE NATIONAL COAL BOARD

By JOHN CROSSLAND

Department of Mining, University of Leeds

Introduction

UNDER private ownership, only a few of the larger colliery companies in Britain had laboratories and research departments, and apart from an effort to control the standard of coal preparation, little real scientific investigation was carried out by the colliery companies themselves; at any rate, judged by present-day standards, it was totally inadequate. To some extent, various research organisations—largely sponsored by the Mining Association—compensated partly for this deficiency; but, here again, the scale of attack was not large enough.

When the Miners' Welfare Committee came into being and a levy of 1*d*. per ton of output was arranged, some of this money was used to create the Safety in Mines Research Board. Work carried out by this Board was directed towards increasing the health and safety of those employed in the coal mines of Britain, and much useful work was accomplished. Naturally, the aim was to improve working conditions, study safety appliances and generally to find ways and means of reducing the number of accidents.

There was also the British Coal Owners' Research Association, where some work was done on mine atmospheres, suppression of dust, drilling and spontaneous combustion; but the staff was never large.

Just prior to 1939, the British Coal Utilisation Research Association, to which the Mining Association subscribed most generously, commenced work on a number of programmes connected with the efficient utilization of coal for both domestic and industrial purposes. This organisation was able to assist the various industries in many ways during the war period. It must be remembered that when the National Coal Board took over the vast mining industry of Britain, it did so at comparatively short notice and with almost no preparation for the gigantic task before it. Some of its plans are now being made known, and among them it is not surprising to find that the Coal Board proposes to develop a scientific department in the fullest sense.

Although the organisations mentioned previously were doing useful work before January 1, 1947, it was obvious that considerable expansion would be necessary as deeper, dirtier and more difficult seams were mined. An increase in the amount of mechanization will take place, with a consequent increase in the use of power, both on the surface and underground. Therefore, research should be directed towards obtaining a solution to the many problems that will occur, so that plans for the changes can be formulated well ahead, in order to obtain the highest standard of efficiency in all branches of mining work.

In the various coalfields, there has existed for many years, and usually attached to a university department of mining, a coal survey laboratory. These laboratories were financed by the Department of Scientific and Industrial Research, for the purpose of making chemical analyses and physical examinations of the seams in the area and for providing information of national importance in connexion with the future working of the coal seams. The results of this work have been available to all colliery companies in the past, and the National Coal Board has taken over these laboratories as a going concern, to be placed under the direction of the scientific member of the Board.

Status of Scientific Department

The National Coal Board decided, from the commencement of its existence, quite rightly, that science should be brought into the mining industry in the fullest sense, and that it should be represented at the highest level. It was not surprising, therefore, to find that Sir Charles Ellis had been appointed as the scientific member of the Board. This was decided so that a scientific approach could be made to all problems, whether under the heading of control or research. It is intended that a scientific organisation shall be built up to become an integral part of the industry, and not something quite extraneous to it.

A divisional 'chief scientist' has been appointed in each division, that is, each coalfield approximately, not as a member of the divisional board, but as an adviser to it. The divisions are split up into areas, and in each area there is a 'scientist' and a staff, so that it will be possible to provide a comprehensive scientific service, which will be at the disposal of the area general mines manager. In time, modern laboratories and equipment will be available in all coalfields, and, when the necessary staff can be obtained, much useful work may be accomplished in a field where there is a wide scope for work of this kind. Eventually, at the divisional level, laboratories will be available, with a specialist staff, to tackle problems which are beyond the resources of the area laboratories, and which are of special interest to the particular division. In this connexion, it should be mentioned that each coalfield has its own particular problems; for example, South Wales, production and suppression of dusts which cause pneumoconiosis; Staffordshire, Warwickshire and South Yorkshire, spontaneous heating and gob fires; West Yorkshire, working thin seams; north of England, preparation and cleaning of gas coals.

There are many problems which are found in all coalfields: pit heap fires, treatment of effluents, testing of suggested new analytical methods, the routine examination of the prepared coal and coal preparation problems generally. Routine scientific work includes analysis of coal, mine air, mine dusts, cokes, oil and metals, physical tests on coal, analysis and treatment of water (particularly for boiler plants and in some instances for domestic use).

In an effort to decentralize the scientific control service, it is intended that the day-to-day work of control should be determined by the division, in accordance with standard methods and standards of accuracy laid down by the Board. This is so that laboratories will be similar in status, arrangements and staff. A 'director of scientific control' has been appointed to co-ordinate the work in the various divisions.

As mentioned previously, the national coal survey has been transferred to the Coal Board, and the laboratories will co-operate with the divisional scientific organisations, with the Geological Survey and with the Fuel Research Station at Greenwich.

National Research Directorates

Many of the research problems concern all the coalfields of Britain, and therefore cannot be investigated at divisional level. In order to obtain the maximum of efficiency, the full weight of the headquarters staff will be necessary to deal with these problems. Provisionally, three research directors have been appointed at national level: (*a*) chemical, (*b*) medical, (*c*) physical. Under (*a*), much of the long-term research will be on the 'physics and chemistry' of coal, the carbonization and manufacture of special fuels and the development of chemicals from the by-products of coke and gas. The majority of this work will be carried out at Newcastle and in South Wales, and will be co-related with that of the British Coal Utilisation Research Association, where work is being done on the efficient utilization of coal. Under (*b*) the chief problem will be the health of the miner. The present director is a physician, and in the first place investigation will be made on such occupational diseases as pneumoconiosis, nystagmus, dermatitis, rheumatism, beat-hand and beat-knee. There are in existence organisations which have already carried out some work on these diseases; but much can be done by co-ordinating their efforts, and in the dissemination of knowledge obtained. Very often the latest information never reaches the miner, who, like many men employed in rather rough and tough jobs, tends to be careless about his health. Statistics relating to diseases and accidents will be examined, and special men and collieries will be selected for experimental purposes, as these problems have to be considered from the medical, physiological and operational points of view. An effort is being made to recruit an adequate and properly qualified staff.

General Research

It is important that all questions of a fundamental character which affect underground working conditions should be investigated. In the first place, the 'director of general research' is concentrating on mine dusts and illumination. With regard to the latter, for example, it is necessary to produce lighting of a character which is suitable for different coal faces. Pneumatic fluorescent lamps are being tried, and, generally, mine lights of numerous types are being studied in relation to the various methods of working, which include the use of many classes of machinery. It is obvious this work has considerable bearing on the prevention and alleviation of certain diseases such as pneumoconiosis and miners' nystagmus. The National Coal Board has taken over all the liabilities of the Mining Association with regard to research, and therefore becomes the largest subscribing member of the British Coal Utilisation Research Association. Sir Charles Ellis has been elected president and chairman of the council of the Association. This will allow of the necessary liaison between these large organisations and will ensure that all research work on coal will be co-ordinated, and much overlapping of programmes of research thus avoided. In order to facilitate the interchange of ideas between the Board and the research organisation, the scientific member's deputy—the director-general of research—has been made responsible for the efficient organisation of the scientific aspect of the Coal Board's work, and a small staff will be engaged on routine administration, so that the scientific workers employed will be free from restrictions of this kind.

The ground work has been accomplished, and much of the machinery created for the scientific study of the British coal industry's problems; but it is premature yet to look for major results. There is unlimited scope for the Scientific Department when it is properly equipped and staffed.

THE FUTURE OF THE NEW FOREST

THERE is probably no part of England which is the subject of more general interest than the New Forest. Everyone in the country has become acquainted as a child with at least one historical fact associated with the New Forest, and has since acquired some information—probably inaccurate—as to the real significance of both parts of its name; even if he has never visited it, he feels that it is part of the national heritage which should be preserved as such.

Those who live in or near the Forest, those who know it well as visitors, and those who have some part to play in its use and maintenance, have naturally all been keenly interested in the effect modern developments and ideas are having or may in future have on it; and the result has been a series of official publications on these subjects—as well as numerous unofficial reports and papers—of which the latest is the "Report of the New Forest Committee, 1947"*. The Committee in question was appointed by H.M. Forestry Commission in April 1946, "to investigate the state and condition of the New Forest and, having due regard to existing rights and interests, to recommend such measures as they consider desirable and necessary for adjusting the Forest to modern requirements". The membership of the Committee should be noted, comprising a distinguished representative each of the English National Committee of the Forestry Commission, of the Council for the Preservation of Rural England, and of the Forestry Commission itself, under the chairmanship of the Right Hon. H. T. Baker. From the list of eighty-four witnesses heard, it is evident, despite one or two gaps, that every effort was made to hear all informed and interested points of view—and incidentally the Committee met no fewer than thirty-five times.

The two committees responsible for the previous reports of 1939 (Report of the Committee of Planning Officers, 1938–39, H.M.S.O.) and 1945 (Planning Officers Report; Planning Committees Revision, 1945; New Forest Advisory Planning Committee, Lyndhurst) were primarily composed of representatives of the local government authorities most concerned, and dealt specifically with the protection of the New Forest as related to local and regional planning. The deputy-surveyor, Mr. D. Young, has served on all three committees, and much of the credit is due to him for the very considerable measure of success attained in reconciling rather conflicting views and interests, and the significant improvement of the relations between the major interests which has been brought about in recent years.

This is perhaps not the place to examine the legal aspects of the problem, important and interesting though they are; but it must be noted that the present situation is mainly governed by the New

Forest Act of 1877, many clauses of which are shown to be in need of clarification or revision. It has also to be realized that since 1923, when the management was handed over from the Office of Woods to the newly constituted Forestry Commission, the Forest has ceased to be Crown property. Appreciation of the value of the Forest from the point of view of recreation and enjoyment can be traced back to 1868 at least, and in 1928 it was declared in Parliament that amenity should be the chief object of management, and positive steps were taken to ensure outstanding appropriate treatment of areas of interest, with the help of an advisory committee.

A matter which has long been the subject of the keenest interest and concern is the enclosure of parts of the area for forestry purposes. Out of the total area of 92,365 acres, 64,707 are Crown Lands, and at the time of the Deer Removal Act (1851) it was agreed that the enclosures might total 20,000 acres, this figure being afterwards reduced to 16,000. The actual areas enclosed were not fixed in perpetuity, but only the maximum area that may be enclosed at any one time, so that an area successfully stocked with trees might be thrown open and an equivalent area elsewhere taken in. The present position is that 15,745 acres are enclosed and the balance of 255 may only be taken up within 1,927 acres which, though now unenclosed, have been enclosed in the past. An interesting historical point is that enclosures to protect young coppice were expressly provided for so long ago as an Act of 1483, and 6,000 acres were actually so enclosed in Elizabethan times. It should be noted that there are 5,000 acres of unenclosable forest—the ancient unenclosed woods—and more than sixty square miles or 40,000 acres of open heath; but at the moment no less than 8,700 acres, out of an even larger area occupied during the War for Service and other purposes, have not yet been released. The timber also suffered very heavily during the War, but there has been generally favourable comment on the smallness of the damage to the amenities by these unavoidable fellings.

Turning to the specific recommendations, it is proposed that the framework of the time-honoured administrative organisation should be maintained, authority being in the hands of the Council of Verderers, with the Court of Swainmote exercising its judicial functions, but it should be reorganised to suit it better to modern requirements. A strong case is made out for constituting the whole Forest area into a single rural district committee, which with the Borough Committee of Lymington should be the planning authority for the Forest.

In the 'inclosures', natural regeneration and group planting should be preferred to large-scale plantations, broad-leaved species favoured, and the coniferous blocks duly screened. The Committee thinks it desirable that the verderers should agree with the Forestry Commission for further enclosures of up to 5,000 acres of land valueless for grazing but suitable for planting without harming the amenities. It is recognized that owing to absence of regeneration the ancient unenclosed woods are gradually dwindling; and to remedy this, powers are recommended to enclose and restock small areas not exceeding twenty acres together, throwing them open again as soon as the new trees are out of danger from grazing stock. This is considered an important matter, and the Committee would like to see not less than fifty acres dealt with annually in this way.

Various proposals are made in connexion with the commoners, aiming at clearing up points in doubt under existing legislation and at furthering their interests. A progressive step suggested as advisable and practicable is to make the whole area a 'tuberculin-tested' area.

A recommendation which is supported by various good arguments but which may not be acceptable to all concerned is the acquisition by the Forestry Commission of the adjacent commons, aggregating no less than 6,300 acres, to be controlled and administered by the verderers as part of the 'open forest'.

Scientific men will look with special interest to the recommendation for the preservation of the whole Forest as a nature reserve under the control of the verderers acting through a specially appointed qualified curator. The difficulties involved in making sure of adequate protection of flora and fauna against an unheeding public and the unscrupulous collector of rarities are squarely faced, and proposals are made for meeting them; if adopted, the necessary powers will be there, but only time will show how effectively they can be used. It is good to note that the basic necessity of habitat preservation is recognized and leads to specific warnings against extensive heath burning and against draining certain bogs: the Committee somewhat optimistically finds "nothing irreconcilable in the competing claims made on behalf of nature lovers and holiday makers".

Some further modernization of the roads, notably a modern twin trunk road across the Forest from Cadnam to Ringwood, is inevitable. The Committee has some useful suggestions as to how to do what is necessary with minimum loss of amenity, and there are sound proposals dealing with such matters as advertising.

In this review, much of interest and importance in an excellent and comprehensive report has unavoidably been passed over. It is to be hoped that the report will be widely read and carefully considered, and that helpful criticism will be made so that the new New Forest Act which should be enacted before long will be able to take into account not only the views that have been put before the Committee during its inquiry but also views it did not hear and the reactions to the conclusions it has reached.

H. G. Champion

THE STATUS OF THE PROTOZOA

By Dr. JOHN R. BAKER

Department of Zoology, University Museum, Oxford

I

The purpose of this article is to consider whether the Protozoa are to be regarded as cells and whether the animals so named form a natural group.

The Cell as a Unit

In order to decide whether a given object is or is not a cell, it is necessary to have definite ideas as to the meaning of that word. The cell is often described as a *unit*, without any adequate account being given of what is unitary in its nature. One of the most evident facts about the cell is that its characteristic component is protoplasm, the self-perpetuating and synthesizing substance of organisms. While allowing that this word has no absolutely precise meaning, we must acknowledge that there are many substances of which it can be stated with certainty that they are not protoplasm, and that such substances occur commonly between cells, but never constitute cells; while protoplasm exists in cells (and in transformed cells). These facts are generally agreed, whatever view may be taken of the cell-theory as a whole.

There is, however, nothing unitary about the idea of protoplasm. Two separate or separable masses of this substance correspond qualitatively, in virtue of their chemical composition, but need not correspond in any numerical sense. The idea that a cell is a unit, and that different cells thus correspond numerically, must be based upon the existence of something that can be counted. The most obvious objects that suggest the unitary nature of the cell are the centriole, the nucleus and the nucleolus, all of which usually occur only once in each little mass of protoplasm. The centriole, as is well known, has a tendency to divide long before cell-division, and the nucleolus is not always single; but when all these objects are in fact single, the cell is in its most characteristic unitary form.

The chromosomes provide even better evidence of the unitary state. The cell is most clearly a unit when the nucleus has originated by the telophase transformations of one *set* of chromosomes. The haploid cell is clearly a unit, and all haploid cells correspond with one another and deserve a single name. Owing, however, to the existence of sexual reproduction in organisms, there is a necessary alternation between the haploid and diploid conditions. Haploid and diploid cells are the fundamental components of most organisms; they succeed one another in regular alternation in the germ-plasm of the great majority, generation after generation. The diploid cell, from its possession of a single nucleus and other unitary characters, can indeed be regarded as a unit; but the haploid cell is the most perfectly unitary component of organisms. One could, if one wished, suggest a decreasing order of unity in cells, as one passed from haploid to diploid, triploid, tetraploid and polyploid cells of various degrees of chromosome multiplication. Since, however, no naturally occurring organism has more than two parents, and since cells usually divide when the number of chromosomes has become doubled by division, it is reasonable to make rather a sharp distinction between the haploid and diploid states on one hand, and states in which the number of chromosomes is greater than $2n$ on the other. This distinction may reasonably and conveniently be marked by restricting the word 'cell', when used without qualification, to cases where the haploid or diploid condition is realized. The phrase 'transformed cell' may be used when an object that has possessed the characters of a cell becomes so changed as no longer to possess them—as, for example, when the number of chromosomes is increased beyond the diploid condition. Under this terminology a cell would become a transformed cell if chromosome reduplication occurred within the nucleus, or the nucleus divided mitotically without cytoplasmic division; and a *Vaucheria* could be regarded as an extreme form of transformed cell. It may be remarked that the reverse change occurs when, for example, a tetraploid transformed cell becomes diploid, in the course of evolution, by differentiation of the chromosomes.

The fact that there is usually only one nucleolus in diploid cells is related to the activities of the chromosomes. A nucleolus usually begins to form at one locus only on each of only one pair of homologous chromosomes, and the two nucleoli so formed commonly fuse.

No constantly occurring cell constituent beyond those already mentioned seems to provide evidence of unitary nature. The mitochondria and the components of the Golgi apparatus are too inconstant in number to provide reliable criteria. The unitary concept of a cell has, however, been attacked by those who have laid stress on the existence of various self-perpetuating bodies within a cell and have suggested that these are the real units. These arguments have been answered by Bourne[1], who has argued, with justice, that there are no smaller particles within cells, that are to the cell as the cell is to the multicellular organism. As he says elsewhere[2], "Cells are the ultimate vital units . . . *they* are the Lebensträger, or biophors, and there are no living individuals lower than cells".

It has been suggested that the word 'cell' has practical usefulness but only vague validity, like the word 'species'. Now the invalidity of the word species is evident from the following considerations. If an evolving organism were seen by systematists at two periods of its history, geologically remote, it would necessarily be regarded as belonging to two different species (or genera or larger groups); and if every intermediate stage were known, it would be impossible to get the concurrence of systematists as to the exact stage at which the new species was to be regarded as separate from the old. No difficulty of this kind arises in connexion with the use of the word cell, as applied to many-celled organisms (except in special cases in which, for example, tetraploidy gives place to diploidy in the course of evolution, by chromosome-differentiation). The word cell can be used with a precise and valid meaning. *A mass of protoplasm, largely or completely bounded by a membrane, and containing within it a single nucleus formed by the telophase transformation of a haploid or diploid set of anaphase chromosomes, is a haploid or diploid cell.* The presence of a single nucleolus and (at the moment when the mass of protoplasm first originated by the division of a preceding one) a single centriole would be confirmatory evidence.

Unicellular Protozoa

It follows from this definition that a great number of Mastigophora, Amœbina, Heliozoa, and Sporozoa (*sensu stricto* = Telosporidia of Schaudinn) are single cells, which alternate between the diploid and haploid condition (though nuclear unaccompanied by cytoplasmic division occurs, of course, in some forms at certain stages of the life-history). In many cases the chromosome cycle is accurately known. It has, indeed, been claimed that there are structural differences showing that the supposed cells of Protozoa are not cells, and attention has been directed in particular towards the intranuclear centrosome and spindle. The centrosome is, however, by no means always intra-nuclear in Protozoa. The extra-nuclear basal granule of flagellates is generally regarded as the counterpart of a centriole. Again, the centrosomes of the trophozoite of the gregarine, *Monocystis rostrata*, are extra-nuclear, and an extra-nuclear spindle is formed between them[3]. In the terrestrial amœba, *Hartmanella klitzkei*, the centrosome is extra-nuclear, and the nuclear membrane disappears during mitosis[4]. Arndt gives a list of Protozoa in which extra-nuclear centrosomes have been described.

Many Protozoa display the characters of a cell so well that it is not easy to understand how it can be denied that they are unicellular. The question whether certain Protista may be regarded as unicellular is, indeed, a subject of dispute among zoologists only; botanists are almost unanimous in considering that this is obviously so. Among the algæ, several distinct groups are *each* represented by species that are motile holophytic single cells, by other species that are motile colourless single cells, by others again that are motile, dendroid or palmelloid colonies, and by yet others that are simple or heterotrichous filaments (see especially Fritsch[5]). If the word 'metaphyte' is to be used as the botanical equivalent of 'metazoon', then one can say that metaphytes have unquestionably arisen more than once among the algæ. A metazoon is characteristically an animal in which there is *more than one kind of somatic cell*. This is exactly the condition in heterotrichous filaments among algæ. Now the heterotrichous *Stigeoclonium* is allied to the unicellular *Chlamydomonas*, and the heterotrichous *Dinoclonium* to the unicellular *Gymnodinium*. Conditions are particularly clear in *Dinoclonium*[6]. This is a brown marine alga that spreads as a filament over other algæ, and sends out upright lateral filaments. Single cells of the main thread become modified as swarmers, which escape from their cell-walls and swim freely as typical dinoflagellates resembling *Gymnodinium*. One cannot escape the conclusion that each swarmer is a cell, with the necessary consequence that *Gymnodinium* is a cell—a fact that will be allowed by botanists, though it contradicts those zoologists who altogether deny the cellular nature of Protozoa.

From these facts it follows that the Protozoa cannot be regarded as monophyletic: they include motile representatives of algæ belonging to various groups, many members of which are clearly not Protozoa in the ordinary sense since they are multicellular, non-motile and holophytic. To take a concrete example: *Gymnodinium* is very much more closely related to *Dinoclonium* than to *Amœba*. It is therefore wrong to include *Gymnodinium* and *Amœba* in a single group (Protozoa) which excludes *Dinoclonium*. The word Protozoa is not valid in the evolutionary or true classificatory sense, though it may be used descriptively. No precise definition will cover all organisms that are regarded as Protozoa and exclude all that are not, but the following covers all the typical ones: "Organisms that are motile and/or holozoic, and in which different kinds of somatic cells do not occur"; but it is necessary to add to these such organisms as are obviously related to those that are covered by the definition, but themselves escape it. The strict definition does not cover the Amœbosporidia (= Neosporidia), in which there is a differentiation of more than one kind of somatic cells (pole-capsule cells and envelope cells).

Non-cellular Protozoa

It will be noticed that in the proposed definition, no mention is made of Protozoa being unicellular. This is because there are many Protozoa that are not cells, in the sense in which the term has been defined above (p. 549). The Radiolaria provide some of the best examples. The careful work of Borgert[7,8] on *Aulacantha scolymantha* shows that a huge number of 'chromosomes' (more than 1,600) appear at division of the 'nucleus'. Very large so-called nuclei are usual in the group. There is no question of a meiotic division of these large nuclei, with the production of gametes containing half as many chromosomes. On the contrary, both the gametes and the non-sexual isospores contain only minute fragments of the large nuclei. The process varies in the different forms, but chromatin is often cast out into the cytoplasm and small portions of the cytoplasm are nipped off round these. The process of nuclear break-up has been described in detail by Brandt[9] for *Thalassophysa pelagica*. From the central capsule, with its single, huge 'nucleus', there develop thousands of small individuals, each with many nuclei. Although the number of chromosomes in the gametes and in the nuclei of the small individuals is not known in most cases, yet it is clear that the large 'nucleus' of the feeding stage is enormously polyploid, or 'polyenergid', as Hartmann[10,11] called it. The idea of the polyenergid nucleus occurred to him when he first saw an apparently uninucleate *Thalassophysa* change into a colony of thousands of small individuals, each with several nuclei, as Brandt had previously described. It is obvious that a radiolarian, with its enormously polyploid 'nucleus', does not correspond with a diploid or haploid metazoan cell (though it may correspond with the polyploid protoplasmic masses that occur in certain tissues of certain metazoan species).

Polyploid or polyenergid 'nuclei' occur also among the Foraminifera and in *Wagnerella* among the Heliozoa. It is probable that so-called 'chromidia' are commonly the actual *nuclei* of polyenergid forms. Further, it is among polyenergid Protozoa that amitosis is generally found. Amitosis is very difficult to understand if it ever occurs in a diploid or haploid protozoan, for it would seem likely to play havoc with the gene-complex. If, however, there is in fact a very large number of nuclei in one large 'nucleus', there is no reason why exact division should be necessary. The nuclei of polyploid protoplasmic masses in Metazoa may perhaps sometimes divide amitotically in a similar way.

Wherever new nuclei are formed from chromidia or a large nucleus divides by amitosis, polyploidy is to be suspected, and a direct comparison with a diploid or haploid metazoan cell cannot be made with any confidence. Highly polyploid Protozoa may, however, be less usual than one is inclined to suppose. The largest Protozoa are the easiest to study and much the easiest to demonstrate to elementary students; and the largest Protozoa are the most likely to be polyploid and therefore the least likely to be typical of the group as a whole. It is perhaps significant that when *Amœba proteus* undergoes mitosis, a large number of chromosomes appears[12].

The Ciliophora present a problem of their own. The so-called protociliates, such as *Opalina*, are obviously multinuclear; the other members of the group possess one or more macronuclei, the exact significance of which is still obscure. The micronucleus is unquestionably diploid until meiosis occurs at the beginning of conjugation. Two or more micronuclei are present in various ciliates of different groups; but the majority have only one, and the question is whether such forms can be regarded as diploid cells. The hypothesis that seems to fit the facts best is that the macronucleus, whether obviously multiple or not, represents a polyenergid nucleus. Races of ciliates lacking the micronucleus have been bred in several species; *Oxytricha fallax* has lived through 246 generations in this condition[13]. Amicronucleate specimens present the characteristic complex structure of the species and appear to be able to perform all normal functions except endomixis and conjugation (which they sometimes attempt unsuccessfully). It must be assumed, therefore, that they possess the complete gene-complex. A normal ciliate, therefore, is at the very least triploid. Since, however, the macronucleus divides by 'amitosis', it is probably highly polyploid; otherwise serious changes in the gene-complex would result from such a rough method of division. As is well known, various ciliates may be divided mechanically, and each half or lesser portion will show that it possesses a complete gene-complex by regenerating into a normal individual. In some forms there is no distinct macronucleus, but only a mass of small granules of chromatin; each of these may perhaps represent a nucleus.

If this argument be correct, the Ciliophora must not be compared with the diploid and haploid cells of Metazoa, but rather with the polyenergid Radiolaria and other evidently polyploid Protozoa.

THE ARTIFICIAL PRODUCTION OF MESONS

By Dr. G. P. S. OCCHIALINI
AND
Dr. C. F. POWELL
University of Bristol

RECENT reports[1] from the United States announce that E. Gardner and C. M. G. Lattes have observed that mesons are generated when α-particles of great energy are allowed to fall on matter. The α-particles were produced by the 184-in. synchro-cyclotron at Berkeley, California, the mesons being detected by the photographic method. Most of the experiments have been made by the bombardment of carbon; but in similar conditions, targets of beryllium, copper and uranium yield mesons in approximately the same numbers.

The experiments show that the production of mesons becomes appreciable when the energy of the α-particles is of the order of 300 MeV., and the yield rises rapidly with increasing energy. By observing the deflexion of the mesons in the field of the cyclotron magnet, it is possible to determine the sign of the electric charge and the value of $H\rho$ of the individual particles. The momentum of a particle can thus be determined; and this quantity, taken in conjunction with its observed range in the emulsion of the photographic plate used for detection, gives a measure of its mass. The mean value so obtained is $(313 \pm 16)\, m_e$, where m_e is the mass of the electron. The authors state that in view of the large number of tracks available for measurement, it will be possible, in the near future, to reduce the errors of the determination to the order of ± 2 per cent. Up to the present, no measurements have been made of the mass of the positive mesons by this method.

A large proportion of the negative mesons which stop in the emulsion produce nuclear disintegrations with the emission of heavy charged particles. On the other hand, the positive particles, at the end of their range, produce no nuclear disintegrations, but a large fraction of them give rise to secondary mesons. These results, taken in conjunction with recent determinations of the mass of cosmic ray mesons, make it certain that at least a large proportion of the artificially produced particles are identical in type with the heavy mesons recently discovered at Bristol[2,3].

In these latter experiments, two types of heavy mesons were distinguished: σ-mesons, which produce nuclear disintegrations at the end of their range; and π-mesons, which decay with the emission of a secondary μ-meson. It was suggested that the π-mesons, and most of the σ-mesons, are respectively positive and negative particles of the same type; and, in view of their observed production during the explosive disintegration of nuclei, that they have a strong interaction with nucleons.

This view has been confirmed by Goldschmidt, King, Muirhead and Ritson[4]. These authors, working at Bristol, have determined the mass of the particles by studying the small-angle scattering which they undergo in passing through the emulsion. The value thus obtained is $(270 \pm 40)\, m_e$, for both π- and σ-mesons. Further, the quantity m_π/m_μ, the ratio of the mass of the π-meson to that of the secondary μ-meson produced by its decay, has been determined by Lattes, Occhialini and Powell[5], using the method of grain-counting. The value thus obtained is $m_\pi/m_\mu = 1{\cdot}65 \pm 0{\cdot}15$. If it is assumed that the μ-mesons are identical in type with the charged penetrating particles of the cosmic radiation, of mass $200\, m_e$, the above result corresponds to a value of $m_\pi = 330 \pm 30\, m_e$. The masses of the heavy mesons observed to be produced artificially, and of those in the cosmic radiation, are therefore equal to within the limits of error of the experiments. In view of the points of similarity in their behaviour when brought to rest in the photographic emulsion, it may be taken as established that the two classes of heavy particles, observed in the two experiments, are identical.

Experiments with heavy cosmic-ray mesons[6] have shown that the half-value period associated with the decay of these particles, τ_π, is greater than $0{\cdot}4 \times 10^{-10}$ sec. Preliminary observations indicate that the time of flight of the particles in the cyclotron experiments, assuming them to originate in the target material and to proceed to the photographic plate without suffering spontaneous decay, allows this limit to be reduced to about 10^{-9} sec. This result is consistent with the value $\tau_\pi < 2 \times 10^{-8}$ sec., deduced by Marshak and Bethe[7] from the absorption curve of the penetrating component of the cosmic radiation at great depths.

In addition to the production of heavy mesons, the Berkeley cyclotron experiments also provide evidence that light mesons, with a mass of about $200\, m_e$, are created in the bombardment of matter by α-particles of great energy. Preliminary observations suggest that some of the negative particles of this type, at the end of their range in the emulsion, also produce disintegrations.

The 184-in. cyclotron was designed and constructed with the view of generating mesons artificially; but until recently it was thought that the fast particles it produces were not sufficiently energetic for this purpose. From the point of view of meson production, an α-particle of energy 400 MeV. was considered to be approximately equivalent to four nucleons, each of energy 100 MeV.; and such a nucleon has not sufficient energy to lead to the creation of a particle of rest-mass 300 m_e. In contradiction with this view, the observations show that the generation of mesons occurs when the kinetic energy per nucleon is about 75 MeV., and indicate that the production process must be considered in relation to the α-particle as a whole.

It is pointed out by Gardner and Lattes[1] that it is possible to reconcile the observed production of mesons with the view that they are created in interactions between individual pairs of nucleons, if, following a suggestion of McMillan and Teller[6], account is taken of the internal motion of the nucleons in the colliding nuclei. Suppose the internal kinetic energy of the nucleons, in an α-particle or in a carbon nucleus, to be 25 MeV. For the production of mesons, it may be assumed that the most favourable collisions will be those in which the relative velocity of pairs of nucleons has the greatest possible value. The maximum kinetic energy available in the centre-of-mass co-ordinate system of a pair of nucleons in such a collision will then be equal to $\frac{1}{2}(\sqrt{100} + \sqrt{25} + \sqrt{25})^2 = 200$ MeV.; a value more than sufficient for the creation of a particle of mass 320 m_e. The same approach suggests that the threshold for the production of mesons by α-particles should occur at an energy of $\sim$ 300 MeV. The observations are thus consistent with the simple assumption that the mesons arise as a result of an interaction between single pairs of nucleons.

These experiments establish the possibility of investigating the properties of mesons in laboratory conditions, with localized sources of particles of high intensity. It is reasonable to suppose that they will lead to a period of rapid advance in nuclear physics, especially in the development of our knowledge of the internal motion of the nucleons, and of the forces between them which give stability to the nuclei. They represent a technical advance of decisive importance, and the progress of the investigations will be followed with great interest.

NEWS and VIEWS

Holweck Prize: Prof. Y. Rocard

THE Holweck Prize and Medal were founded in 1945 as a memorial to Fernand Holweck, director of the Curie Laboratory of the Radium Institute in Paris, and to other French physicists who met their death during the occupation of France in 1940–44. The award, made jointly by the Physical Society and the Société Française de Physique, is conferred alternately upon a French and an English physicist. This year the Prize and Medal are awarded to Prof. Yves Rocard, professor at the Sorbonne, and director of the Physics Laboratory of the École Normale Supérieure, University of Paris. During 1925–39 M. Rocard published many papers on the equation of state of gases, hydrodynamics, diffusion of light by liquids, the optics of the atmosphere, mechanics, acoustics, and the propagation of electromagnetic waves. He introduced molecular hypotheses into the equations of hydrodynamics; he rediscovered the classical equations, determined the state of the liquid in the capillary layer which separates it from the vapour, and developed the theory of surface tension. These detailed studies of the structure of liquids enabled Rocard to determine the mechanism of the diffusion of light by an exact calculation of the intermolecular field, and to give the classical theory of the Raman effect. In connexion with these investigations, he carried out a series of theoretical and experimental studies of the transparency of the atmosphere, the range of projectiles and the visibility of signals.

This period of Rocard's scientific life was followed, from 1930 until the War, by ten years of work on acoustics, the mechanics of oscillating systems, and the mechanics of fluids; he studied the stability of motion of locomotives, the possibility of self-sustained oscillations in a centrifugal pump, and the damping of vibrations in the wings of aircraft. At the beginning of the War, Rocard put his knowledge at the service of his country, especially his work on critical frequencies of self-oscillation in aircraft, and the increase of sensitivity of sound detection apparatus. During the occupation of France, he occupied his enforced leisure in compiling a book on the general dynamics of vibrations; this has been translated into English and published in the United States. At the beginning of 1943 Rocard escaped from France and joined the Free French Forces in England. He adapted British and American radar to French ships, and took part in the liberation of Corsica and the capture of Toulon.

Engineering at the National Physical Laboratory: Mr. D. G. Sopwith

MR. D. G. SOPWITH has been appointed superintendent of the Engineering Division of the National Physical Laboratory in succession to Dr. G. A. Hankins, who recently became director of mechanical engineering research in the Department of Scientific and Industrial Research. Mr. Sopwith has been on the staff of the Engineering Division of the National Physical Laboratory for about twenty years, and his main interest has been in research on engineering materials and in the application of the basic principles of elasticity to engineering design problems. Until 1938 he worked in collaboration with Dr. H. J. Gough on fatigue and corrosion fatigue of metals, and on the design of lifting gear such as crane hooks. The former work showed the effect of the atmosphere on the fatigue resistance of various metals, while the latter resulted in improved practical designs. During the War, Mr. Sopwith carried out important work on the design of gun springs, gun barrels and shells; but his most valuable contribution was on the penetration of shot into armour plate, and his work both analytically and by controlled experiment in a laboratory armour-penetration range has done much to place that hitherto empirical subject on a sounder scientific basis. Mr. Sopwith brings to his new task, not only research experience, but also a marked ability to appreciate and then simplify analytical methods so that they can be readily applied to practical problems of engineering design.

Economics at the University of Sheffield : Dr. G. P. Jones

DR. G. P. JONES, reader in economic history in the University of Sheffield, has been appointed professor of economics in the University, in succession to Prof. D. Knoop, who retires in September. Dr. Jones is no stranger to Sheffield or Sheffield people, for he has been a member of the University staff since 1926 when he was appointed lecturer in economic history, and in recognition of the distinction of his scholarship and research the University conferred upon him in 1946 the title of reader. He has been especially interested in the organisation of the building industry from medieval to early modern times, to which field he has made distinguished contributions. In addition, ever since he has been in Sheffield, Dr. Jones has been closely connected with adult education, and throughout the whole period April 1940–July 1946 he did great service to the cause of education in H.M. Forces as secretary to the Sheffield Regional Committee, under the auspices of which more than twelve thousand lectures and classes were held for members of the Army, the R.A.F. and Women's Auxiliary Forces.

Royal Geographical Society : Awards for 1948

H.M. THE KING has approved the award of the Royal Medals for 1948 of the Royal Geographical Society as follow : *Founder's Medal*, to Mr. Wilfred Thesiger, for his contributions to the geography of southern Arabia and for his recent crossings of the Southern Arabian desert, the Rub al Khali ; *Patron's Medal*, to Mr. Thomas H. Manning, of the Geodetic Survey of Canada, for his explorations and survey work in the Canadian Arctic, including the mapping of Southampton Island and the Foxe Basin shores of Baffin Island, and for his successful adaptation of Eskimo methods of travel. The Council of the Society has made the following awards : *Victoria Medal*, to Prof. Frank Debenham, professor of geography in the University of Cambridge, for his work in geographical education and for his contributions to polar geography and exploration in the Antarctic and as first director of the Scott Polar Research Institute at Cambridge. *Murchison Grant*, to Mr. Robert W. Steel, lecturer in Colonial geography at the University of Oxford, for geographical work on the West African Ashanti Social Survey, 1945–46. *Back Grant*, to Mr. Alan J. Marshall, for exploratory and scientific work as leader of the Oxford University Exploration Club Expedition to Jan Mayen Island, 1947. *Cuthbert Peek Grant*, to Dr. Donald F. Thomson, for his explorations and anthropological studies in Arnhem Land, Northern Territory, Australia. *Gill Memorial*, to Mr. William W. Williams, lecturer in geography at the University of Cambridge, for original research during the War on the determination of underwater beach gradients.

Royal Asiatic Society of Bengal : Medal Awards

THE following medal awards of the Royal Asiatic Society of Bengal were announced at the annual meeting held on February 16 : *Barclay Memorial Medal*, a biennial award for contributions to medical or biological science with reference to India, to Rai Bahadur K. C. Mehta, principal of Agra College, for his contributions to the study of "Cereal Rusts in India" ; *Joy Gobind Law Memorial Medal*, a triennial award for contributions to the study of zoology in Asia, to Dr. Lieven Ferdinand de Beaufort, professor of zoology in the University of Amsterdam and director of the Zoological Museum at Amsterdam, for his contributions to the study of "Fishes of the Indo-Australian Archipelago" ; *Paul Johannes Bruhl Memorial Medal*, a triennial award for contributions to the study of Asiatic botany, to Prof. S. R. Bose, professor of botany, Carmichael Medical College, Calcutta, for his original research on polyporin from fungi ; *Dr. Bimala Churn Law Gold Medal*, an annual award for contributions to Indological studies, to Dr. B. M. Barua, professor of Pali in the University of Calcutta, for his contributions to the study of Buddhism in India ; *Sir Jadunath Sarkar Gold Medal*, a newly instituted biennial award for contributions to Indological researches from the thirteenth century A.D. up to A.D. 1802, to Sir Panduranga S. S. Pissurlencar, for his contributions to the study of the history of the Marathas and the Deccani Muslim Powers down to the time of Tipu Sultan.

Council for 1948

THE members of Council of the Society for 1948 are as follows : *President*, Dr. W. D. West ; *Vice-Presidents*, Dr. B. C. Law, Maharajadhiraja Bahadur Sir U. C. Mahtab, Dr. M. N. Saha, Sir B. L. Mitter ; *General Secretary*, Dr. K. N. Bagchi ; *Treasurer*, K. P. Khaitan ; *Philological Secretary*, Dr. S. K. Chatterji ; *Joint Philological Secretary*, Dr. M. Ishaque ; *Natural History Secretaries*, Dr. K. Biswas (biology) and Dr. S. K. Mitra (physical sciences) ; *Anthropological Secretary*, Dr. Verrier Elwin ; *Historical and Archæological Secretary*, H. Waddington ; *Medical Secretary*, Lieut.-Colonel C. L. Pasricha ; *Library Secretary*, Dr. B. S. Guha ; *Other Members of Council*, C. C. Blagden, H. F. Bensly, Dr. A. H. M. Mohiyuddin, Sir A. H. Ghuznavi and Ramaprasad Mookerjee.

The following were elected fellows of the Society : Rao Bahadur K. V. Rangaswami Aiyangar, director of public instruction, Travancore ; Dr. B. M. Barua, professor of Pali, University of Calcutta ; Dr. F. G. Percival, of the Tata Iron and Steel Co. Prof. D. R. Bhandarkar, formerly of the University of Calcutta, was elected an honorary fellow.

Corrosion Research in Canada

THE National Research Council, Canada, has established a committee to assemble information on all aspects of corrosion and promote its dissemination. In the first instance, a survey is being made of existing Canadian facilities for the study of corrosion and means of combating its effects. It is proposed to assist Canadian universities in making studies of the fundamental chemical and electrochemical reactions that cause deterioration of metals in service, and in the training of students in the techniques of corrosion research and prevention. In the development of a programme of research in this field the committee is seeking the co-operation of all organisations and industries that are concerned in dealing with corrosion problems, and to obtain information a questionnaire has been prepared and given wide distribution.

The chairman of the new committee is Dr. R. R. Rogers, Department of Mines and Resources, and the secretary is D. Wolochow, Division of Building

Research, National Research Council, Ottawa. Other members of the Committee are: H. J. Butterill (International Nickel Co.), N. Cohen (National Research Council), R. Judge (Department of National Defence, representing the Defence Research Board), Frank D. Forward (University of British Columbia), H. P. Godard (Aluminium Laboratories, Ltd.), Lorne Sproule (Imperial Oil Ltd.), Dr. C. Y. Hopkins (National Research Council), E. T. Hurley (Canadian National Railways), H. D. Smith (Nova Scotia Research Foundation), and Frank Twining (Canadian Industries, Ltd.).

'Supermalloy': a New Magnetic Alloy

IRON-nickel alloys, containing 35–90 per cent nickel, have permeabilities very much greater than that of iron. These alloys, called 'permalloys', are especially useful commercially for transformers. The addition of one or more of the elements molybdenum, chromium and copper to permalloys has proved advantageous. 'Mumetal', which contains usually 5 per cent copper, 2 per cent chromium, 75 per cent nickel and 18 per cent iron, is perhaps the best known of the permalloys. It is used in transformers suitable for high frequencies and is notable not only for its high initial permeability (between 10,000 and 30,000) and its high electrical resistivity (60 microhm. cm.) but also for the very simple heat treatment required in its preparation. O. L. Boothby and R. M. Bozorth have described recent developments in these high-nickel alloys for use at low inductions (*J. Appl. Phys.*, **18**, 173; 1947; see also Bozorth, R. M., *Rev. Mod. Phys.*, **19**, 38; 1947). The new material 'Supermalloy' (su-perm′-al-loy), developed during the Second World War and already supplied in considerable quantities to the U.S. Navy, contains 5 per cent molybdenum and 79 per cent nickel, the remainder being mainly iron with a little manganese. The alloy is heat-treated, being maintained at 1,300° C. in pure dry hydrogen and then cooled from 600° C. to 300° C. at a critical rate. Whereas its electrical resistivity is about the same as for 'Mumetal', its initial and maximum permeabilities are many times larger, 50,000–150,000 for the initial, and 600,000–1,200,000 for the maximum, permeabilities. 'Supermalloy' can be produced in the form of very thin insulated tape, suitable for transformer cores, and it is claimed that the use of this new alloy in communication transformers permits a threefold increase in the range of frequencies transmitted, and a pulse duration three times that previously obtained.

Colchicine, its Chemical and Biological Properties

THE sessional inaugural lecture to the Chemical Society of University College, Dublin, was delivered on February 3 by Prof. J. W. Cook, regius professor of chemistry, University of Glasgow, who spoke on colchicine. Colchicum, a drug of great antiquity, is extracted from meadow saffron (*Colchicum autumnale*). It is present in all parts of the plant, especially in the seeds, which contain up to 0·75 per cent of the active principle. The poisonous nature of colchicum was known to Dioscorides; its toxic symptoms and its only therapeutic use, in the treatment of gout, are described in "The Herball", by John Gerarde, published in 1597. Colchicine, the active principle of colchicum, was isolated by Pelletier in 1820, but was not obtained pure and crystalline until 1915. Its composition and its functional groups were investigated by Zeisel, and the main features of its molecular structure were established by Windaus in 1924. Colchicine, $C_{22}H_{25}O_6N$, contains three rings, one them a trimethoxylated benzene ring, an acety amino group, and an inert carbonyl group, and it the methyl ether of an enol. Recent studies hav shown that revision of the Windaus structure necessary, and the molecular formula of a degradatio product, deaminocolchinol methyl ether, has bee established beyond doubt by Barton, Cook an Loudon (1945). The final details of structure colchicine itself still require to be settled. The mol cule probably contains at least one seven-membere carbon ring. The remarkable effect of colchicine i arresting mitosis in nuclei at the metaphase w discovered by Lits, a pupil of Dustin; it is effectiv in a dilution of 1 in 10^8, and has important biologic applications. Thus, it may be used as an index the rate of growth of tissues, and of the activity various classes of growth-stimulating hormones. A effect on plants, first studied by Havas, was show by extensive investigations of Blakeslee to result i the production of polyploidy, leading to new an improved varieties of flowers, fruits and cereals.

Insect Pests of Flour

UNDER the title of "Insect Pests of Food: Th Control of Insects in Flour Mills" (London: H.M Stationery Office. 7*s*. 6*d*. net), the Ministry of Foo has recently issued a useful 84-page practical bulleti by J. A. Freeman and E. E. Turtle. The author are, respectively, chief entomologist and chie chemist of the Infestation Control Division of th Ministry. The bulletin deals with those insects an mites that affect the flour miller: it describes th measures that can be adopted in order to preven infestation and how to control such insects shoul they manage to establish themselves. It is divide into three main sections, namely, methods of pre vention and control; life-histories of insects an mites; and infestation in the mill. The losses whic these creatures inflict on the industry may be assesse as damage to wheat; interference with productiv processes; contamination and spoiling of finishe products and loss of goodwill and trade reputation The methods of control that are described are onl those which have been examined by the Ministr and thoroughly proved in practice. It should no be inferred, however, that these methods are in an sense static. New work is continually going on, and as examples, may be mentioned that which is bein done in assessing the value of D.D.T. and of benzen hexachloride ('Gammexane') in this connexion. Th bulletin is very well illustrated by numerous hal tone plates and text-figures.

The Bird Watcher

THE company of bird watchers grows larger wit succeeding years, its ranks including a diversity o enthusiasts, from the scientific ornithologist to th schoolboy and schoolgirl recruit. It is to help thes latter that the *Daily Mail* has issued a number o booklets on Nature subjects and so on, the latest o its School Aid series being "Bird Watching" by M Stuart Smith (2*s*.). This consists of some thirty-fou pages of excellent advice on how to study birds, wit a number of admirable photographs by Mr. Eri Hosking, supplemented by equally admirable drawings by Mr. Edward Bradbury and eight colou pictures, the latter being reproductions of plates fron Gould's "Birds of Great Britain". It is wonderfu how fresh in spirit and treatment the Gould bir portraits remain, while for accuracy of feather detai they are hard to beat. With regard to the letterpress, Mr. Stuart Smith's advice on bird-watching will be very helpful to young people, especially his hints on identifying birds in the field; in short, his book is not only a good addition to the School Aid series, but is to be recommended for any boy or girl who shows an inclination for bird study.

The Caribbean Commission

THE Caribbean Commission, instituted by the Governments of France, the Netherlands, the United Kingdom and the United States, has published its first annual report (Port of Spain: Caribbean Commission. London: Crown Agents for the Colonies). From the scientific point of view its most important work is that of the Caribbean Research Council. The Commission is a consultative and advisory body fully representative of all the Colonies (islands and mainland) in the Caribbean area. Its Research Council is specially concerned with scientific, technological, social and economic problems. After its war activities, concerned largely with provision and distribution of food to the various Colonies, the Commission and its various committees are now again getting down to work. Problems of forestry, livestock, grain crops and grassland have been investigated or are under investigation. The Commission has also been concerned with the transference of West Indian agricultural labour to the United States.

Ray Society: Annual General Meeting

THE hundred and fourth annual general meeting of the Ray Society was held on March 17. It was announced that Pennant's "Tour on the Continent 1765", edited by Prof. G. R. de Beer, would be published shortly as part of the issue to members for 1947, and other volumes relating to the British fauna and flora are in active preparation, including Prof. Berrill's work on the Tunicates, Mr. Dandy's volume on British vice-counties, Messrs. Locket and Millidge's "British Spiders", the late Prof. W. M. Tattersall's monograph on the Mysidacea, and a second volume of Prof. Balfour-Browne's "British Water Beetles". The greatly increased cost of printing is likely seriously to hamper the activities of the Society, and an urgent appeal is made for new subscribers—both institutions and individuals. Prof. G. R. de Beer, Mr. A. C. Townsend and Dr. Errol White were re-elected president, honorary treasurer and honorary secretary respectively; Capt. C. Diver and Dr. W. S. Bristowe were elected vice-presidents and Dr. Malcolm Smith, Dr. John Hutchinson, Major Maxwell Knight and Dr. Ethelwynn Trewavas new members of council.

Summer School in X-Ray Crystallography

A SUMMER SCHOOL in fundamental and applied X-ray crystallography will be held in the College of Technology, Manchester, during September 6–17. The course will be conducted by Dr. H. Lipson, Dr. H. E. Buckley and other members of the staff of the University and the College of Technology. During the course emphasis will be laid upon fundamentals such as the analysis of the basic types of X-ray photograph, and enough detail will be given to enable the student to deal with more advanced types by himself ; in addition, directions of practical application will be indicated. It is hoped that, by these methods, students will have received a clear outline of the application of X-ray methods in general and that they will thus be able to assess its value to their own researches in particular. Applications to attend the course should be sent to the Director of Extra-Mural Studies, University, Manchester 13, and must be received not later than May 12.

Announcements

WE regret to announce the death of Prof. Alfred Lacroix, For.Mem.R.S., permanent secretary for thirty-four years of the Paris Academy of Sciences, on March 16, aged eighty-five; and of Prof. E. Waymouth Reid, F.R.S., professor of physiology at University College, Dundee, during 1889–1935, on March 10, aged eighty-five.

THE honorary degree of doctor of laws has been conferred by the University of Aberdeen on Sir George Thomson, professor of physics, Imperial College of Science and Technology, London; and on Major-General D. N. Wimberley, principal of University College, Dundee.

ON the occasion of the installation of Lord Halifax as chancellor of the University of Sheffield on July 2, the honorary degree of doctor of laws will be conferred on the following: The Hon. Lewis W. Douglas, Ambassador for the United States of America; Mr. Anthony Eden; Lord Addison; Admiral of the Fleet Lord Cunningham; Sir Frank Stenton, vice-chancellor of the University of Reading; Sir Henry Tizard, chairman of the Advisory Council on Scientific Policy; and Mr. Ernest S. Graham, Lord Mayor of Sheffield, 1946–47.

DR. V. PETROW, lecturer in chemistry at Queen Mary College, University of London, has been appointed chief research chemist to the British Drug Houses, Ltd., London, in succession to Dr. W. Bradley, who has accepted an invitation to the chair of colour chemistry and dyeing in the University of Leeds.

A PRELIMINARY meeting with the view of the establishment of a Scottish Society of the History of Medicine will be held in the Library of the Royal College of Surgeons, Edinburgh, on April 23, at 5 p.m. Dr. Douglas Guthrie will make a statement regarding the constitution and object of the proposed Society, and a paper by Dr. Henry J. C. Gibson on "The Early Days of Dundee Royal Infirmary" will be read. Communications should be sent to Dr. Douglas Guthrie, 21 Clarendon Crescent, Edinburgh.

THE National Research Council of Canada has established post-doctorate fellowships in pure chemistry tenable in its laboratories in Ottawa. The normal stipend will be 2,820 dollars, but may be varied depending on the qualifications of the candidate. A travelling allowance may be made. The awards are tenable for a period of one year but may be renewed for a second year. The subjects for investigation include photochemistry, radiation chemistry, spectroscopy, organic chemistry, radioactivity, ~~low-tem~~perature investigations, surface chemistry, and the properties of gases at high pressures and temperatures. Information and application forms may be obtained from the Chief Scientific Liaison Officer, Canada House, London, S.W.1.

ERRATA. In the note on the Max Planck Society in *Nature* of March 20, p. 427, the president's name should have been Prof. Erich Regener; misprints also appear in the names of Prof. Georg Schreiber and Prof. Heinrich Wieland.

LETTERS TO THE EDITORS

Distribution of Alkaline Phosphatase in the Eggs of a Sea-urchin

IN a paper presented before the Sixth International Congress of Experimental Cytology at Stockholm, 1947, J. Runnström[1] remarked : "I find it reasonable to assume that the activation of the development means the activation of a number of enzyme systems". Starting from this assumption, I have studied the distribution of alkaline phosphatase in oocytes, mature unfertilized and fertilized eggs of the sea-urchin *Paracentrotus lividus* Lm. The material was collected during the summer of 1947 at the Station Biologique, Roscoff, Finistère.

The eggs were treated according to the histochemical methods elaborated by Gomori[2,3] and by Takamatsu[4]. The substrate contained sodium glycerophosphate and calcium chloride together with veronal buffer. The *p*H of this mixture was approximately 9·4. With this method, the sites of phosphatase activity appear black.

The results obtained may be summarized as follows.

(1) *In oocytes.* The phosphatase is localized in the nucleolus and the nuclear membrane (see Fig. 1). The cortical layer is devoid of phosphatase.

(2) *In mature unfertilized eggs.* A uniform layer of granules present in the cortex gives a strong phosphatase reaction (see Fig. 2). In all probability, these are identical with the cortical granules, which contribute to the material of the fertilization membrane (cf. refs. 5, 6). The peripheral part of the nucleus also contains phosphatase.

(3) *In fertilized eggs.* The quantity of alkaline phosphatase is considerably greater than in the mature unfertilized egg. The enzyme is present in numerous granules evenly distributed throughout the cytoplasm (see Fig. 3). There is thus no particular accumulation of the enzyme in the cortical layer. The extensive activation of alkaline phosphatase following the fertilization is accomplished within a few minutes after the attachment of the spermatozoon.

There is thus a pronounced difference with respect to quantity and distribution of alkaline phosphatase in oocytes, unfertilized and fertilized eggs of *Paracentrotus lividus*. The phosphatase activity appearing in the cortex after the maturation may be one of the factors on which the fertilizability of the egg depends. The strong activation of cytoplasmic phosphatase in the fertilized egg is in harmony with the profound modifications which the proteins undergo upon fertilization (cf. ref. 1). It is tempting to suggest that the activation of the phosphatase is in some way correlated to an increased nucleic acid metabolism.

Several aspects of this work are now being continued. A more detailed report will appear elsewhere.

My sincere thanks are due to Prof. John Runnström, who suggested this subject to me, for his help and active interest.

Paracentrotus lividus LM. EGG CELLS FIXED AND STAINED BY THE GOMORI FIXATION TECHNIQUE. (1) OOCYTE, (2) MATURE UNFERTILIZED EGG, (3) FERTILIZED EGG FIXED 45 MINUTES AFTER INSEMINATION

In (1) and (2) the cells are surrounded by a coat of jelly much distorted by fixation and embedding. The cytoplasm of the oocyte and of the mature unfertilized egg is much better preserved by cold alcohol than that of the fertilized egg ; cf. the irregular contour of the latter (3). This gives supplementary evidence of the profound alteration of the cytoplasmic fabric occurring upon fertilization

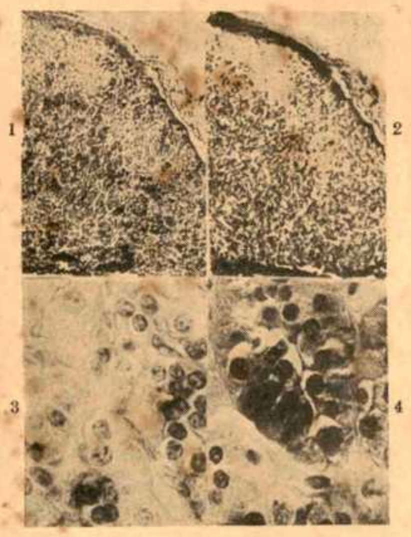
---

Alkaline Phosphatase in Various Cell Types of the Anterior Pituitary of the Guinea Pig

ONLY small amounts of alkaline phosphatase have hitherto been found in mammalian endocrines. It was, however, possible to demonstrate considerable quantities of this enzyme in the anterior pituitary lobe of both the male and the female guinea pig. After fixation of the glands in 96 per cent alcohol, in 80 per cent alcohol, in acetone or in pyridine-alcohol[1], the Gomori technique[2] was used. As already known, the nuclei of the anterior pituitary show a positive reaction which, however, has not been localized to any particular cell type[3]. In order to identify the type of cells containing the phosphatase, every two of four paraffin sections (thickness : 2–4 μ) of each gland were examined as to content of phosphatase : the two other sections were stained by Masson's trichrome (acid fuchsin, Ponceau 2*R* and aniline blue) method.

It is evident from the photomicrographs (p. 557) that the area occupied by the black product appearing subsequent to the dephosphorylation in the section is only slightly smaller than the corresponding dark area of acidophile cells in the neighbouring section of the same gland. The basophile and chromophobe cells which occupy most of the peripheral area as well as the smaller basophile and chromophobe islets within the interior area exhibit no, or very slight, enzymatic reaction.

In acidophile cells, the strongest reaction is given by nuclei and cell surface ; but in many cells the cytoplasm also shows a high phosphatase content. In such cases the enzyme is either diffusely present within the whole cell, or localized around the nuclei, or mainly concentrated in the centroplasm- (Golgi-)



PHOTOMICROGRAPHS OF FRONTAL SECTIONS OF THE CRANIO-LATERAL REGION OF THE PITUITARY OF PREGNANT FEMALE GUINEA PIG. FILTERS: TRICOLOUR GREEN AND COMPLEMENTARY BLUE

(1) Dark, alkaline phosphatase reaction area. (2) Corresponding dark area of Masson-stained acidophile cells in the neighbouring section; black connective tissue on the surface of the gland (both sections × 30). (3) Peripheral portion of phosphatase-exhibiting section; light basophile cells, dark nuclei of acidophile cells (× 400). (4) A group of acidophile cells with diverse phosphatase contents in the cytoplasm (× 400)

field, a localization found also in the intestinal epithelium[4]. The nuclei of the acidophile cells either contain large black granules or stain diffusely[3]. The highest content of enzyme was observed in the pituitary of the pregnant female. In all the glands examined a smaller number of acidophile cells was found where the phosphatase activity was confined to the nucleolus or the nuclear surface. When a group of acidophile cells in different stages of functional activity was examined, the amount of enzyme was found to vary considerably. I propose to extend the present work by following the changes of enzyme content in the different stages of secretion.

It is already clear, however, that there is no direct correlation between the enzyme content and the quantity of acidophilic granules present. The question is not yet settled whether there is a distinct qualitative (or only a quantitative) difference, so far as phosphatase activity is concerned, between the acidophile cells on one hand and the basophile and chromophobe cells on the other. Possibly the slightly blackened cells present in the light area of sections treated by Gomori's method do not correspond to basophile or chromophobe, but to acidophile cells in a stage of low phosphatase activity. It is of interest that the presence of alkaline phosphatase is correlated with the occurrence of ribose nucleic acid, the presence of which in acidophile cells of the guinea pig pituitary[5] we were able to confirm. In the hypophysis of advanced embryonic stage the phosphatase was mainly found in the nucleolus and in different parts of the nucleus, but rarely in the cytoplasm. This localization may agree with Caspersson's conception of the protein synthesis[6] in the young secretory cell as well as with observations on other secretory organs[7].

From a preliminary investigation of the hypophysis of the rat, it appears that the enzyme and the ribose nucleic acid contents are low. Our observations on operated animals lead us to believe that there is a quantitative difference between the rate of hormone production in guinea pigs and rats.

In the bovine hypophysis the acidophile cell produces the lactogenic hormone and the growth hormone, whereas the basophile cell produces the FSH, the LH and the thyrotropic hormone[8]. The same probably holds true in the case of the guinea pig (at least as regards the gonadotropic, the thyrotropic and the growth hormones)[9]. In the light of the evidence presented above, it may be inferred that the production of pure protein hormones[10] in the acidophile cell of the anterior lobe of the pituitary of the guinea pig is somehow related to high alkaline phosphatase and ribose nucleic acid content, while the production of hormones of the glycoprotein type (as well as of the adrenotropic hormone[8], which is a pure protein) in the basophile cell occur under enzymatic conditions different from those found in the acidophile cells.

Influence of Vitamin P (Vitamin C_2) upon the Amount of Ascorbic Acid in the Organs of the Guinea Pig

WE have put forward previously the view that vitamin P acts upon vitamin C as a 'sparing factor' by slowing down its oxidation; this factor should be indispensable, for without it the organism would need vitamin C in much larger quantities than can be supplied by a normal diet[1]. This theory led us to carry out two series of experiments. The first showed that various substances capable of raising the mean capillary resistance of a group of guinea pigs decrease *in vitro* oxidation of *l*-ascorbic acid[2]. The other showed that *l*-ascorbic acid, administered to guinea pigs, even in large doses and over a long period, is inefficient if the animals are given at the same time a diet deficient in an ascorbic acid economizing factor. Conversely, if vitamin P is added, *l*-ascorbic acid, even in small doses, becomes fully efficient; vitamin P alone, without ascorbic acid, has no effect. The tests used were the mean capillary resistance of a group of guinea pigs and the histological picture of the thyroid gland and of the cortico-adrenal gland[3].

It then became a question whether vitamin P would be able to increase the amount of ascorbic acid present in the organs, if the quantity of ascorbic acid administered in the diet was kept constant.

Tests were made with twenty male guinea pigs weighing about 300 gm. In a preliminary period of eleven days, the animals were given a diet with

MEAN QUANTITIES OF ASCORBIC ACID IN MGM. PER 100 GM. OF ORGAN

		I	II	III	IV
Liver	*a*	1·9	2·9 (1)	3·4 (3)	20·0
	b	4·0	<4·4	<2·6	12·3
	c	<0·6	0·9	<1·0	5·0
Spleen	*a*	3·4 (3)	3·8	6·2 (2)	18·2 (4)
	b		<2·0		12·9
	c	<3·5 (3)	1·7	<4·1	8·5
Kidney	*a*	3·8	1·4	2·0	20·3
	b	4·2	1·8	<3·4	9·5 (2)
	c	<0·8 (3)	0·6	<2·1	4·8
Adrenals	*a*	6·7 (3)	10·2	<5·3 (3)	33·5
	b				30·9
	c	<3·9	<3·9	<3·4	13·5

Diets: I—Basic diet (4 guinea pigs).
II ,, ,, + catechin*: one mgm. per animal daily, orally (2 guinea pigs).
III ,, ,, + *l*-ascorbic acid; 10 mgm. per animal six days a week, orally (5 guinea pigs).
IV ,, ,, + *l*-ascorbic acid and catechin in the doses given above (5 guinea pigs).

Techniques: *a* Direct measurement with dichlorophenolindophenol following Tillmans.
b Kinetic measurement with dichlorophenolindophenol following Meunier.
c Kinetic measurement with methylene blue following Géro.

When a measurement had not been made on all animals of a set, the number of animals which were submitted to this measurement is indicated in brackets.

* A mixture of epimers of the *d*-catechin (Percapyl Roussel).

plenty of ascorbic acid and vitamin P (cabbages *ad lib.*). Then they were divided into four sets of five animals. The diet of each set is given in the accompanying table.

The basic diet consisted of a mixture of equal weights of oats (var. *grignonnaise*, which proved, during preliminary experiments, to be without obvious effect upon capillary resistance) and bran, autoclaved at 110° C. with ammonium hydroxide for half an hour. In addition, each animal was given daily orally 1 mgm. aneurine, 0·5 mgm. riboflavine, 1 mgm. nicotamide, and twice weekly 1 cm.^{3} cod liver oil.

In groups I and II, the mean weight of the animals decreased from about the eighteenth day. It remained almost stationary in groups III and IV. In group I, one guinea pig died on the eighteenth day and two others were dying on the twenty-third day. In group II, one animal died on the eighteenth day and two others on the twenty-second day. No animals died in groups III and IV. All survivors were killed by bleeding, groups I, II and III on the twenty-third day, group IV on the twenty-sixth day. Measurements were made of the amount of ascorbic acid present in the organs of the animals which had survived until the twenty-third day.

Autopsy and histological examination demonstrated the presence of scorbutic type lesions in all animals, with the exception of those in group IV.

The measurements of ascorbic acid present were made after extraction with a saturated solution of ammonium sulphate, following the technique of Mentzer. The mean figures obtained are given in the table. Three techniques were used: (*a*) direct measurement with dichlorophenolindophenol; (*b*) kinetic measurement with dichlorophenolindophenol, following the technique of Meunier[4]; (*c*) measurement with methylene blue, following the technique of Géro[5]. It will be noted that the three techniques give rather different figures; but two points should be noted: (1) Each technique gives for the same organ amounts four to eight times larger in Group IV than in the other groups. (2) This difference cannot be ascribed to over-estimation of the amount of ascorbic acid due simply to the presence of catechin; for Géro[5] showed, and we have confirmed, that the addition of catechin either to an extract of an organ or to a pure solution of *l*-ascorbic acid does not affect the results given by Meunier's technique and even reduces those given by the methylene blue technique.

It follows from this experiment that (*a*) there is no storage of ascorbic acid when guinea pigs receive ascorbic acid without a 'sparing factor' of this substance; (*b*) catechin, alone, does not appear to alter the amount of ascorbic acid in the organs of guinea pigs which are given, during twenty-three days, a scorbutic diet; (*c*) the simultaneous supply of *l*-ascorbic acid and catechin leads to storage of a certain amount of ascorbic acid. Histochemical detection of ascorbic acid was positive only in the organs of the animals of group IV.

These observations show the manner of action of vitamin P; they explain why a higher level of storage of ascorbic acid is reached in the organs when the animals are supplied with natural sources of vitamin C than when they are supplied with pure synthetic *l*-ascorbic acid. The latter observation is in agreement with the figures published by Giroud, Leblond, Ratsimamanga and Géro[6]. More generally speaking, it seems impossible to study any action of ascorbic acid on the living organism without having determined previously the amount of the 'sparing factors' of ascorbic acid present in the diet.

In general, our work on the physiological role of this factor is in agreement with the hypothesis formerly put forward in France so early as 1926 by L. Randoin and R. Lecoq and by Bezssonoff. Bezssonoff gave the new substance the name 'factor C_2', and we think it would be advisable to return to that term. This would have the advantage of avoiding any confusion with vitamin PP, and, above all, it would recall the physiological role of this factor, which is not restricted to an effect on vascular permeability.

The Nucleolus of the Apodan Sertoli Cell

THE association of desoxyribose nucleic acid with the nucleolus has been reported in a number of different types of cells. Hydén[1] in nerve cells, Davidson[2] in the rat liver cell and Koller[3] in tumour cells, find that particles or granules giving a positive Feulgen reaction occur on the periphery of the Feulgen-negative nucleolus. Caspersson[4] has identified these granules with what he calls "nucleolus-associated chromatin". He assigns to them the important function of the secretion and deposition of nucleolar substances and a part in protein synthesis in the cytoplasm. Koller and Davidson believe that this nucleolus-associated chromatin forms an integral part of the nucleolar structure and contributes to the formation of the chromocentre and the nucleolar organisers.

Recently, while examining the Sertoli nuclei in the testis of certain Apoda (Amphibia), it was observed that the nucleolus showed Feulgen-positive granules adhering to its periphery. The nucleus of the Sertoli cell in *Siphonops annulatus* has one or more nucleoli and each of them shows a distinctly dual structure. Around the spherical nucleolus (which is Feulgen-negative) there occur a number of Feulgen-positive bodies; two to six bodies could be counted on a single nucleolus. They were larger than the granules figured by Hydén in the spinal ganglion cell of the rabbit and nearly as conspicuous as those found by Koller in the resting tumour cell treated with stilbœstrol.

The possible function of these bodies cannot yet be defined, since the function of the Sertoli cells is itself a matter of doubt in the Apoda. In these Amphibia, the Sertoli cells have undergone a great change in position as well as structure, and there is every reason to believe[5] that the usual function of providing support and nourishment to the growing sperms, assigned to the Sertoli cell of the vertebrate testis, could not hold in the case of these Amphibia. But it is a matter of great significance that unlike the tumour cell which enters on division, the Sertoli cell has no mitotic future and is to be regarded as one which has reached a stage of permanent rest[6]. In this respect the Sertoli cell resembles rather the nerve cell or the liver cell, where also mitoses are rare or wanting. It therefore appears unlikely that these granules could take part in any process associated with mitosis. The other possibility of the synthesis of cytoplasmic proteins, suggested by Caspersson, would also appear to be untenable in the Sertoli cell, where the cytoplasmic equipment is very meagre or often altogether wanting, the nucleus lying naked in the periphery of the testis locule[5]. It would therefore appear that the function of these Feulgen-positive bodies on the nucleolus is linked up with the general function of the Sertoli cell itself, which, in the Apoda, is at the moment obscure. Efforts are being made to determine these functions.

A Cytochemical Study of the Perinuclear Lipidic Layer in the Liver Cell

THE blackening by osmium tetroxide of the perinuclear layer in various animal cells is well known (see, for example, Hirschler[1]). Recently, with an electron microscope, Gessler and Fullam[2] investigated guinea pig liver fixed with osmium tetroxide and cut with the high-speed microtome; they observed that the 'nuclear membrane' is sharply shown, and that, generally, the fat-containing parts of the tissue appear darker in these electron photomicrographs.

But the blackening with osmium tetroxide is not a sufficient evidence for lipidic constitution of a structure. For this reason, I have undertaken a cytochemical study of the perinuclear layer in the liver cell.

Thin fragments of guinea pig liver are fixed in formalin or Regaud's bichromate-formalin mixture. The frozen sections are treated by different methods for cytochemical characterization of the lipids. With Sudan black, the thin perinuclear layer is stained blue-black, obvious not only on the edge, but also on the surface of the nucleus; so the presence of fats in this layer is shown. The reaction for cholesterol and its esters (Schultze's sulphuric acid–acetic anhydride method) is always negative; nevertheless, it is not possible to affirm the absence of these substances in the thin perinuclear layer, for the coloration is weak, and often not obvious in a very thin layer. The reaction for free cholesterol (Leulier–Revol's method using digitonin) is also negative. In addition, the Smith–Dietrich reaction is clearly positive, and indicates the presence of lipoids (phospholipids) in the perinuclear layer.

With the polarizing microscope, I failed to see in fresh liver cells any birefringence connected with the perinuclear lipoidic layer. In fact, observation is disturbed by the refraction of the cell substance.

The osmiophilic perinuclear layer of the liver cell contains some lipoids, just like those I previously studied in the perinuclear lipidic layer of the histiocyte[3]. Its thickness is irregular; measured on electron photomicrographs, the osmiophilic layer does not exceed 75 millimicrons, and it is much thinner in most segments. It is probably composed of a few sheets of radially ordered lipoidic molecules; each bimolecular film is about 5 millimicrons thick and located between protein layers.

Staphylokinase: an Activator of Plasma Protease

SEVERAL workers[1] have reported the lysis of fibrin clots by staphylococci, and this has been assumed to be due to a fibrinolysin produced by the bacteria.

In a series of experiments, which will be reported in detail later, twenty-seven strains of staphylococci were examined for fibrinolytic activity. All strains were first tested for coagulase, using human and rabbit plasma in parallel. Fourteen out of twenty-four strains which clotted human plasma afterwards lysed the clots which they produced. Clots were produced in rabbit plasma by twenty-three of these strains; but none of these clots showed subsequent lysis. All tubes were sealed and kept at 37° C. for one week; most of the human fibrin clots were lysed in four or five days.

The twenty-seven strains of staphylococci were then grown in digest broth, centrifuged, and the supernatant fluids dialysed under toluol against tap water for two days in the cold room. Merthiolate was added to the residues after removal from the bags. Sterile residues were shown to contain both coagulase and the fibrinolytic agent. They lysed human thrombin-fibrinogen clots in dilutions ranging as high as 1/3,000. But when either the fibrinogen or fibrin was first heated to 60° C. for half an hour to inactivate plasminogen, or when soya bean trypsin-inhibitor was added to the mixture there was no lysis.

Since soya bean trypsin-inhibitor inhibits plasmin but not bacterial proteases, it appears that the staphylococcus produces an activator of plasminogen and not a true fibrinolysin, and that its action is similar to that of streptokinase. This explains the absence of lysis with rabbit fibrin, since Christensen[2] has shown that rabbit plasma contains an inhibitor, anti-plasmin.

It is unfortunate that there has been so much confusion over terminology in this field of investigation. The plasminogen and plasmin referred to here correspond to the pro-fibrinolysin and fibrinolysin of American workers[3], and anti-plasmin to anti-fibrinolysin.

The action of staphylococci on the fibrin of other species is being investigated.

Hæmolytic System in the Blood of Malaria-infected Monkeys

THE isolation of a hæmolytic substance from normal human blood plasma has previously been reported[1]. It has so far been characterized as an unsaturated monocarboxylic fatty acid having one double bond and the possible chain-length C18. This substance has been found to be widely distributed and has been isolated in varying amounts from a large number of animal tissues, brain especially giving a high yield.

Antimalarial drugs inhibit specifically the hæmolytic activity of this fatty acid *in vitro*[2]. This fact led to the assumption that "the malaria parasites at some stage of their development produce a metabolite closely related to the naturally occurring hæmolytic substance, and that the effect of antimalarial drugs *in vivo* is bound up with their action on this metabolite". This hypothesis is now supported by further experimental data. Heavily parasitized (*Plasmodium knowlesi*) monkey blood has been examined as to its content of hæmolytic substance and has given a manifold higher yield (25–75 ×) than normal monkey blood, varying with the degree and duration of the infection. The content of hæmolytic substance in parasitized blood is increased both inside the erythrocytes, which normally contain only little, and in the plasma. Microanalysis of the hæmolytic substance isolated in crystalline form from parasitized blood was made by Dr. G. Kenner, of the Chemical Laboratory, Cambridge, and so far has shown no difference from the hæmolytic substance obtained from normal blood and other tissues.

The malaria parasites, therefore, seem to produce or cause to appear inside the erythrocytes a hæmolytic substance, possibly identical with the physiological fatty acid, which destroys the erythrocytes when its concentration is high and is then released into the plasma. The production of a hæmolytic substance by the parasites may be thought of as enabling the metabolic utilization of the constituents of the erythrocyte by the parasite and the release of the merozoites.

This mode of erythrocyte destruction by the parasite is accentuated by another parasitic metabolite, namely, the malaria pigment, which is a hæmatin compound. Hæmatin, which is not a normal breakdown product of hæmoglobin, has itself been found to be hæmolytic *in vitro* in low concentrations down to 1/50,000. In still lower, subhæmolytic concentrations (1/200,000), it strongly potentiates the effect of the hæmolytic substance. In the light of these results, it might be interesting to study the quantitative relations of these two factors in the blood of blackwater fever cases.

I am indebted to Dr. F. Hawking, of the National Institute for Medical Research, London, for providing me with the samples of monkey blood used in these experiments. A detailed report will appear elsewhere.

Nitrogen Metabolism After Fracture

AFTER a severe injury, such as a fracture, nitrogen balance usually becomes negative and the body loses nitrogen. The extent to which local effects of the injury (damage to tissues and disuse atrophy of muscles) contribute to this outpouring of nitrogen appears to have received little attention. The only direct measurements of loss of tissue from fractured limbs are those of Cuthbertson, McGirr and Robertson[1], who studied rats. These investigators fractured one femur of each rat, and on the tenth day after injury the animals were killed and both hind limbs were weighed. The average difference in weight between the sound limb and the injured limb was 1·03 gm. Assuming the material lost from the injured limb to have been muscle, they calculated that this difference in weight was equivalent to a loss of 32·2 mgm. nitrogen. There was, however, an average excess output of 425 mgm. nitrogen in the urine during the first nine days after fracture. From these observations it would seem that very little of the excess nitrogen excreted after fracture comes from the tissues of the injured limb.

We thought it desirable to repeat these experiments with certain modifications: first, the animals were killed five or six days after fracture, because it was thought that by the tenth day reparative processes may have partly compensated for earlier loss of tissue; secondly, direct determinations were made of the nitrogen lost from the injured limb, rather than indirectly by weighings of tissue. Two groups of rats receiving a 25 per cent casein diet were used, and the urinary collections and fracture technique were similar to those employed in previous experiments[2]. The first group of rats were killed five days after fracture, the second group six days after fracture. By this time the main phase of increased nitrogen excretion was ended in each group. The hind limbs were skinned and dissected from the trunk, using anatomical landmarks in order to achieve symmetrical removal of right and left limbs. After weighing, each limb was digested in concen-

Group of rats	No. in group	Mean body-weight (gm.)	Mean difference between right- and left-hind limbs		Mean excess output of N in urine during post-fracture period (mgm.)
			Weight (gm.)	N (mgm.)	
I	6	346	0·68 (= 21·3 mgm. N*)	60·3	205·7
II	5	166	0·16 (= 5·0 mgm. N*)	11·2	128·4

* Calculated from 1 gm. rat muscle = 31·3 mgm. N (Cuthbertson *et al.*[1]).

trated sulphuric acid, and nitrogen determinations were made on aliquots. As indicated in the accompanying table, the mean differences in weight between the injured and uninjured limbs were smaller than the mean difference found by Cuthbertson *et al.*[1]; but differences in the nitrogen content of the limbs found by actual analysis were greater than nitrogen losses calculated on the basis of differences in weight. The nitrogen lost from the injured limb did not, however, account for more than a small proportion of the extra output of nitrogen in the urine after the injury. These observations accordingly confirm the view put forward by Cuthbertson[3] that the greater part of the nitrogen lost from the body after an injury comes from sources other than the injured limb.

Effect of Colchicine Treatment on the Alkaloidal Content of *Datura metel*

As a result of the work of Rowson[1], who found that the induced polyploids of various Solanaceous plants possessed higher alkaloidal contents than the normal varieties, we have investigated during the past two years the effect of colchicine treatment on the alkaloidal content of *Datura metel*, a commercial source of hyoscine.

A batch of seeds of *Datura metel* was well mixed and divided into two equal portions, one of which was treated with 0·4 per cent aqueous colchicine solution, as described by Rowson[1]. During March 1946 the seeds were sown in boxes and the plants reared under glass until about six inches high, when they were planted in the open on the materia medica farm at Dartford. The treated and the untreated plants were placed in separate plots but, so far as was practicable, under identical growing conditions. At the beginning of November 1946, the plants were harvested and a representative sample of each type assayed. The experiment was repeated in 1947 and the analytical results for the whole investigation are summarized below.

	1946		1947	
	Untreated	Colchicine-treated	Untreated	Colchicine-treated
Total alkaloidal content (%) expressed as hyoscyamine, calculated with respect to the plant in 60-mesh powder dried at 100° C.	0·422	0·419	0·401	0·438

These figures do not seem to us to support the view that colchicine treatment of the seeds results in a significant increase in the alkaloidal content of the plants; but in so far as we were unable to obtain any evidence of polyploidy by microscopical examination of our treated plants, it appears that in our experiments we were unsuccessful in producing polyploid species of *Datura metel*. We think that our results should be recorded, however, for the benefit of other workers interested in the practical applications of polyploidy.

Structure of Yeast Ribonucleic Acid

DURING recent years, facts have accumulated about the electrometric titration of samples of yeast ribonucleic acid isolated by various methods. All the titration curves published[1-6] show on analysis the presence of a group titrating in the range *p*H 5·0–8·0; further, the pentose nucleic acid of the larvæ of *Calliphora erythrocephala* exhibits a similar dissociation[7]. The amount of this group present varies slightly with the samples used by different observers, but is generally of the order of 0·7 equiv. per statistical tetranucleotide in the polynucleotide, and it has been shown by Fletcher, Gulland and Jordan[3] that this value approaches close to 1·0 equiv. per four atoms of phosphorus on correction for the phosphorus-deficiency commonly encountered in this nucleic acid. There appears to us to be no reason to suppose that the simplest interpretation of this observation is not the correct one, namely, that the group is a secondary phosphoric acid group; this conclusion was reached by Fletcher, Gulland and Jordan[3] and by Chantrenne[4]. The suggestion put forward by Allen and Eiler[2] that this group is a very weak primary phosphoric acid group could only be accounted for on the basis of a much greater disturbance of the interrelationships of the groups in the polynucleotide than has so far been contemplated.

Any proposed structure for yeast ribonucleic acid must take into account the evidence derived from titration, which demands the presence of three primary and one secondary phosphoric acid groups, three amino-groups and two purine-pyrimidine 'hydroxyl' groups for every four (corrected) atoms of phosphorus in the polynucleotide. The simplest formulæ on this basis are those proposed by Fletcher, Gulland and Jordan[3], which are based also on the assumption that the phospho-ester linkage is the main internucleotide bond. At least one other formula which involves pyrophosphate groups and ether linkages satisfies the titration data, but is not acceptable on stereochemical, and perhaps chemical, grounds.

The experimental results of Zittle[5] on the enzymatic degradation of yeast ribonucleic acid, which are considered by him to invalidate the formulæ of Fletcher, Gulland and Jordan[3], cannot at the moment be explained, particularly in view of the facts that, on our analysis, the electrometric titration curve of his nucleic acid initially showed 0·7 equiv. of a secondary phosphoric acid group per tetranucleotide, and that enzymic degradation liberated 3·45 additional equivalents of a secondary phosphoric acid group, as stated by him. The total number of such groups is thus 4·15, the maximum possible being 4 on the basis of any structure for a polynucleotide with the correct theoretical phosphorus analysis. The sample titrated by Zittle would have had to contain about 28 per cent of its weight of water for its phosphorus content to have agreed with the theoretical value; and since this figure is much greater than that normally found, it follows that the phosphorus content was low and that the maximum possible number of secondary phosphoric acid groups must in this case have been less than 4; thus the total of 4·15 equivalents, found experimentally by titration, must have been even more divergent from that theoretically possible in this instance than is at first apparent. We do not consider that the evidence presented by Zittle is at present sufficient to override the considerable weight of experimental fact which is in favour of the formulæ of Fletcher, Gulland and Jordan.

Adsorption of Calcium Ions by an Acid-extracted Brown Alga under Continuous Flow Conditions

The interaction of simple ions with plant cells has been frequently studied, and it has been found that in some cases cations and anions are both absorbed in the vacuoles[1], while under different conditions the readjustment of the salt content occurs mainly by ion exchange[2]. The experiments now to be described belong to the latter type; but, so far as I am aware, this is the first time that the ionic adsorption by a plant material has been systematically studied under flow conditions comparable to those prevailing in inorganic chromatographic adsorption analysis.

The measurements were done with the brown alga *Ascophyllum nodosum* and with solutions containing calcium ions. The fully swollen well-washed algal material, in which the majority of the cells appeared to be dead, was prepared from particles varying between 5 and 50 mesh/inch, and had been extracted with 1 N hydrochloric acid, at 20°, for about half an hour, thereby exchanging the various metals in the cell tissue against hydrogen ions[3]. The ionic adsorption is characterized by the break-through capacity, α, the number of equivalents of calcium adsorbed until the calcium can just be detected in the effluent; by the half saturation value, β, the equivalents of calcium adsorbed until the calcium concentration in the effluent is one half of that of the original solution; and by the exchange ratio, γ, the equivalents of acid in the effluent per one equivalent adsorbed calcium. The α- and β-values were not detectably influenced by illumination or by the oxygen content of the solution, but they depend on the history, age and particle size of the adsorbent and on the rate of flow, acidity and concentration of the solution. The exchange ratios, γ, were found to be near unity, which indicates that the uptake of calcium ions depends mainly on a conversion of the water-insoluble acids contained in the cell tissue into the relevant calcium salts, which are also water insoluble. The algal material used for these tests contained 2·8 gm.-equivalents of such acids per kgm. dry weight[3]. In most runs the α- and β-values were much smaller than 2·8; that is, the calcium ions appear in the effluent before the absorbent is fully neutralized. If, however, the *p*H value of the solution is relatively high, the break-through capacity approaches the neutralization equivalent, and under such conditions the adsorption capacity of this alga is similar to that of certain recognized cation-exchange materials.

A detailed account of these experiments is to be published elsewhere.

Ferromagnetic Structure of Cold-Worked Austenitic Stainless Steels

In magnetic wire recording, the medium most frequently used for the recording of music is chromium-nickel austenitic stainless steel, which has been rendered ferromagnetic by drawing into fine wire. By suitable heat treatment after drawing, it has been found possible to obtain intrinsic coercivities $({}_IH_c)$ as high as 500 oersteds, a value so far in excess of the normal range for steels that some explanation seems required.

From the recording characteristics briefly described below, we have been led towards the idea of a dispersion of ferrite particles, probably long in relation to their cross-section, and of individual volumes of the order of a single domain, in a non-magnetic matrix of austenite. Support to this conception is given by the well-known results of the X-ray study of face-centred cubic structures[1] such as austenite, and the probability that the ferrite is produced along the slip planes of cold work; by the evidence both of magnetic testing and of X-ray examination that hard-drawn wires consist of some 50 per cent ferrite and the best heat-treated wires of only about 10 per cent; by the similarity between the variations of remanence with heat treatment for these wires and those for non-magnetic substances containing ferromagnetic impurities[2]; and by the close resemblance between the recording performance of these wires and that of magnetic tapes in which the medium consists of fine ferromagnetic particles embedded in a non-magnetic adhesive. A series of notes by Néel[3] have put forward an explanation of the high coercivities found in powders of cubic ferromagnetics and certain alloys on the assumption of inclusions of magnetic substances of extremely small dimensions in a non-magnetic matrix, and the recent important communication by Prof E. C. Stoner and E. P. Wohlfarth[4], on the interpretation of high coercivities in ferromagnetics provides a general picture into which our conclusions, developed from quite another starting point, fit very well.

Very briefly, the development is as follows. To produce a sine wave, the changes in magnetization must occur in many small, rather than a few large, steps; the ferrite must therefore be relatively evenly distributed in the wire. The ratio of maximum (undistorted, hence wire not saturated) signal strength to minimum (undistorted, although superposed on the minute variations causing the almost inaudible background noise) is of the order of 1,000 to 1, which represents the ratio of the number of particles undergoing reversals of direction of magnetization; the total number of particles in the cross-section of the wire is probably therefore of the order of 10^5–10^6. For a wire of standard diameter (0·004 in. = 10^{-2} cm.) containing 10 per cent ferrite, the mean diameter of a single particle would therefore be between $3 \cdot 2 \times 10^{-6}$ and 10^{-5} cm., so that a number might well be less than the critical value (300 A. for iron spheres given by Néel, and of the same order by Stoner and Wohlfarth) below which single domain formation is energetically possible. Again, the length of a particle must be of the order of half the wavelength of the highest recordable frequency; at 2 ft./sec. with the high-coercivity wires, frequencies of 70 kc./s. can be recorded, and probably very much higher. Taking 100 kc./s. as the maximum, the length would be $3 \cdot 05 \times 10^{-4}$ cm., but it is quite probable that this frequency is too low and that the mean particle-length is less. These tentative values suggest particles of a cylindrical or prolate ellipsoid shape and of single-domain dimensions.

It is hoped to develop more fully elsewhere the method of approach outlined above.

Effect of the Electron Beam on the Voltage Distribution of a High-Voltage Multi-Stage Electron Accelerator

During the course of experiments on electrostatic focusing with a multi-stage accelerating tube[1], and afterwards with a multi-stage X-ray tube, it has been observed that the electron beam acts as if it were a potential divider (not necessarily uniform) connected to the accelerating electrodes.

In the early experiments, when attempts were made to control the potentials of the accelerating electrodes by means of corona points, the voltage distribution was found to vary with the beam current. Unless the corona current was equal to, or in excess of, the beam current, the potential distribution was controlled mainly by the beam current. These results were repeated using a potential divider in place of the corona points, and the effect observed at voltages up to 300 kV. D.C. using two, three and four stages of acceleration.

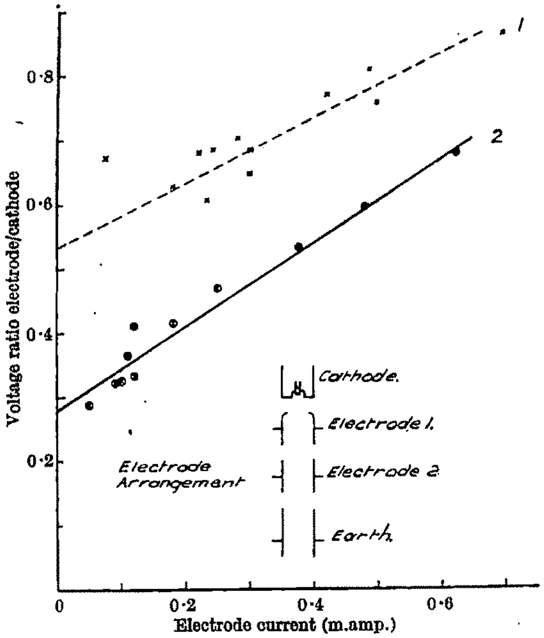

Fig. 1. RATIO OF VOLTAGE ON ELECTRODES (1 and 2) TO VOLTAGE ON CATHODE AS A FUNCTION OF CURRENT FLOWING TO ELECTRODE – CATHODE CURRENT KEPT CONSTANT AT 10 m.amp.

Later experiments were carried out on a three-stage X-ray tube fed from three high-voltage transformers in cascade, and the voltage of each stage in the cascade could be varied independently. The electrode arrangement is shown in the inset in Fig. 1; the currents were measured by milliammeters inserted in the leads to the electrodes, and the voltages by potential dividers.

Experiments were carried out varying the stage voltage ratios, and the corresponding D.C. currents to the electrodes observed. Some of the results are recorded in Fig. 1, from which it will be seen that at some particular ratio of voltages the current to the electrodes approached zero. It is of interest to note that with the particular electrode formation used, the voltage across the upper stage was greater than one third of the total voltage at zero electrode current. The manner in which the gradient varies with the electrode currents is clearly illustrated in Fig. 2, with a beam current of 10 m.amp.

From these results it was concluded that the electrodes would acquire the potential distribution indicated by the voltage ratios at zero electrode current in Figs. 1 and 2 if allowed to float and to

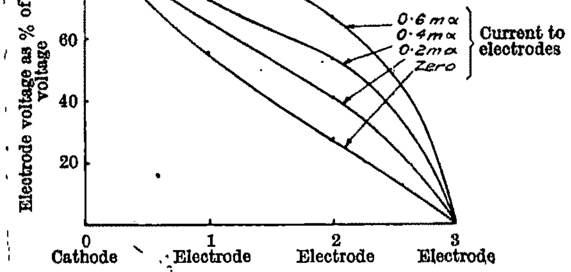

Fig. 2

depend for their source of potential solely on the beam of electrons flowing down the accelerating tube. That this conclusion was correct was confirmed afterwards by running the accelerating tube from a D.C. source and measuring the electrode voltages by means of a spark gap and later by an electrostatic voltmeter. These experiments indicate that a resistance divider will not exercise much control over the potentials of the accelerating electrodes of a multistage tube unless the current flowing in the divider is equal to, but preferably greater than, the beam current. The results are of particular interest in the case of electrostatic generators of low power, where a resistance divider passing only a fraction of the full beam current is used, presumably to obtain uniform voltage grading of the electrodes of the accelerating tube.

The exact mechanism by which the electron beam charges or discharges the accelerating electrodes has not been established; but it would appear that electrons from the main beam strike the electrodes and possibly release secondaries which tend to make the potential of the electrode more positive. This alters the voltage ratio of the stage, and so alters the focusing of the electron beam that fewer electrons strike the electrodes and the potential has a negative tendency. Thus it is conceivable that the electrodes will achieve a stable potential.

From this argument it would appear that the stage potentials are related to the beam focus, and the possibility arises of controlling the voltage distribution by modifying the shapes of the accelerating electrodes. Whether the shape required for satisfactory voltage distribution would also give a suitable focus is a matter for experiment. With multistage tubes, however, the electrode shapes are fortunately of secondary importance compared with the ratio of the voltage across the cathode to first stage to the total voltage, and so some latitude in the electrode shape from the focusing point of view is possible.

The possibility also arises of potential control by suitable choice of metals for the electrode construction, as the number of secondary electrons produced by primary bombardment varies for different materials.

It is suggested that to obtain uniform voltage distribution under all conditions in a multi-stage accelerator the electrodes should be developed on the lines suggested to give uniform voltage distribution with the electrodes floating; and a resistance divider such as is used at present should be incorporated to control the potentials at very small beam currents (that is, with a cold cathode).

Apparent Emission of Positive Electrons from β-Emitters

SEVERAL investigators have reported finding positive particles emitted from β-emitters[1-8], in numbers very much greater than allowed by the theory of pair production either by γ-rays or β-particles. In some cases positive particles have been found to the extent of 1 per cent of the β-radiations from substances which are not γ-emitters[4,7]; and in others positive particles of surprisingly high energy have been detected[7].

It has been suggested that the theory of pair production is wrong by a considerable factor; but an extensive investigation by Crane and Halpern[9] found no disagreement between theory and experiment. Again, experiments using β-ray spectrographs have failed to confirm the existence of the supposed positive particles in anything like the numbers found in the cloud chamber. Two recent experiments[10,11], one in this Laboratory, have confirmed this result and shown that less than one positron is present in 75,000 β-particles. In addition, a search has been made for the annihilation radiation which positrons might be expected to produce, and none has been found[12].

In an attempt to resolve the discrepancy between results obtained with the cloud chamber and with other methods, a number of photographs of tracks from radium E and radium (D+E) have been taken. Radium E provides a suitable case for test because its γ-radiation has insufficient quantum energy to produce electron pairs. For the first series of photographs, radium E was deposited on a nickel wire which was placed at the centre of the chamber and along its axis. No slit system was used. The chamber had a diameter of 15 in. and was filled with air at 43 cm. mercury initial pressure. A magnetic field of 600 gauss was applied. Photographs of 316 tracks were obtained, and among them were eight which, from their direction of curvature and the increase of curvature along their length, appeared to be positrons.

In other experiments, a strong source of radium (D+E) was placed in a collimated holder with a magnetically operated shutter, so that a narrow beam of particles was obtained. The source was somewhat below the centre of the chamber. With this arrangement, more than two thousand tracks were observed, but to only two of these was it possible to ascribe a positive curvature.

Finally, some photographs were taken with the first arrangement of source but without a magnetic field, in order to observe the effect of multiple scattering on the shape of the β-ray tracks. In the forty-nine tracks which were obtained, the majority were fairly straight, some had an *S*-shape, while sixteen showed a measurable curvature in the same direction similar in appearance to a curvature due to a magnetic field. The results were in general agreement with Bethe's calculations[13] on multiple scattering. Using his formula, it can be shown that β-rays of energy less than 100 keV. will give tracks in air at atmospheric pressure with an average apparent radius of curvature due to multiple scattering of the same order as the curvature due to a magnetic field of 300 gauss; the magnetic fields used in the experiments quoted above varied between 230 and 500 gauss.

In the light of the last two series of photographs and of Bethe's theory, it would appear, therefore, that the apparently positive tracks observed both in the first part of this experiment and in the work of others, cited above, can be explained in either of two ways. In some cases, they would appear to be β-rays which have travelled full circle and the tracks of which show an increase of curvature in the sense to be expected for positive particles because of the effects of multiple scattering; the great majority of the particles which have been observed would fall into this class. In other cases, they would appear to be β-rays, sometimes of low energy, the tracks of which show the curvature of a positive particle because the multiple scattering has counterbalanced the curvature due to the magnetic field; such an effect would explain the observation of apparently positive particles with an anomalously high energy.

Relation Between Photoconduction and Luminescence in Zinc Sulphide

A LARGE part of the studies on the afterglow or phosphorescence of solids has been made on zinc sulphide activated by copper (ZnS–Cu). Most of the theories of phosphorescence of ZnS–Cu have been based on the assumption that, when light is absorbed by the phosphor, electrons are freed from the luminescence centres and wander about the crystal. These free electrons may then be captured by traps, where they may spend appreciable time before they are freed by thermal energy, and may, then, either be retrapped, or are recaptured directly by empty luminescence centres, thus producing luminescence. The time the electron spends in the trap corresponds to the time delay of emission in phosphorescence.

We wish, however, to direct attention to experimental evidence which indicates that traps and luminescence centres co-exist in one centre, and that each excited electron is raised to a trap-level in this centre and may not be free to travel through the crystal. This evidence is based on two simple experiments. In the first experiment the phosphor is heated to empty all traps, cooled in the dark to 90° K., and then illuminated by exciting light. On warming the phosphor in the dark, electrons escape from traps and produce thermoluminescence and, as the temperature is raised steadily, the resulting thermoluminescence is produced by electrons from traps of progressively greater depth. The curve of thermoluminescence intensity plotted against temperature is the glow curve of Randall and Wilkins[1]. If the phosphor is excited by a sufficiently small amount of light energy, only a small fraction of the traps is filled and, hence, if the electrons escaping from traps wandered through the crystal, the chance of an electron being retrapped would be very great. It may be shown that, as a result, the ratio of the height of the glow curve at high temperatures to that at low temperature would be much greater for the case of partly filled traps than for completely filled traps. The significant fact is that for ZnS–Cu this ratio is only slightly different for the two glow curves (Fig. 1), there being appreciable emission at 200° K. for curve *b* in spite of the fact that only 0·1 per cent of the traps in the phosphor were filled by exciting light.

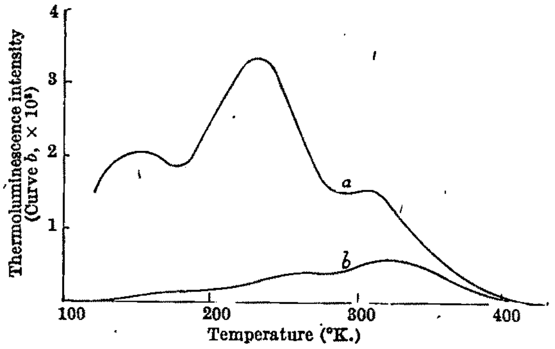

Fig. 1. THERMAL GLOW CURVES FOR A COPPER-ACTIVATED ZINC SULPHIDE PHOSPHOR (WURTZITE) FOR DIFFERENT EXCITATION CONDITIONS

(*a*) Strongly excited at 90° K.; (*b*) weak excitation at 90° K. Area under curve *a* (that is, number of filled traps) is 1,300 times area under curve *b*

This lack of retrapping might be explained in two ways: either the traps are in the luminescence centres, or they are separate and there exists a large number of empty luminescence centres in the unexcited phosphor. The latter explanation is ruled out by the second experiment, which shows that when the phosphor with all traps empty is excited at any temperature from 350° to 90° K. by constant low illumination, the intensity of luminescence increases slowly from zero. If there were empty luminescence centres in the unexcited phosphor, the electrons liberated from luminescence centres would, to some extent, be captured directly by the empty centres, and there would be a sudden initial rise of luminescence. Moreover, when the phosphor has been exposed to previous illumination at high temperature so that some very deep traps are filled, empty luminescence centres must exist in the phosphor. When the phosphor in this condition is exposed to exciting light at room temperature, the luminescence intensity again rises slowly from zero, though more rapidly than if all the traps had been previously emptied. Therefore, it does not appear that an electron from one luminescence centre can pass

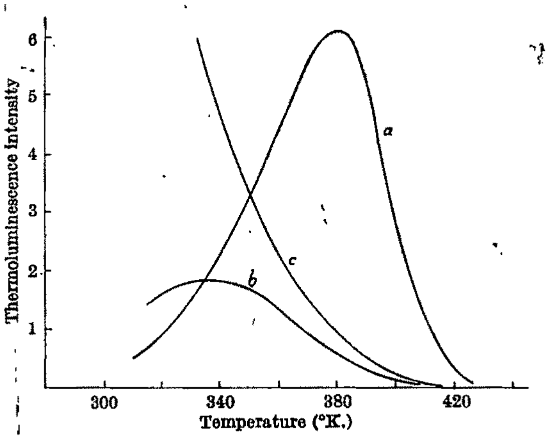

Fig. 2. THERMAL GLOW CURVES FOR A COPPER-ACTIVATED ZINC SULPHIDE PHOSPHOR (WURTZITE) FOR DIFFERENT EXCITATION CONDITIONS

(*a*) Strongly excited at 370° K. and then cooled to 295° K.; (*b*) excited by small amount of light at 295° K.; (*c*) excited by large amount of light at 295° K. (curve reduced in height) directly to another empty luminescence centre, and one is driven to the conclusion that a large part of the luminescence of ZnS–Cu does not involve electrons travelling freely through the crystal. The photoconductivity of ZnS–Cu may be simply due to a limited displacement of the electrons within the trap and luminescence centre.

Finally, we would like to answer a possible criticism of the work of Randall and Wilkins (*loc. cit.*), who maintain that there is continuous distribution of trap-levels in such phosphors as ZnS–Cu. It has been correctly pointed out that some of the glow curves in these papers, quoted as evidence for a continuous trap distribution, could be explained on the basis of a single trap-level if retrapping is taken into account. This theory would require, however, that the shape of the glow curve should be a function only of the number of traps filled. This is not the case, however, and the glow curves in Fig. 2 show the quite different curves obtained if the traps are partly filled by strong excitation at a high temperature (the phosphor being afterwards cooled in the dark) or by feeble excitation at a low temperature. These results seem to show conclusively that the trap-levels are distributed in depth.

We hope to publish shortly further details of this work.

Ozone and Auroral Spectra

IN 1941, we published a theory[1] which provided, among other things, an explanation of seasonal and latitude variations in the thickness of atmospheric ozone. From this theory we were able to predict ozone thicknesses in latitudes for which, as yet, there are no direct observations—for example, in polar regions. Furthermore, we have shown that near the poles the ozone thickness should be practically zero soon after the winter solstice.

Now routine measurements of ozone thickness, carried out by E. Tönsberg and K. L. Olsen in Tromsö[2], have shown values so low as 0·05 cm. in December. It may be assumed that these occurrences are due to the movement of air masses from higher latitudes, so that the results afford good confirmation of our theoretical predictions.

When so little ozone is present, opportunities are offered for making spectrographic observations, as, for example, by observing the trans-auroral line 2972 A. ($^3P_1 - {}^1S_0$), O I. For this wave-length the optical density of the atmosphere is 0·60 (due to molecular scattering) and 0·365 (due to absorption by ozone), so that the intensity of radiation reaching the ground is about a tenth of that in the upper atmosphere. According to Pasternack's transition probabilities[3] and to the experimental confirmation by L. and R. Herman[4], we must expect a greater intensity for the line 2972 A. than for the line 6300 A. ($^3P_2 - {}^1D_2$), so that even allowing for a reduction of intensity of a tenth, the trans-auroral line should be observable in a zenithal aurora, in Tromsö, during a winter night when the ozone thickness does not exceed 0·05 cm.

Of course, this observation should be easier at a higher latitude, for example, in Spitsbergen, and preferably at some altitude above sea-level, in order to reduce molecular scattering. It is also to be expected that at other stations, at the same or even a lower latitude than Tromsö, the existence of polar air flows might offer still more favourable observing conditions.

It may be added that considerations of atmospheric absorption indicate that, under similar conditions, it might be possible to extend, by at least 200 A., the observed spectra of stars suitably located.

Mass-Spectrographic Separation of Isotopes of Gaseous Elements

EXPERIMENTS recently carried out in this Institute[1] have shown that, by bombarding silver disks with beams of ions of neon isotopes obtained from a high-intensity mass-spectrograph[2,3], it is possible to prepare targets, containing the separated neon isotopes, that are suitable for certain investigations in nuclear physics. Due to the high energy of 60 keV., the ions penetrate into the silver surface to a depth of about one hundred atomic diameters, and to this depth a high concentration of neon atoms can be obtained. The experimental results (*loc. cit.*) indicate that a maximum concentration is approached when the surface has been hit by about 6×10^{16} ions per cm.^{2}, corresponding to the collection of 2 μgm. of neon per cm.^{2}, if all the neon atoms remain in the surface.

In the meantime, it has been demonstrated that it is possible to release the neon atoms almost completely from the silver by heating the target materia by means of high-frequency induction *in vacuo*. I a sufficiently large target area has been irradiate with neon ions, it is possible in this manner to isolat quantities of neon gas, containing one isotope only sufficient for many experimental purposes. Experiments of this kind have also been carried ou with aluminium, nickel and tungsten as targe materials.

The experiments were carried out in the followin way. The targets, 6·0 cm. × 2·5 cm. in size, wer cleaned by means of a suitable acid, rinsed wit distilled water and then strongly degassed by high frequency induction *in vacuo*. After a target ha been mounted in the mass-spectrograph, its surfac was exposed, a portion at a time, to the bombardment of $^{20}Ne^+$-ions at a current of about 40 μamp. for about one hour altogether, so that maximun concentration of neon atoms in the entire surfac would be ensured. Then the target was remove from the apparatus and rolled around a steel cylinde of 6 mm. diameter, in order to give it a shape appro priate for installation as an electrode in a Geissler tube. Each tube contained one neon-irradiated electrode and one untreated nickel electrode, and had a volume of about 30 cm.[3]. Moreover, each tube was provided with a small trap filled with charcoal for the absorption of small amounts of impurities which could not be entirely avoided when preparing the tubes. After the tube was evacuated, the nickel electrode and the charcoal trap were thoroughly degassed, and when the pressure had been reduced to about 10^{-5} mm. of mercury, the tube was sealed from the pump. Then the irradiated target was heated by high-frequency induction, and at a glowing red temperature the neon atoms were rapidly released from the target surface, raising the pressure in the tube to about 0·5 mm. mercury.

A spectroscopic analysis of the light emitted from the Geissler tubes showed extremely clean neon spectra. In some cases one could observe very small impurities of hydrogen and carbon monoxide which, however, could be greatly reduced by cooling the traps. In order to provide an experimental control on the amount of impurities, Geissler tubes were prepared with aluminium, nickel, silver and tungsten electrodes which had been treated in the same way as described above and installed in the mass-spectrograph, but not exposed to the beam. Immediately after heating these electrodes the tubes were capable of being ignited; but after a few minutes the impurities were absorbed in the traps and the pressure thereby reduced so that the tubes were extinguished, indicating that the pressure was less than 5×10^{-3} mm. mercury. As expected, neon lines were not observed from such tubes.

In order to determine the influence of the ionic mass on the ease of collecting a gas in a metal surface by the method described above, similar experiments were carried out with helium, argon and xenon. By bombarding a silver target with He^+ ions, a Geissler tube was prepared containing extremely pure helium gas at about the same pressure as previously found in the experiments with neon. Similar results were obtained by bombarding aluminium targets with beams of argon and xenon ions. As the experiments with xenon were carried out only to test the possibility of collecting this gas in the target surface, no separation of the xenon isotopes was carried out.

If a mass-spectrograph is to be used in this manner to prepare pure samples of the less abundant isotopes of the rare gases, more favourable experimental conditions will be obtained if substances already subjected to a partial isotopic separation by other methods are used as starting materials. Recently, a method for the separation of the isotopes ^3He and ^4He has been suggested by J. Franck[4], and preliminary experiments based on this suggestion have already been carried out[5,6]. If the application of this method proves to be successful for the separation of strongly enriched samples of ^3He, it may be possible to prepare pure ^3He gas by the mass-spectrographic method described above.

It seems likely that the mass-spectrographic method of separating isotopes of gaseous elements, which has been demonstrated in connexion with the rare gases, may be extended to other gases if suitable target materials are used. The power of metals to absorb gases to some extent, when they are hit by ions of high energy, is well known from the studies of gaseous discharges[7]; but exact measurements of the conditions under which this absorption takes place cannot be carried out by this means, as it is difficult to obtain well-defined experimental conditions. The technique described here, however, offers the possibility of a closer study of the amounts of gases that can be collected in the surface of different target materials at definite energies of the impinging ions. From theoretical arguments[8] it seems likely that the range of the ions in the target material will increase in direct proportion to the ion energy, and the amounts to be collected will presumably increase in the same proportion. It appears that the most practical way of utilizing this effect in mass-spectrographic separation experiments would be to accelerate the ions to higher energies after they have been subjected to the magnetic separation.

I wish to thank Prof. Niels Bohr for his continued interest in the present investigation. Furthermore, I should like to thank Mr. W. Drost-Hansen and Mr. S. Møller-Holst for their assistance in the work on the mass-spectrograph of this Institute.

Normal Stress Coefficient in Solutions of Macromolecules

In a previous note[1], the most general possible stress versus strain-velocity relations for an incompressible visco-inelastic fluid have been given. They involve two physical parameters for the fluid, Θ and Ψ. Θ is the viscosity and Ψ is a new parameter which we shall term the 'normal stress coefficient'. These relations must also be valid for a visco-elastic fluid in steady-state laminar flow. From a phenomenological point of view, Θ and Ψ may be constants or they may depend on the strain-velocity invariants. If the fluid is in a steady state of laminar flow, parallel to the x-axis, the velocity gradient being parallel to the y-axis, both tangential and normal components of stress, t_{xy} and t_{zz}, exist at any point of the fluid, where

$$t_{xy} = \Theta\varkappa \text{ and } t_{zz} = -\tfrac{1}{2}\Psi\varkappa^2. \tag{1}$$

$\varkappa$ is the velocity gradient in the fluid.

Kramers[2] has calculated the contribution of dissolved high-polymer molecules to the viscosity of a solution, using an idealized 'pearl necklace' model for the high-polymer molecule. The molecule is considered to consist of a number of equal massive points connected by equal rigid links, which are capable of some measure of rotation about the mass-points at their junctions. A number of other simplifying assumptions are made in order to make the problem mathematically tractable. The contribution $\Delta\eta$ of N dissolved high-polymer molecules per c.c., each consisting of N links of length L, is given by

$$\Delta\eta = \frac{1}{36}\,\zeta L^2 N^2 \mathcal{N}, \qquad (2)$$

where $-\zeta\mathbf{v}$ is the force on a mass-point due to the solvent, if $\mathbf{v}$ is the velocity of the mass-point relative to the solvent in its neighbourhood. It is assumed that the solution is sufficiently dilute to make the interaction between the dissolved high-polymer molecules negligible.

Employing a method similar to that of Kramers, we have shown that the contribution to the normal stress coefficient Ψ for high-polymer molecules, in which the links are considered to be freely rotating, is given by

$$\Psi = \frac{1}{405}\,\frac{(\zeta L^2 N^2)^2}{4kT}\,\mathcal{N}, \qquad (3)$$

where k is Boltzmann's constant and T is the absolute temperature of the solution.

If the links in the high-polymer molecules are not capable of any rotation and are collinear, then

$$\Delta\eta = \frac{1}{72}\,\zeta L^2 N^3\, \mathcal{N}, \qquad (4)$$

and

$$\Psi = \frac{1}{1080}\,\frac{(\zeta L^2 N^3)^2}{4kT}\,\mathcal{N}. \qquad (5)$$

From (2) and (3) we obtain, for the case of flexible molecules,

$$\Psi = \frac{4}{5}\,\frac{(\Delta\eta)^2}{kT\mathcal{N}}. \qquad (6)$$

Similarly, from (4) and (5) we obtain, for the case of rigid molecules,

$$\Psi = \frac{6}{5}\,\frac{(\Delta\eta)^2}{kT\mathcal{N}}. \qquad (7)$$

We note that, if N is large, the assumptions of flexibility and rigidity lead to very different values for $\Delta\eta$ and Ψ, but the relations (6) and (7) between $\Delta\eta$ and Ψ differ very little.

It appears from the calculations that, in both the cases considered, the non-vanishing of Ψ arises from the orientation of the dissolved molecules in the flow-field, which—in both Kramers' calculation and ours—is assumed for simplicity to be undisturbed by the presence of the dissolved molecules.

For a 25·7 per cent solution of polystyrene in xylene, Ferry[3] gives the viscosity as about 220 poises at a velocity gradient of 9 sec.$^{-1}$. Taking the intrinsic viscosity as 2·5, we see that if the dissolved polystyrene molecules act independently of each other, the viscosity of the 25·7 per cent solution should be about 0·37 poises. In order to explain the much higher value of viscosity actually measured, we assume that the dissolved molecules interact and that for the purposes of calculation the effectively non-interacting flow units are no longer the $\mathcal{N}$ dissolved molecules but a much smaller number $\mathcal{N}'$ of groups of many molecules. A very rough estimate of this number $\mathcal{N}'$, which has only a limited physical significance, can be obtained from the figures given above, together with the molecular weight of the polystyrene. Introducing this in place of $\mathcal{N}$ in (6) and using the measured viscosity value for $\Delta\eta$, Ψ can be calculated.

From (1) we obtain, when $\varkappa = 9$ sec.$^{-1}$,

$$t_{xy} \approx 2 \text{ gm. wt./cm.}^2 \text{ and } t_{zz} \approx -18 \text{ gm.wt./cm.}^2. \qquad (8)$$

We see that t_{zz} is numerically greater than t_{xy}. In obtaining the formulæ (2) to (7), it is assumed that $t_{zz} \ll t_{xy}$, so that the result (8) has no quantitative significance. However, it shows that a concentrated high-polymer solution, such as that considered, should show quite appreciable values of the normal stress component, at any rate comparable with the value for the tangential stress component, even at such a low velocity gradient as 9 sec.$^{-1}$.

The above discussion is not intended to provide a precise method of calculating the normal stress coefficient, but merely to show qualitatively that a non-zero normal stress coefficient can arise from the orientation of high-polymer molecules in flowing solutions and that for concentrated solutions it may be expected to have a measurable value.

This investigation was carried out at this Institute under the sponsorship of the Reconstruction Finance Corporation, Office of the Rubber Reserve, while I was on leave from the British Rubber Producers' Research Association, Welwyn Garden City, Hertfordshire, England.

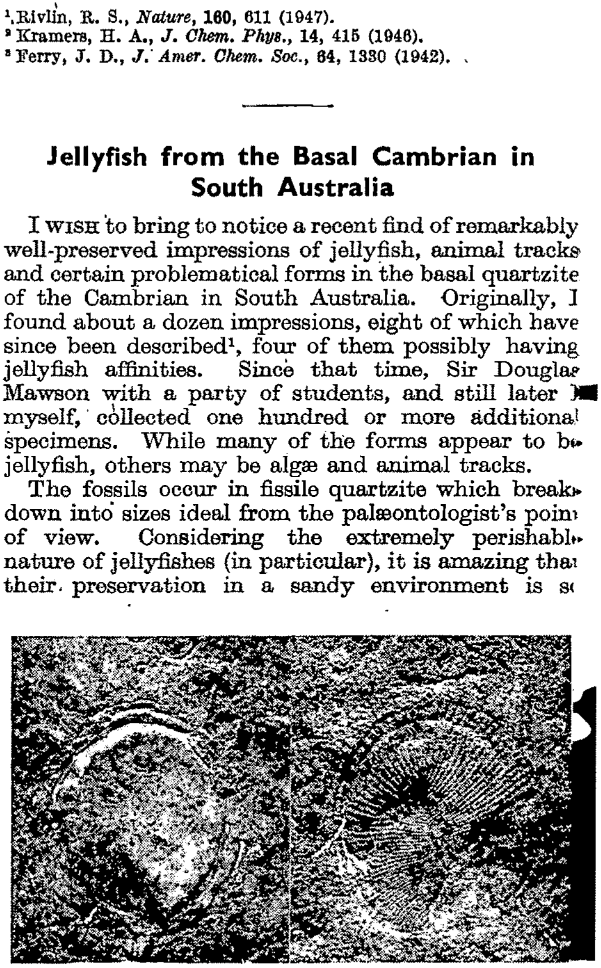
Jellyfish from the Basal Cambrian in South Australia

I wish to bring to notice a recent find of remarkably well-preserved impressions of jellyfish, animal tracks and certain problematical forms in the basal quartzite of the Cambrian in South Australia. Originally, I found about a dozen impressions, eight of which have since been described[1], four of them possibly having jellyfish affinities. Since that time, Sir Douglas Mawson with a party of students, and still later by myself, collected one hundred or more additional specimens. While many of the forms appear to be jellyfish, others may be algæ and animal tracks.

The fossils occur in fissile quartzite which breaks down into sizes ideal from the palæontologist's point of view. Considering the extremely perishable nature of jellyfishes (in particular), it is amazing that their preservation in a sandy environment is so



Beltanella gilesi Sprigg *Dickinsonia costata* Sprigg excellent (see photographs). Canals, (?) gonads and mouth structures are frequently clearly visible, and in one form, *Beltanella*, a velar membrane is present.

Now that a considerable amount of new material is available for description and comparison, it is hoped that a more complete study of these interesting forms will be possible. Criticisms and suggestions would be most helpful in the continuation of this study.

Cementiferous Paints and their Uses

THE reference by Dr. L. A. Jordan[1] to the possibilities of cementiferous paints as fireproof coverings for the interior of warships makes it advisable to supply an earlier chapter in the history of these paints. The fact that metallic particles interact with certain chlorides to give cement-like masses was noticed by Dr. U. R. Evans, of the University of Cambridge, when working on a Service problem in 1940. He later extended the idea to produce water paints which could be applied to a wet steel surface, and which provided cathodic protection to the steel, even where exposed at discontinuities. Such a paint was put into industrial use in 1942 in a plant where rapid corrosion cracking had caused frequent stoppages in a process of high war priority, and has been in use ever since. Here, the conditions are quite exceptional, and it is unlikely that the paints have any advantage in the average terrestrial situation.

Thornhill and Mayne carried out at Cambridge detailed study of the setting and protective mechanism, working for the Iron and Steel Institute Corrosion Committee (now the British Iron and Steel Research Association Corrosion Committee). Much work was also carried out, first by the Cambridge investigators, later at Caernarvon by J. C. Hudson, and finally at Millport by K. A. Pyefinch, on the possibilities of these paints for protecting steel plates immersed in sea-water; the results have been encouraging.

The Admiralty is represented on the Corrosion Committee, and the idea that the paints might be useful in combating the menace of rapidly spreading fires (such as occurs in ships painted internally with oil paints) appealed to those working on paint in the Admiralty Chemical Department at Portsmouth. Thornhill carried out some experiments late in 1943 on cementiferous fireproof paints, and took samples to Portsmouth in 1944. These were tested by the Admiralty chemists, who reported the coats to be insufficiently resistant to abrasion. Mayne then suggested the use of an overlying silica coat produced by means of ethyl silicate. Apparently this has solved the problem. Meanwhile, the Admiralty chemists appear to have continued researches on the paints, and have evidently achieved notable advances by the addition of industrial spirit, which allows the paints to be kept in a ready-mixed condition.

It is understood that ship trials have been carried out by the Admiralty, with encouraging results, of the possibilities of these paints as underwater protection paints.

Dr. U. R. Evans is anxious to emphasize the fact that these paints are unlikely to be of value except in certain special situations. Unauthorized statements seem to have appeared in the technical Press, and these have evidently led to misunderstanding. It can only lead to disappointment to apply a paint—or anything else—in the wrong situation.

Flint Flaking

WITH reference to the letter from Dr. T. T. Paterson under the title "Earliest Known Prehistoric Industry"[1], I wish to express my indebtedness to him for having brought his new discoveries for my examination at home, so that I could compare them with my collection of natural flakings. I have been familiar with patches of intensive flaking below the Weybourne Crag for many years[2]. On some I have counted 50 per cent of flaking among the stones—a not unusual frequency.

The evidences of localized sites may be misleading. For example, the flaking on such a site may be all of one date; but before drawing a conclusion one must inquire whether on a wider area an identical type of flaking is of miscellaneous dates. Again, an associated group of flaking is not necessarily a human working, it may be a 'Nature's workshop'; in other cases, abraded flakings have been drifted together upon the sub-Crag floor.

Neither this, nor any other disputed group, carries flaking that is superior to that from the sub-Eocene site at Grays. This occurred in the Bullhead Bed, locally modified by the addition of large flints brought in through solution of the underlying Chalk. Some flaking is general in the Bullhead Bed; but this was a localized site of special character, which, in other circumstances, could well have been mistaken for a human industry[3].

My point of view is that while it is not possible to distinguish human from natural flaking upon every separate specimen, I am convinced that mechanical movements under pressure, concussions and the like produce their respective groups of forms which are recognizable[4]. To the best of my judgment, the sub-Crag flakings conform to the distinctive characteristics of movements under pressure.

My tentative suggestion is that the whole of the effects of crushing, striation and flaking observed among the flints of the Crag sea-floor are due to the grounding of floating ice. At least, purely mechanical effects due to that, or some other cause, are conspicuous, and I submit that the problem of this remarkable flaking, with its rostro-carinates, flakes and edge-chipping, should be considered as a whole in association with the physical evidences.

HORMONE-MIMETIC AND OTHER RESPONSES OF THE SILKWORM (*BOMBYX MORI* L.) TO SOME POLYPLOIDOGENIC AGENTS

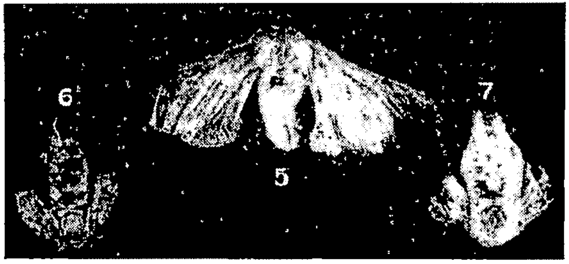
By L. J. HAVAS and J. KAHAN
Hungarian Biological Research Institute, Tihany

ACCOUNTS have been given by the senior author[1,2,3] of a series of 'hormonal' responses of plants and animals to the polyploidogenic agent colchicine. He has also repeatedly pointed out that such effects were, as often as not, independent of the polyploidizing action of the alkaloid. Other authors have come to similar conclusions[4,5,6].

Hirobe[7], using colchicine, has elicited blocked mitoses and polyploidy in the silkworm. Preliminary experiments, carried out according to the plans of the senior author by H. Tangl (unpublished), gave no indication of such effects. We decided in consequence to change the methods of administration of the drug and to repeat the treatments, following the method of Clark, Hanson and Rowntree[8], through several generations, in order to obtain, if possible, cumulative hormonal effects. The role of such effects in eliciting polyploid mutations in plants was shown by Havas[9]. The first stage of this work is described below.

The experiments were carried out partly on 'bivoltinized' and partly on freshly laid eggs or on recently hatched larvæ. In some groups the treatments were repeated after each moult up to, and including, the pupal stage. One thousand six hundred animals were treated in all. The polyploidizing agents used were colchicine, acenaphthene[10], and podophyllin, a resin isolated from *Podophyllum peltatum*. The first two are well known. Dr. I. Cornman has directed our attention to the third, his own and the experiments of other workers[11,12] having demonstrated that it is a powerful agent in inducing blocked mitoses and polyploidy in plant and animal tissues.

The eggs were treated with colchicine or podophyllin in Petri dishes, 40–60 eggs of each group being put into a 1 : 2,000 or 1 : 5,000 solution of the drugs. Water was used for the controls of the colchicine groups, and a 1 : 2,000 solution of acetone for the controls of the podophyllin-treated animals, because the resin was dissolved first in a small quantity of acetone. The methods of treatment of the larvæ with colchicine varied in the different groups. Some groups were placed in Petri dishes on filter paper wetted with solutions of the drug ranging from 1 : 10,000 to 1 : 400,000, or the caterpillars were painted with them. The combined method was also used. In some groups the drug was injected into the caterpillars or the pupæ.



The acenaphthene treatment of eggs and larvæ was also carried out in Petri dishes. 0·05 mgm. of acenaphthene was dissolved in 0·5 ml. of ether, and the solution was poured into the inverted lid, which was put in place when the ether had evaporated. The agent was left to act by sublimation for from 45 minutes up to 16 hours. Only a few examples of the results obtained will be given here, a more detailed account being in preparation.

Colchicine at a concentration of 1 : 2,000 stimulated the hatching out of the eggs but, curiously enough, inhibited it at a concentration of 1 : 5,000. In the same concentrations podophyllin had the opposite effects. The death-rate of both the 'colchicine' and 'podophyllin' animals was in direct relation to the concentrations, 1 : 2,000 being toxic. Acenaphthene either inhibited entirely the emergence of larvæ from bivoltinized eggs, or its effects were practically nil.

The accompanying table shows the effects of colchicine (1 : 100,000) and of acenaphthene (10 hours) on growth and weight of the caterpillars.

Days		Length (mm.)	Weight (gm.)
11	Colchicine	12·19 ± 1·63	0·0276 ± 0·00102
	Control	11·45 ± 1·75	0·0248 ± 0·00391
24	Colchicine	30·90 ± 4·42	0·264 ± 0·03778
	Control	28·60 ± 4·97	0·185 ± 0·03218
32	Colchicine	40·60 ± 7·86	0·880 ± 0·1705
	Control	36·20 ± 6·66	0·573 ± 0·1054
14	Acenaphthene	6·00 ± 1·00	0·0040 ± 0·00068
	Control	15·40 ± 3·16	0·0423 ± 0·00868
28	Acenaphthene	30·00 ± 8·16	0·327 ± 0·0889
	Control	38·60 ± 4·74	0·538 ± 0·0462
41	Acenaphthene	47·70 ± 7·52	0·918 ± 0·0145
	Control	62·50 ± 5·94	2·235 ± 0·2222

It was further observed that larvæ treated with colchicine at a concentration of 1 : 100,000, and still more at concentrations of 1 : 200,000 and 1 : 300,000, began to spin their cocoons earlier than did the controls and reached the chrysalis and imago stages earlier. Acenaphthene—the definite narcotic action of which was also noticed—retarded all these stages of development and metamorphosis. There seemed to be only one sphere of action in which colchicine and acenaphthene produced comparable effects, and this was the induction of morphological anomalies and colour changes. No. 7 of the photograph (kindly taken by Dr. L. Felföldy) shows one of these aberrant imagos with hypertrophied thorax and stunted and partly truncated wings, both bearing yellow maculæ, and No. 6, a stunted variation of coffee-brown colour. No. 5 represents one of the controls. Colour changes were also observed in the larval stage under the influences of colchicine and acenaphthene. Insects with vestigial antennæ or entirely lacking them were frequent in both groups. A rather curious phenomenon was encountered among the 'colchicine animals': an imago, the head, thorax and wings of which were still enclosed in the hard chitinous pupal covering, and which, in spite of this, had laid eggs.

The role of the corpora allata being well known in the above developmental and growth processes, as well as in the colour changes[13,14], the hormone-mimetic effects of the agents may be ascribed, among others, to their influence on the polarity of translocation or on the synthesis of the manifold products of this endocrine organ. However, as regards the inhibitory actions of acenaphthene, the part played by its narcotic effects and the consequent suspension of important vital processes must also be taken into account in interpreting the reactions elicited.

It is not yet known whether the morphological anomalies observed are to be considered as simple variations, as the ephemeral manifestations of hormonal or pharmaco-dynamical actions, as '*Dauer*'-modifications, or as true mutations. The manner of the 'mendelization' of their offsprings will answer these questions next season.

These investigations were partly aided by grants of the Hungarian Department of Agriculture, Bureau of Researches.

INDUSTRIAL CO-OPERATION

THE delegates to the annual conference of the British Association for Commercial and Industrial Education, which was held at Ashridge in October 1947, were welcomed by the president of the Association, Sir Charles Tennyson, who stated that "the task confronting us to-day will require a range of knowledge in natural science, economics, sociology and psychology of which our grandfathers can never have dreamed, and a degree of perseverance, common sense and mutual consideration which must be a severe tax on human frailty. It is clear that education can make an inestimable contribution to the solution of these difficulties but . . . there seems to be a general consensus of opinion that education has made the mistake of confining itself to 'subjects', dealing with these in isolation and not relating them sufficiently to the needs and circumstances of society and man's everyday life and avocations.

"On the other hand, industry and commerce . . . have failed to realize that they have a responsibility to promote the development of individual capacity and sense of citizenship. They have also failed to realize how much academic training can do to improve the efficiency of the young employee who has been regarded simply as an economic unit to be made as immediately productive as possible at the smallest expense. That is not the way to produce skilled workmen, efficient managers, broadminded and creative technicians or good citizens."* Sir Charles then declared that the motive in calling the delegates together was the belief that unless educationists, industrialists and representatives of the workers come together to deal with this question of education and training in the spirit of research and whole-hearted co-operation Britain has little chance of overcoming its difficulties.

The initial address was given by Mr. F. C. Hooper, formerly director of business training to the Ministry of Labour and National Service, who dealt with the part which management should play in bringing about industrial co-operation. When an administration is faced with the need to change a situation, he said, its first essential task is to change the habit-patterns that have been built up under and by the old situation that is to be changed. The immediate situation we wish to change is one of poor or half-hearted co-operation between management and labour in business and to establish in its place a situation of full and enthusiastic co-operation in which management and labour are a real organic working team. This co-operation can only come if both parties recognize that they possess a single over-riding common interest which wholly justifies them in establishing a common aim and which inspires them in working together to achieve it. Of the forces which stand in the way of establishing full co-operation one of the most important is the actual nature of the trade unions. Formed as fraternities to curb and combat the power of employers, to-day they have become essentially 'antibodies'. When management considers how it can most effectively attain the co-operation of its employees, it must always reckon with the fact that the rank and file of organised labour are extremely suspicious of management and that this suspicion will not be eradicated in any short term. The only way in which antibodyism and suspicion could be abolished would be by the logic of events from without and the efforts of trade union leadership directed to the same end from within. Mr. Hooper then suggested various means by which the climate of work could be made favourable to produce the maximum response by all workers in industry, and suggested that, in his opinion, schemes of education and training are of paramount importance.

Replying for the trade unions, Mr. Harold Clay, assistant general secretary of the Transport and General Workers Union, stated that over a very wide field in industry, especially among the industrial workers, there was considerable suspicion, doubt and hesitation about schemes for education and training. There undoubtedly existed in the minds of the wide body of the working population the idea that some of the 'enlightened' ventures that are now being embarked upon are merely another form of dope or opiate to keep the workers quiet at this particular time. In his opinion, education and training was part of a much wider problem, and until a real sense of social purpose had been built up which was accepted by all sections in industry, any attempt to find a solution to our present difficulties would fail. This sense of social purpose should be quite distinct from individual advantage, firm advantage or industry advantage. Relationships generally between management and workers, and those they represent, should be such that co-operation must be possible over a very wide field. "There must be opportunities for the discussion of all those issues that affect, or appear to affect the interest of the workers, and this includes quite a number of problems that have hitherto been regarded as the sole concern of management."

Other speakers went on to consider how more effective co-operation could be achieved between the planners of education and the planners in industry and commerce, as well as those aspects of education and training which had proved effective in promoting good relationships between the employee and employer. This was followed by a session in which Mr. Noel Hall, principal of the Administrative Staff College at Henley, discussed the further training of higher management and particularly the way in which this training would be given at the Administrative Staff College.

---

* "The Short Road to Industrial Co-operation." Published by the British Association for Commercial and Industrial Education, 107 Baker Street, London, W.1. 5*s*.

Finally, the industrialist's point of view was put clearly and forcibly by Sir Ronald Weeks, deputy chairman of Vickers, Ltd., who defined the present obligations of both employer and employee. In his view the employer must regard himself as the trustee, be honest and fair in all his dealings, study the psychology of his employees, do everything possible to ensure good working conditions, know his own job and train his staff accordingly, pay an adequate wage for an honest day's work, endeavour to give his employees a sense of security and reasonable incentives for advancement, and finally, he must provoke a sense of loyalty and a 'sense of belonging'. The employee should observe obedience to rules and a sense of discipline, loyalty to the employer, and an honest day's work.

Sir Ronald emphasized Mr. Clay's belief that spontaneous co-operation cannot come without a sense of social purpose, and indicated that to-day the size of the pay packet on one side and the profit motive on the other are considered to be much more important than the conception of the universal and social purpose in industry. Sir Ronald then put forward various suggestions for the future improvement of industrial relations, indicating ways and means in which schemes of education and training for all grades could be introduced and implemented.

Altogether some 170 delegates attended the conference and, although they represented industries and public services having widely different problems and approached the discussion from widely different points of view, the conference was remarkable for the almost complete unanimity about the solutions that should be applied to Britain's economic crisis. Among the delegates were many representatives of firms who have been world pioneers in schemes of employee education and training and who have proved by experience that such schemes are eminently practical and beneficial. At this time of emergency their experience should not be ignored. T. H. Hawkins

---

HISTORY OF SCIENCE IN EDUCATION

A JOINT meeting of the British Society for the History of Science with the Science Masters' Association, the Historical Association and the Association of Women Science Teachers was recently held at the Science Museum to discuss the subject "The Place of the History of Science in Education". The meeting was very well attended, and the chair was occupied by Dr. E. J. Holmyard, who took the opportunity of welcoming Prof. George Sarton as an honorary member of the British Society for the History of Science. The opening speakers were Dr. F. Sherwood Taylor, Mr. G. Fowles (a former chairman of the Science Masters' Association), Mr. S. M. Toyne (chairman of the Council of the Historical Association) and Miss L. E. Higson (secretary, Association of Women Science Teachers).

Dr. Sherwood Taylor said that he believed the principal aim of teaching science in the schools was to enable young people to make wise and sound decisions in their daily life. The teaching should also make clear how far, and in what regions, one may trust science. Instruction in the history of science could obviously provide a valuable means to this end. There was too much tendency at the present day to teach factual rudiments only, and he would like to see more insistence upon scientific method. Where this involved a repetition of famous historical experiments, difficulties were bound to arise, since many of them did not lend themselves to the conditions of school curricula. There seemed to be a great opportunity for historical scientific films in this connexion, but such films must be of high accuracy or they would do more harm than good.

Mr. Fowles said that, in teaching science in schools, the psychological factors were very difficult in that only about 5 per cent of the pupils could ever reach the standard represented by a university scholarship, and that the method of presentation had to be conditioned mainly by the needs of the remaining 95 per cent. So far as the historical method of teaching science was concerned, he thought there were three different aspects which he would describe as anecdotal, recapitulatory and evolutionary. Everybody was agreed that the anecdotal aspect was useful; but he doubted whether it was of value in explaining scientific method. The recapitulatory system was not altogether without defect, since pioneering work did not always provide the most direct or logical solution of the problem involved. General evolutionary consideration of scientific advance had more to recommend it, and this would be particularly valuable in teaching science to classical sixth forms. He agreed that some knowledge of the history of science was of great importance, but felt that it should form part of the general history course rather than of the science course.

Mr. Toyne described the methods he had adopted of teaching the history of science to boys on all sides in a public school. He felt that the history of science should form a part of the history course, but not at the expense of the history normally taught. He emphasized the fact that social history cannot properly be explained without a knowledge of the history of science.

Miss Higson expressed the view that instruction in the history of science would be of advantage to all pupils in schools, especially those of sixth-form age. She had been distressed to find how little mention of men of science and scientific discovery was made in the standard histories used in the schools, and gave some examples. Apparently the only man of science to attract the attention of historians was Darwin. Miss Higson also remarked that she felt that science and its history should form an integral part of the 'current events' periods in schools, and agreed with Dr. Sherwood Taylor's plea for more science films.

Dr. Sarton said that in his opinion the value of the history of science was threefold. In the first place it was essential for science itself. Secondly, it formed an excellent introduction to philosophy. Thirdly, it had inherent cultural advantages, and these he would rate the highest. He gave an account of his own two-year course on the history of science at Harvard, in which he presented his students with a general survey of the developments of science and scientific thought from the earliest times to the present day, in four sessions of thirty-five lectures each.

The discussion then became general, and the consensus of opinion was that a very strong case had been made out for the inclusion of the history of science in the course for both schools and universities, and most speakers agreed that the teaching should form part of general historical study.

THE GOVERNMENT SOCIAL SURVEY

THE Government Social Survey is a social research unit created to provide Government departments with information about the habits, opinions and conditions of the people. It was set up in 1941 in response to specific administrative needs: to obtain information, for example, about war-time shortages of consumer goods and their distribution, and about the effectiveness of the information campaign of the Ministry of Food. The Survey was from the beginning controlled by the Home Intelligence Division of the Ministry of Information; and, at the moment, it is a division of the Central Office of Information. So far no final decision has been made about how the Survey is to be fitted into the Government apparatus.

The Social Survey has made nearly 140 different studies over the last five years, each of which has been individually authorized by the Treasury on the basis of a demonstrated need on the part of a Government department. The public has been interested and willing to co-operate in this work, as is shown by the fact that half a million interviews have been made, and refusals to co-operate have been of the order of half of one per cent on an average.

The wide scope of the Survey's work and its establishment as a permanent Government research organisation have demonstrated that there is a place for the social scientist in the machinery of government, and that scientific method can be applied to the social field to help the administrator to deal with an ever-increasing range of social questions. In Great Britain there is much leeway to make up in this field. We have come a long way from Charles Booth's monumental survey of "London Life and Labour", made at the end of the nineteenth century. The early English sociologists had discussed the way in which the many activities of society were interrelated; and Profs. A. L. Bowley and John Hilton had introduced us to the value of sampling techniques. But British studies were in the main concerned with establishing facts about an under-privileged section of the population, for they dealt with poverty or problems arising out of poverty; and they were, in the main, local studies.

In the United States, on the other hand, the existence of many national minorities, the use of market research—really a special type of social survey—for business purposes in the large home market, and the great stimulus to social inquiry prompted by the New Deal had forced the development of the social science disciplines. The American Institute of Public Opinion (the Gallup Poll) is an example of the kind of organisation that was developed during this period as a result of the interest in the everyday opinions and feelings of ordinary people.

The war-time inquiries of the Social Survey were a response to immediate administrative needs. The Survey collected the data on which those responsible for the organisation of the civilian side of the War based their policies: for example, information about many aspects of the problems arising from the ationing of scarce consumer goods. Thus, soon after he beginning of clothes rationing, study was made of the special clothing needs of workers in occupations where the conditions of work caused extra wear and wear on clothes, to determine how far supplementary allowances of coupons were required. Indeed, from early in 1942 regular studies were made for the Board of Trade to discover the extent of current shortages, and which sections—by population and geographically—were most affected. Man-power policy was of critical importance. The Survey aided in securing the best possible use of the available labour-power. For example, when women were registering for war-work for the first time, studies were made of the extent to which each woman felt satisfied with the kind of interview she had had. Studies were also made of the reasons why women were reluctant to join the A.T.S. and nursing.

These war-time studies were directly utilitarian. Others, of the same kind, included the use of demobilization coupons: for the issue of a demobilization coupon allowance to members of the Forces made available an enormous number of coupons, supplementary to existing civilian coupon stocks, which were capable of completely changing the previous pattern of effective demand. On the basis of studies of coupon disbursement by newly demobilized men and women, the Social Survey was able to produce information which enabled the Board of Trade to estimate the probable effect on total demand of these supplementary coupon issues, and to change its plans accordingly. Other investigations carried out by the Survey included: a survey of the extent to which economies could be made, with the least possible inconvenience to the public, in the use of some kinds of food; credit buying, a study for the Board of Trade of the extent of instalment and hire purchase trading; getting to work, a study for the Ministry of War Transport of workers' transport difficulties; inquiries on the extent to which the technical information provided for farmers by the Ministry of Agriculture was actually being used, the impact of the 'Dig for Victory' campaign on home horticulture, and a survey of garden and allotment food production. In February 1943 an investigation was made into canteen, British Restaurant and café feeding and packed meals. This was carried out for the Ministries of Health and Food, which needed to know in detail something of the feeding habits of the people: what kinds of foods formed the diet of the normal household, how these foods were prepared, and when meals were eaten. The Ministry of Food was providing extra rations for workers in canteens and British Restaurants, but did not know how many and what types of workers made use of these facilities, or what reasons there were for not doing so.

There have also been made a number of intensive, detailed studies which have had implications outside war conditions: for example, Scottish mining communities, an inquiry made for the Department of Health for Scotland, the Clyde Valley Planning Advisory Committee, and the Central and South-east Scottish Planning Advisory Committee in the autumn of 1946, had reference to the need for building new mining communities in the expanding coalfields of Fifeshire. Answers were given to the four following vital questions: (1) To what extent are existing mining communities satisfactory? (2) What is the possibility of transferring miners from areas where coalmining is declining to areas where mining is expanding? (3) What are miners' attitudes to the future of the mining industry, as they affect their attitude to alternative employment, and the attitude of their children to entering this, or other, industries? (4) What are the main social needs of a number of entirely new mining townships to be built in Fife?

During the War there were fears of a large increase of minor illnesses. It became urgent for the Ministry of Health to have some measure of the amount of illness in Britain and of the proportion of minor ailments. Successful experiments were carried out by the Social Survey to test the possibility of regular surveys of illness. From the beginning of 1945 the Survey has shown that morbidity statistics could be systematically produced, for the first time in history, covering all illnesses of the whole population, and not merely notifiable diseases. These statistics are published by the Registrar General. They are of obvious use in the preparations for the full operation of the National Health Act. This survey of sickness permits a precise estimate of the amount of working-time lost through all illness, or through the various types of illness, and also which are the major illnesses in particular regions or groups in the population.

Other intensive studies have dealt with: domestic heating and lighting, to help the Building Research Station and committees of the Ministry of Works prepare building standards; old people's occupation and family responsibilities, in connexion with a long-term investigation to be made by the Industrial Health Research Board; and water heating, an inquiry carried out in March 1947 for the Ministry of Works. The last-named report gives the distribution of water-heating appliances in Great Britain. It examines their distribution by type of district and region, type and age of dwelling and economic group; the extent to which they are used, their relative popularity, and the complaints they give rise to. There is also information about the use of laundries, and bathing habits. Studies are now being planned of consumer expenditures. These budgetary inquiries are designed to provide detailed information about expenditure among all sections of the population. The continuous flow of data to be supplied by these studies will help to provide the basis for a long-term employment policy, and they may be of use in helping to analyse the effects of taxation.

Thus, the Social Survey is now producing social data in a very wide field, and by its work is demonstrating that social scientists can develop observational techniques which provide adequate factual material from which to draw socially valid conclusions. An essential technique developed by the Social Survey is that of population sampling. Trained field-workers interview samples of the general public, or of particular sections, with a recording schedule devised so that the results of the inquiries made can be expressed statistically. Two hundred local investigators are so distributed throughout the country that they can reach the whole population. There is a research staff of twenty, and a technical staff of sixty (dealing with machine tabulation, computation and coding). The research officers include anthropologists, psychologists, sociologists, economists and statisticians. The Survey budget for the past year amounted to £60,000.

The main conclusions from war-time experiences, as stated by Mr. Louis Moss, director of the Government Social Survey, in a paper read to the Institute of Public Administration, in April 1946, are: first, the general utility of the information obtained; second, the importance of public co-operation; third, the general feasibility of sampling as a technique capable of producing information in many different fields; fourth, the value of the personal interview as a method of collecting detailed information on factual matters, and matter of opinion; fifth, the knowledge of the kind of organisation necessary to carry out such surveys systematically on a national scale; and sixth, the value of the mixed team—not only of social scientists, but including also natural scientists. For example, the co-operation of technicians and physical scientists with the social scientists on the Survey's staff has made it possible to devise methods of work which for the first time are capable of providing a picture of the complex housing situation of Britain.

The techniques employed by the Survey are helping to lay the basis for an empirical social science. They have produced basic data suitable for the studies of the research worker in economics. They have shown the way in which changes in demand could be studied in a quantitative manner. In addition, the study of attitudes is a field for the social psychologist and the sociologist. For example, in mining, not only are the social and industrial conditions of importance, but also the attitudes of potential recruits. Similarly, in the field of behaviour there is much for the social psychologist to do. The social scientist has still a great deal to learn, and the work of the Social Survey is providing a detailed experience of methods and an accumulation of social data which will be of great help.

What of the future? The statement of the Lord President of the Council in the House of Commons, when announcing the panels of his Industrial Productivity Committee, that the social sciences had a part to play, is a recognition that adequate administrative and executive action in the complicated social and economic fields demands a scientific approach. Thus, survey techniques will surely have a part to play in studying consumer needs in austerity Britain, where limited resources are available for consumer goods production.

War-time experience demonstrated that the Social Survey reports were of value when implemented at administrative level. Therefore, in arriving at a final decision about the place of the Survey in the Government machine it would be necessary to ensure the closest contacts with those responsible for making decisions on social and economic policy.

The correct employment of the Social Survey will help to make more valid Graham Wallas' early comment that "the Government has come to be engaged not merely in preventing wrong things from being done, but in bringing it about that the right things shall be done".

Maurice Goldsmith

INSECTICIDAL SMOKES

APPLYING insecticides in the form of a smoke is a long-established practice. Pyrethrum has been used in this way by the Chinese for centuries, and burning nicotine shreds in glasshouses has been a common practice in Great Britain and elsewhere for a long time. These practices were empirical and there were little or no quantitative data on their effect.

The smoke may be produced by dropping the insecticide on to a hot plate, by indirect heating in a specially designed generator, or by intimate mixing with a combustible powder which is then ignited.

During the Second World War, the use of insecticidal smokes propagated by mixing the insecticide with a pyrotechnic powder was considered for use in the campaign against the Japanese. Some work was done on the subject at the Chemical

Defence Experimental Station at Porton by E. W. Bateman and G. D. Heath (*J. Soc. Chem. Ind.*, **66**, 325; 1947). In this paper the main technical principles involved in the generation of insecticidal smokes are set out and the development of a pyrotechnic insecticidal smoke generator is described.

When this method is employed, one of the crucial problems is to obtain a suitable pyrotechnic powder. The requirements of this powder as listed by Bateman and Heath are that it should be capable of burning slowly and smoothly when mixed with at least an equal weight of insecticide; that the ignition temperature should be as low as possible, in order to avoid excessive heating before combustion occurs; that it must give rise only to products which will not react with the insecticide, and these products should so far as possible be gaseous, since the presence of a hot residue assists the decomposition of the vapour of the insecticide which is forced to pass through it; it must not be unduly sensitive to friction or to heat and should not be hygroscopic, since it must be capable of being handled with safety and of withstanding storage for long periods under tropical conditions. Experiments are described using potassium chlorate and sucrose as the pyrotechnic mixture, and D.D.T. or benzene hexachloride as the insecticide. With these two insecticides there is the complication that hydrochloric acid may be liberated on storage, and a stabilizer should be added. Magnesium oxide was added for this purpose.

Since the War considerable interest has been taken in the use of this method for the control of the pests occurring in glasshouses, warehouses, farm buildings, etc., and they are now being marketed commercially. The generators consist essentially of a thin-walled metal cylinder containing the insecticide mixed with the pyrotechnic powder, an igniter composition and a fuse. The fuse is ignited, and this in turn ignites the starting mixture which sets off the pyrotechnic mixture. The smoke issues through a cooling baffle on top of the cylinder. The baffle prevents ignition of the cloud.

Smoke generators with D.D.T. and azobenzene as lethal agents are being sold by the Murphy Chemical Co., Ltd., and Plant Protection, Ltd., are selling azobenzene smoke generators and 'Agrocide' smoke generators. The 'Agrocide' generator contains the gamma isomer of benzene hexachloride as lethal agent. The smokes containing azobenzene are intended primarily for the control of glasshouse red spider mite, and the D.D.T. and 'Gammexane' smokes for the control of a number of insect pests.

The Murphy Chemical Co. at a recent demonstration held at Ryder's Nurseries showed how easy it is to fill a glasshouse with insecticidal smoke by this method. The advantages claimed for this procedure are that it is cheap and quick to apply, and labour costs are reduced to a minimum; that it gives a far more uniform distribution of the insecticide than spray application, coating both sides of the foliage and penetrating to every part of the glasshouse. The generators are self-contained, needing no apparatus for distribution. They are simple and clean to use and storage space is considerably reduced. It seems quite possible that the method may form a useful and certainly convenient addition to the existing techniques for the application of insecticides; but more information, both physico-chemical and biological, is required before its value can be accurately assessed.

In addition to the practice of gaseous fumigation and spraying in an aqueous medium, the use of aerosols produced from solutions of the toxic chemicals in propellant gases liquified under pressure, and of concentrated solutions of insecticides atomized by means of compressed air, are now being studied, and smoke generation must stand comparison with all these methods.

At first sight it would seem that smoke generators will give a better distribution and penetration than any method short of fumigation, but will have less residual effect than the aerosols, compressed air atomization and spraying. It also seems likely that the method can be used in situations where successful fumigation would not be possible.

It would therefore appear that insecticide smoke generators are most likely to be used where good distribution and penetration are required and where residual effects are of secondary importance, in situations where successful fumigation would be difficult. Although at present they are marketed for indoor use, it appears that in certain circumstances they may be useful outdoors. One limiting factor in the use of this method is likely to be the amount of destruction of the active chemical occurring during the production of the smoke.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, April 12

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5.30 p.m.—"Aerial Mountaineering" (Technicolour Film with Commentary by Colonel Walter A. Wood).

Tuesday, April 13

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Future Trends in the Design of Receiving Aerials" (to be opened by Mr. E. M. Lee).

Sheffield Metallurgical Association (joint meeting with the Sheffield Society of Engineers and Metallurgists, at the Royal Victoria Hotel, Sheffield), at 6.15 p.m.—Dr. Ulick R. Evans: "Thin Films on Metals".

Manchester Geographical Society (in the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Brigadier R. A. Bagnold: "Desert Sand Dunes".

Women's Engineering Society (at 35 Grosvenor Place, London, S.W.1), at 7 p.m.—Miss L. Chitty: "Structural Engineering".

Society of Instrument Technology, North-West Section (at the College of Technology, Manchester), at 7.15 p.m.—Mr. H. Schmitt: "Automatic Control Applications in the Chemical Industry".

Royal Anthropological Institute (at University College, Gower Street, London, W.C.1), at 8 p.m.—Prof. Percival R. Kirby: "The Trumpets of Tut-Ankh-Amen and their Successors".

Tuesday, April 13—Thursday, April 15

Institute of Physics, Stress Analysis Group (in the English Theatre, The University, Edmund Street, Birmingham).—Conference on "Stress Analysis".

Wednesday, April 14

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. Henry S. Horsman: "District Heating".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Major H. C. Gunton: "Phenological Report".

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. S. T. Minchin: "An Account of some Solid State Properties of Petroleum Waxes in Terms of their Composition".

Institution of Electrical Engineers, Transmission Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. W. Wanger: "Technical and Economic Aspects of the Transmission of Electrical Energy over Long Distances".

British Institution of Radio Engineers, North-Eastern Section (at Neville Hall, Westgate Road, Newcastle-upon-Tyne), at 6 p.m.—Prof. M. G. Say: "The Pulse Signal".

British Institution of Radio Engineers, Merseyside Section (in the Lecture Room, Liverpool Engineering Society, 9 The Temple, 24 Dale Street, Liverpool), at 6.45 p.m.—Mr. M. P. Johnson: "Some Aspects of Moderate Precision Temperature Control in Communication Engineering".

Television Society (at the Cinematograph Exhibitors' Association, 164 Shaftesbury Avenue, London, W.C.2), at 7 p.m.—Mr. K. C. Macleod: "Radio Frequency E.H.T. Supplies".

Wednesday, April 14—Friday, April 16

Electrical Association for Women (at Southport).—Twenty-third Annual Conference.

Thursday, April 15

Chadwick Public Lecture (in the Architectural Theatre, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Mr. Thomas Ritchie: "The Sanitation of Buildings" (Bossom Gift Lecture)*.

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. Frank Dixey: Talk; Dr. W. B. Pollard: "The Detection, Separation and Microtitration of Iridium"; Mr. P. H. Kitto: "A New Form of Thermal Precipitator".

Institution of Electrical Engineers, Installations Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. J. N. Aldington and Mr. A. J. Meadowcroft: "The Flash Tube and its Applications".

Illuminating Engineering Society, Manchester Centre (in the Reynolds Hall, College of Technology, Manchester), at 6 p.m.—Mr. H. C. Ruff: "New Lamps—New Uses, and New Lighting Techniques".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. W. E. W. Petter: "The Aerodynamic Problems of High Altitude Design".

Royal Photographic Society, Scientific and Technical Group (at 16 Prince's Gate, London, S.W.7), at 7 p.m.—Mr. H. S. Tasker: "Speed and Contrast in X-Ray Work".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. R. E. Rewell: "Diseases of Tropical Origin as seen in Captive Wild Animals".

Pharmaceutical Society, Manchester, Salford and District Branch (in the Council Chamber, Houldsworth Hall, Manchester), at 7.45 p.m.—Annual General Meeting.

British Institute of Radiology (at 32 Welbeck Street, London, W.1), at 8 p.m.—Sir Ernest Rock Carling: Mackenzie Davidson Memorial Lecture.

Thursday, April 15—Saturday, April 17

Royal Institute of Chemistry (at Birmingham).—Annual General Meeting.

Thursday, April 15

At 3 p.m. (at the Central Technical College).—Exhibition, "The Chemist in the Midlands", to be opened by Mr. Roche Lynche; at 6 p.m. (at the University, Edmund Street).—Prof. R. P. Linstead, F.R.S.: "The Chemical Research Laboratory, Teddington".

Friday, April 16

At 11 a.m. (at the Botanical Gardens, Edgbaston).—Prof. Maurice Stacey: "The New Fluorocarbon Chemistry".

Saturday, April 17

Visits to the University and the Barber Institute of Fine Arts, Chance Bros. glassworks at Smethwick, and Marston, Thompson and Evershed's brewery at Burton-on-Trent.

Friday, April 16

Institution of Chemical Engineers (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 11.45 a.m.—Twenty-sixth Annual Corporate Meeting; at 2.30 p.m.—Mr. H. W. Cremer: "The Chemical Engineer and Civilisation" (Presidential Address).

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. R. W. Wild: "The Electrical Measurement of Pressure and Strain, with particular reference to the Testing of Circuit-Breakers".

Institute of Navigation (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 5.50 p.m.—Commander W. E. May: "The Future of the Magnetic Compass".

British Institute of Radiology (at 32 Welbeck Street, London, W.1), at 8 p.m.—Prof. W. T. Astbury, F.R.S.: Silvanus Thompson Memorial Lecture.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. E. V. Evans: "The Gas Industry".

Institute of Welding, North London Branch (at Manson House, 26 Portland Place, London, W.1).—Annual General Meeting.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Physical Chemist or Physicist in the Physics Department—The Secretary, Royal Cancer Hospital (Free), Fulham Road, London, S.W.3 (April 15).

Lecturer (Grade II or Grade III) in Physics, and an Assistant Lecturer (Grade III) in Physics—The Secretary and Registrar, The University, Bristol 8 (April 20).

Assistant Lecturer in Chemistry—The Secretary, The University, Edmund Street, Birmingham 3 (April 24).

Research Assistant (Grade II) in the Science Museum Library—The Director and Secretary, Science Museum, South Kensington, London, S.W.7 (April 30).

Headships of the Departments of Botany, Zoology, Chemistry, Physics, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (May 1).

Assistant Lecturer (Grade III) in the Department of Geology—The Registrar, The University, Liverpool (May 1).

Lecturer in Zoology (with special qualifications in Genetics or Marine Zoology)—The Secretary, The University, Aberdeen (May 1).

Applied Mathematician in the Department of Electrical Engineering—The Secretary, Imperial College of Science and Technology, South Kensington, London, S.W.7 (May 1).

Professor of Chemistry—The Secretary and Registrar, University College of North Wales, Bangor (May 1).

Senior Cyclotron Engineer—The Director, Radiotherapeutic Research Unit, Hammersmith Hospital, Ducane Road, London, W.12 (May 10).

Assistant Lecturer and Demonstrator in the Biology Department, an Assistant Lecturer and Demonstrator in the Chemistry Department, an Assistant Lecturer and Demonstrator in the Physics Department, a Lecturer (with qualifications in Dietetics) and Assistant Lecturers and Demonstrators in the Physiology Department—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8 (May 10).

Lecturer (man or woman) in Biochemistry—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (May 14).

Lecturer in Meteorology—The Secretary of Faculties, University Registry, Oxford (June 1).

Plant Pathologist in the East African Groundnuts Scheme—The Personnel Department, Overseas Food Corporation, Unilever House, Blackfriars, London, E.C.4.

Chemist (with Honours Degree) for research work on problems of Chemical Microbiology—The Secretary, Wright-Fleming Institute of Microbiology, St. Mary's Hospital, Paddington, London, W.2.

Forestry Expert for the Directorate-General of Agriculture, to act as a Deputy to the Head of the Iraqi Forestry Department—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.18183 (3C).

Lecturer in the Department of Chemistry—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

Organic Chemist for research work on problems connected with the bleaching, dyeing and finishing of flax yarns and fabrics—The Director, Linen Industry Research Association, Linen Research Institute, Lambeg, Lisburn, Co. Antrim.

Lecturers in (a) Chemistry to B.Sc. standard, and (b) Physics to B.Sc. special degree standard—The Clerk, Northern Polytechnic, Holloway, London, N.7.

Lecturer in Biology—The Clerk to the Governors, Battersea Polytechnic, Battersea, London, S.W.11.

Biochemist (non-medical)—The Secretary-Superintendent, County Hospital, Lincoln.

Assistant Experimental Officers (2, Chemists, male) in the Plant and Animal Products Department, for laboratory work in connexion with investigations of Empire raw materials of plant and animal origin—The Establishment Officer, Imperial Institute, London, S.W.7.

Metallurgist—The Secretary, British Non-Ferrous Metals Research Association, 81–91 Euston Street, London, N.W.1.

FREEDOM IN THE GOOD SOCIETY

WHATEVER may be the outcome of the proceedings of the Commission on Human Rights of the Economic and Social Council of the United Nations meeting at Geneva, the very existence of that Commission is a reminder of the many threats to human freedom which beset the world to-day. Mr. Bevin's recent speech, focusing sharply the rift between the U.S.S.R. and Western Europe, indicated that to some extent it is due to the different views of human rights arising from the different emphasis placed on the community and the individual. Again and again the events he surveyed testified to the truth that tolerance and respect for human personality are not only the essence of democracy but also the essence of civilization itself.

The issue of freedom in political affairs is closely related to the issue of freedom in science. Even on this question of tolerance, it has been emphasized in recent discussions on operational research how important are the contributions which minority groups or individuals have made in developing views opposed to the accepted or orthodox opinions of the majority; and the dangers which secrecy in research offers to the advance of science have been made abundantly plain in the debate on the control of atomic energy.

Nor is this all. As the debate in the House of Commons on the Atomic Energy Act of 1946 revealed, the fundamental problem is the extent to which powers of control shall be entrusted to the Government, and the way in which those powers are exercised. It is a problem in government, above all a problem in democracy; and it is a disturbing reflexion that, in one sphere after another, even in democratic Britain, controls have been imposed and administered in ways likely to impair respect for human personality and to arouse the opposition rather than to secure the consent of the governed. In its handling of the fuel crisis, the petrol situation, the new health service and the question of a wages policy, the Government has used too often the methods of the totalitarian State rather than those of a democracy; and under the forms of parliamentary government has shown a spirit of intransigence which, as Sir Ernest Barker points out, is fundamentally opposed to the spirit and temper of accommodation which is the touchstone of democracy.

In his recent book, "Science and Freedom"*, Dr. Lyman Bryson says that when a decision he could make for himself is taken out of the hands of a citizen, his government has failed in democratic operation. That observation is highly significant in regard to the threats to freedom just indicated, and especially in regard to the question of the structure of the public corporations which the programme of nationalization in Britain has brought into prominence and made so urgent and vital. Equally pertinent reading to-day are those general principles and recommendations based on experience at a Japanese re-location camp which Lieut.-Commander A. H.

---

* Science and Freedom. By Lyman Bryson. Pp. xi+191. (New York: Columbia University Press; London: Oxford University Press, 1947.) 15s. net.

Leighton has embodied in his book "The Governing of Men"*. In both books there is much to be pondered by all who are concerned in any way with problems of human freedom, and with the urgent question of developing institutions in which those needs can best be served both in the field of science and in those of social, economic and international affairs.

Dr. Leighton places his first emphasis on the need for great understanding on the part of an administration faced with a community under stress. That, rather than great remedial change, is the important factor; and there could scarcely be a more severe indictment of both the great political parties of Britain during the past three years. Then he suggests that an administration should select means that are readily workable, not only in terms of the causes of the stress but also in terms of the way people are reacting, in terms of their habitual attitudes and beliefs, and in terms of their customary forms for dealing with each other. The channels of assent can never be dug too deep, whether we are concerned with legislative or administrative action. Here Dr. Leighton emphasizes the difference between human or social engineering and engineering in the mechanical or physical sense. Not merely does he point out that no alteration of policy should be arbitrary, and that what alterations are chosen should be carefully explained so that those concerned recognize their advisability, but equally he reminds us that administrators should not be too afraid of admitting they have been in error.

Dr. Leighton's fourth conclusion that, wherever possible, plans for social change should be tried out first on a small scale in a segment of the community, and also his fifth, that the administration must identify and deal with the basic social units of the communities, are in line with the results of the researches which Dr. Elton Mayo expounds as the basis of his work "The Human Problems of an Industrial Civilization". Nor can it be charged against Dr. Leighton that he is too conservative; for in his sixth conclusion he recognizes the opportunities which a time of stress affords a skilful administration for guiding constructive developments and even securing extensive changes which might be impossible or extremely difficult in normal times.

What pervades the remaining four of his conclusions most strikingly is the emphasis placed on the need, already indicated, for securing the consent of the governed. The great promise he holds for men and their government is in a fusion of administration and science to form a common body of thought and action, realistic both in dealing with everyday needs and in discovery and improved practice.

Dr. Bryson's book is essentially an essay on the theme that the scientific method can be used to understand human behaviour, and that scientific knowledge can be applied to the management of human affairs. He would use social engineering to solve the problem of setting up the conditions of freedom, but not to determine what men shall do with freedom when they get it. His thesis is that science can be used as one of the tools by which to establish the conditions in which human powers may realize human values. He believes that the conditions of freedom are the conditions in which the creative powers of man, and all the other creative factors of Nature to which man has access, can work best; and he suggests that if we can inspire the behaviour of man with a real desire for freedom and creative change, we can build social structures that will make creative change not violent and costly but peaceful.

Dr. Bryson recognizes that the social structures of a free society are complex, and he insists that our primary concern should be with the condition and techniques of freedom—the content of freedom rather than the use men make of freedom. Once again we find the emphasis laid on the educational aspect of the process of government, on the dangers of centralization of power and the revolutionary character in this context of the conception of economic democracy as it applies to the trade unions and to the employer or manager. Dr. Bryson insists, however, that economic democracy must have political democracy as its counterpart, and he suggests further that this conception of freedom will only be served when to these we have added what may be termed a democracy of culture, where creative genius will have its fullest scope to serve mankind. Just as he defines the conditions of freedom for the person as those that give full use to his creative powers, so he defines the free society as the creative society.

It is important to remember social science has external limits, as well as its internal imperfections. If we are to persuade men to make the effort involved in the scientific solution of human problems, we must, as Dr. Bryson rightly points out, not only meet the criticism that objective thinking has thus far done little to make human behaviour better by any rational standard, but also combat the widespread belief that science is wholly materialistic, deterministic and inhumane. In his succeeding chapters, and notably in that on education, Dr. Bryson gives some indication of his ideas as to how that is to be achieved.

The deeper habits of thought of the philosopher might well, as Dr. Bryson implies, have helped governments to avoid some of the disastrous mistakes of recent years if only by emphasizing the way in which, as each action is taken, the whole situation is more or less changed at the same time. He gives us a glimpse of the dangers of propaganda and of the possibilities in the right use of persuasion where freedom and personality are respected. In his final view of the good society, he once again insists on the necessity for the greatest possible diversity of institutions and chances for loyal attachment; and for the opportunity for the members of the good society to change their own individual patterns of loyalties, shifting from one institutional group to another not only at a time when the whole culture is changing but even with the idiosyncrasy of personal experience.

Whether or not we accept the whole of Dr. Bryson's argument, he has given as suggestive and stimulating a contribution to the whole question of freedom and order, of the relations between science and power, government and the individual, as Dr. Leighton has done in analysing his experiences in the re-location camp. They do not, it is true, take us a great deal further than Sir Ernest Barker did in his "Reflections on Government", though Dr. Leighton at least can quote evidence of the way in which a scientific approach has made a real contribution to the problem of governing men, and with the same success as attended the investigation at the Hawthorne Works of the Western Electric Company described by Dr. Elton Mayo and Dr. T. N. Whitehead. Dr. Bryson goes further towards providing the philosophical basis which Dr. Leighton equally recognizes as essential.

---

* The Governing of Men. By A. H. Leighton. Pp. xvi+404. (Princeton: Princeton University Press, 1945.)

Most impressive of all, both books largely corroborate the truths which Sir Ernest Barker brought out and which more recently have been so brilliantly stated by Prof. R. M. MacIver in "The Web of Government"*. There is, indeed, grave peril when government usurps control over the myths of the community, especially since government is now armed with powers more formidable than it ever possessed before, against which democracy is the only safeguard; though, as MacIver points out, not an infallible safeguard, because people can be beguiled by propaganda along specious paths that lead to the end of democracy.

MacIver's lucid study displays two broad principles the full acceptance of which is essential if democracy is to endure. "One is that government should never be suffered to impose its controls on the cultural life of the community, to curtail the freedom of men to differ in their faiths and opinions, in their ways of thought and their ways of life, save when in the pursuit of these ways they inflict overt and objective demonstrable hurt on their fellow men. The second is a corollary of the first. It is that government should not be entrusted with so exclusive a monopoly over the economic utilitarian system that the implantation of these functions conveys with it the effective indirect domination of the cultural life. For if the life-chances, the very livelihood of individuals and groups are at the disposition of government, then the particular values and ideologies of the particular government will inevitably become absolute and will inflexibly impose themselves on the whole community, crushing its free spirit."

Some apprehension of this second precept may well be subconsciously behind the present concern of the medical profession in Britain over the National Health Service; but Prof. MacIver is right to hold that only by vigilant adherence to both these precepts can the peoples remain free and still breathe the life-giving air that comes beyond the realm of government. The relation between the advancement of science and political climate could scarcely be expressed better.

A recent forthright series of articles, "The Middle Class", appearing in *The Economist*, is also worthy of careful consideration. Under that title the position of the professional man is subjected to acute analysis, and there are many sound comments which the scientific worker in particular will appreciate. It was time that it was emphasized so bluntly that essential conditions of freedom for creative work in professional life are leisure, privacy, and the opportunity of external contacts: for high intellectual activity they are as essential as extra rations are to heavy manual labour. Sacrifice of such conditions is from the national point of view much the most serious consequence of the salaried classes losing ground out of all proportion to the general fall in national wealth, as compared with the wage-earner and the profit-maker; but it is a long way from being understood either by the Government or by many of the electorate. Neither is the civic, cultural or social *raison d'être* for the survival of the professional core of the middle class any more widely appreciated; and there are plain words indeed on the subject of experts without power in the third of these articles, which should be marked and heeded by every thoughtful and independent citizen.

It matters greatly how freedom and order are combined, and *The Economist* in this article points out that under present conditions the party system is giving us the worst of both worlds and that persistence in present tendencies in this era of social and economic engineering may have disastrous consequences. Both major political parties in Britain are hopelessly handicapped, and can be relied upon to paralyse their skilled administrators with political directives which frustrate purpose or nullify freedom. "So long as the professional class are merely instrumental in putting badly conceived plans into practice, their specific qualities will be wasted. And waste will continue until they are given a role in the framing as well as in the application of policy."

That is a challenge as well as a warning. National recovery and the large schemes of nationalization now being pressed forward in Britain will only succeed if we eliminate political bias and utilize to the full the principles and techniques of good management and sound administration. Self-interest, as well as his responsibilities as citizen, summon the scientific worker to play his part in establishing those conditions. For him this issue of freedom and order, on which the survival, not only of Britain but also of Western Europe, depends, is inseparable from the conditions for scientific advance; and the cultivation of intellectual freedom is itself a condition of the right and wise use of power.

STORY OF HUMAN EVOLUTION

Mankind So Far

By Asst. Prof. William Howells. (American Museum of Natural History Science Series.) Pp. xii+319+7 plates. (London: Sigma Books, Ltd., 1947.) 16s. net.

THE ignorance of otherwise well-educated people concerning the origin of their own species is not a little astonishing, considering the personal nature of this problem and its intimate relation to philosophical concepts of human existence. One of the reasons for this apparent apathy, no doubt, is the meagreness (until quite recently) of the direct evidence of the fossil record. Another is the difficulty which anthropologists so often seem to experience in making their field of study intelligible to the general public.

The first reason scarcely obtains any longer, for the discoveries of the last few years have filled in some of the gaps in the palæontological sequence in a most remarkable way. Now the second difficulty has been shown to be surmountable, for Dr. Howells, in his popular book "Mankind So Far", has not only adopted a style which is eminently readable (not to say entertaining), but has also managed to provide a great deal of important information without assuming any specialized knowledge on the part of the reader. His style is the conversational style of the accomplished popular lecturer, transferred directly into writing without any re-casting or re-phrasing to make it conform to the traditional method of presentation which is so commonly associated with the 'science manual'. The result is extraordinarily successful. For one thing, it makes the subject appear to the ordinary reader as exciting as it really is to the specialist. For another, it serves to emphasize that the science of human evolution (like other sciences) is nothing more than organised common sense and, as such, can be readily comprehended by the non-specialist. But it has yet another advantage. By reducing arguments which have from time to time been advanced for this or that partisan theory of human evolution from 'academic' phraseology to ordinary conversational style, the author has at the same time reduced them to their proper proportions, and sometimes, it must be confessed, has even shown them to be slightly ridiculous.

Dr. Howells' exposition of the study of human evolution is permeated by a robust common sense and by a welcome sense of humour which seems by no means out of place when he deals with controversies which, in more academic circles, have been conducted with unnecessary acrimony. We would particularly commend his illustrations, which are simple and direct and yet have obviously been carefully planned to clarify and emphasize his arguments with the maximum effect. They certainly achieve their purpose. The student who aspires to a mastery of human palæontology may be well advised to use this book as an introductory study.

MATHEMATICS IN INDIA

Ancient Indian Mathematics and Vedha

By Prof. L. V. Gurjar. Pp. vi+202. (Poona: Ideal Book Service, 1947.) 6.4 rupees; 10*s*.

FOR too long the history of mathematics in India was studied only by scholars suffering under the almost insuperable handicap of belonging to an alien civilization; but recently a number of Indian mathematicians have made a welcome appearance in this appropriate field. Prof. Gurjar's little book on mathematics up to the twelfth century and on pre-telescopic astronomical instruments is full of interesting material, but its tone is altogether deplorable.

European scholars began to study the mathematical classics of India a long time ago—Colebrooke's translation of the "Lilavati" was published in 1817—and no help from Indians was forthcoming; the language was dead as well as foreign, the background had to be inferred, the idiom was enigmatical, and these pioneers made some of the mistakes which Prof. Gurjar would make if he attempted to translate "The Crafte of Nombrynge" or Chaucer's "Astrolabe" from imperfect contemporary manuscripts and was unable to find one Englishman competent to discuss his difficulties with him. Nor did the Europeans approach their task without taking for granted that the history of mathematics in India would fit into the story of mankind as they knew it: there was a road from Athens to Bologna and Paris and Oxford through Alexandria and Baghdad, and if mathematics was found to have been cultivated in medieval India, there must be another road from Greece to be traced.

Prof. Gurjar has still to learn to correct what he believes to be a mistake without jeering at it, and to challenge an assumption without resenting it as a deliberate insult to his people. To traduce scholars no less honest than himself is no way to impart a sense of confidence in his own interpretations of ancient texts. At the end of his account of Bhâskarâcârya's work on indeterminate equations, he writes: "To deny the due credit and the honour to the Hindus, is a sheer obstinacy which only the prejudiced Western scholars are capable of having". But what, in fact, did Cajori, of whom Prof. Gurjar complains again and again, write in 1894? "The perversity of fate has willed it, that the equation . . . should now be called *Pell's* problem, while in recognition of Brahmin scholarship it ought to be called the 'Hindoo problem'. It is a problem that has exercised the highest faculties of some of our greatest modern analysts. By them the work of the Hindoos was done over again." And on another page: "It is remarkable to what extent Indian mathematics enters into the science of our time. Both the form and the spirit of the arithmetic and algebra of modern times are essentially Indian and not Grecian." This is the very language that Prof. Gurjar wants us to use. Cajori, it is pertinent to observe, is not an orientalist drawing conclusions from his own discoveries; he is a historian reducing to the scale required for a comprehensive work the cumulative judgment of the actual investigators. Nevertheless, Prof. Gurjar roundly accuses the Western scholars, with the explicit exception of Hankel, of "hesitatin to record the credit to the Indians simply becaus they are Indians".

A protest must be made. Burton was warnin the British a century ago to be under no illusion as to the feelings of Indians towards them. Th mathematicians of Britain bear as citizens their shar of responsibility for their country's failures, but the can claim that as mathematicians they have consistently offered not patronage and generosit but appreciation and partnership; the names o Mukhopadhyay and Paranjpye and Rajan, o Naraniengar and Prasad and Vaidianathaswami an a score of others, as well as the great name o Ramanujan, have been honoured equally at Cambridge and in their own land. Surely we have earne the right to expect from Indian mathematicians a this critical moment that whoever else prepares fc the future in terms of hatred, they at least will prc claim the reality of interdependence, and the poss bility of mutual respect and ultimate friendship. Th nursing of grievances has perhaps caused more miser than any other uncivilized habit of mankind; to ad one untrue word to the tragic tale of past wrongs i wanton mischief, and to create a legend of injustic is an infamy.

E. H. NEVILLE

'PLASTHETICS'

The British International Plastics Annual, 1947

Pp. 274 + 183. (London: Croome Hill International, Ltd., 1947.) 63*s*.

THIS work is designed for that large body of users of plastics who require a central source of information on the varied aspects of the industry. It provides technical data on the materials available commercially, and practical advice on the machinery and technique in their treatment. For the present, the authors are only concerned with developments in the British Commonwealth and the United States, so that this volume bears the title "British International Plastics Annual". Later they visualize a true international plastics annual published in many countries and in many languages but identical in matter. A system of standardization is thus essential, and this is one of the objects the Annual sets out to achieve.

The book deals with all modern plastic materials, and these are laboratory-synthesized resins and plastic products from 'Acrylic to Zein'. The authors introduce the descriptive word '*Plasthetics*' (derived from *plas*tics, syn*thetics*) to cover these products.

An introduction to organic chemistry, colloids and analysis is followed by a general description of the main groups of plasthetics, which number about thirty types. The properties of synthetic plastics are treated under general, physical, mechanical, optical and electrical properties, the effect of chemicals and finally the standards of the American Society for Testing Materials. In the section on fabrication processes we find compression, transfer, jet and injection moulding, as well as the manufacture of laminates, foil and sheet. There is also a useful section on diathermic and infra-red heating. The miscellaneous applications of plastics are very varied, and include varnishes, lacquers, yarns, safety glass, printing and adhesives, also medical and biological uses.

A comprehensive directory section gives technical data on upwards of eight hundred British and American commercial grades of plastics, machinery and equipment, together with the characteristics of two hundred solvents and plasticizers. This section includes the societies, trade associations and educational facilities in the plastics industries.

A work of this kind in its first issue can scarcely hope to be free from blemishes, and the publishers provide a questionnaire asking for comments and constructive criticism. Certain criticisms are noted by the reviewer. The index is not adequate for finding the extensive information provided. Some organic formulæ require correction, for example, the breakdown of naphthalene (p. 20). The COOH and other groups are sometimes built into the aromatic ring (for example, in the phthalic acids, p. 114) when they are only substituents. The sensitization of colloidal gold by gelatine (p. 29) is rather out of place, and emphasis on its protective action would have been more to the point. Some of the formulæ for mechanical properties (pp. 144–153) require revision and correction, and the symbols should be those used in current practice by engineers.

Such criticisms, however, are of a minor character compared with the major qualities of this work. This Annual should be of great value to the members of the industrial world for whom it is intended. It is probable, however, that a wider range of readers will be eager to possess copies so far as the limited supplies will allow. The production of the book is of a high standard. Its useful contents, added to clear printing, good binding, and general appearance, will make it a worthy ambassador for British enterprise in the countries which it may ultimately reach.

S. R. CARTER

TEXTILE FIBRES

Matthews' Textile Fibers: their Physical, Microscopical and Chemical Properties

Fifth edition, prepared by a Staff of Specialists under the editorship of Herbert R. Mauersberger. Pp. xvi + 1133. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 75*s*. net.

THE conversion of fibrous materials into cloth or felt has commanded the attention of civilized man from earliest times, and over the years a great deal of skill in the manipulation of a wide variety of naturally occurring fibres has been acquired. The existence of subtle differences between the various grades of fibres is well established, and the selection and blending of raw materials plays an important part in successful commercial processing. Prior to 1904, when the first edition of "Matthews" was published, most of the information on textile fibres was an accumulation of the observations of inquiring growers and industrialists; but in more recent times scientifically trained chemists, physicists and biologists have been attracted by the many problems involved in elucidating the structure of fibres and in investigating their physical and chemical properties. Great advances in our knowledge of the basic characteristics of textile fibres have resulted from work of this type, and there are now sufficient data available to justify a chemical interpretation of the fine structure of most fibrous materials. Probably the greatest contribution of the scientific worker to textiles has been, however, the development of the rayon industry to a size comparable with that of industries concerned with the natural fibres. New rayons with extremely interesting manufacturing possibilities have been introduced, and the day is not far distant when fibres will be made to precise specifications laid down by users.

This great expansion of activity in the field of textiles, and the consequent spate of original contributions, created a need for an authoritative publication collecting together most of the existing knowledge, and this has been met by the new and fifth edition of "Matthews"—the result of a united effort by some forty-seven experts. The work has been carried out under the general direction of H. R. Mauersberger, who is a well-known editor of textile publications, and his collaborators include eminent specialists such as K. R. Fox, F. C. Atwood, P. Larose, R. F. Nickerson, E. R. Schwarz, W. A. Sisson, H. DeWitt Smith, and W. von Bergen.

Detailed accounts of the production and properties of both natural and man-made fibres are given, together with descriptions of lesser-known brush, cordage and fur fibres, and there are chapters on fibre testing and fibre identification. Although due emphasis is given to microscopical characteristics, physical and chemical properties, and research concerned with the study of fibre structure, the results of more technical investigations are not neglected. Thus data on the statistics of fibre production and details of the characteristics of the many commercial grades of each type of fibre are included. It is perhaps inevitable that stress is laid on American research and practice, although reference is made to many British papers.

The book is extremely well written and presented; the illustrations are good, the printing very clear, and the binding and quality of paper are such as to make most English authors envious. All who are interested in textiles, whether they are research workers, manufacturers, salesmen, directors, teachers or students should find this volume particularly valuable, for it is probably the most important publication on textiles which has appeared in the last twenty years. The authors are to be congratulated on their achievement. C. S. Whewell

ELECTRONICS IN INDUSTRY

Electronics for Industry

By W. I. Bendz, with the assistance of C. A. Scarlott. Pp. x+501. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 5 dollars.

THE purpose of this book is to introduce the engineer who has had no special training in electronics to the fundamental principles involved in them, and the means of their practical application. The latter include a very wide range: photo-electric devices, high-power rectifiers, high-frequency heating, and various types of control circuits. The diagrams are mostly basic circuits illustrating the methods used, and so are not confused by minor details, though some actual circuits are given.

On the theoretical side, the book opens with a very clear introduction to as much of modern atomic physics as is necessary for the understanding of the action of practical electronic devices; this is material on which the average engineer is often sadly deficient.

The characteristics of the various types of valves are then dealt with, particular attention being given to the form of discharge in gas-filled valves, and there are many illustrations of actual electrode systems. The nomenclature throughout is the American standard, which differs from that in use in Britain; but the meaning of each expression is fully defined. Attention is then given to rectifiers of all types, from the small power pack for ordinary valve circuits up to the high-power three-phase mercury vapour type, with constructional details of the latter. Considerable attention is given to various types of firing circuits; but distortion of wave form is only slightly dealt with. In the chapter on amplification the basic principles are clearly dealt with, the work being entirely confined to medium-frequency working, no reference being made to the special difficulties which arise with high- and ultra-high-frequency working. A chapter on oscillators follows, all the normal circuits including dynatron and beat-frequency circuits being given, as well as a short description of the piezo-electric crystal.

After a short chapter on modulated signals, the rest of the book is given up to the description (including circuit diagrams) of all types of commercial electronic applications, classified under various headings: and this part contains much information which, up to the present, has been difficult to get in collected form without reference to specialized papers.

Taken as a whole, the book should be of great value to the user of electronic devices; it is not intended for those who have to design them, though throughout there are many references to more detailed information, including a bibliography at the end of each chapter. J. Hollingworth

ATOMS FOR THE LAYMAN

The Atom and its Energy

By Prof. E. N. da C. Andrade. Pp. xii+196+12 plates. (London: G. Bell and Sons, Ltd., 1947.) 10*s*. net.

Meet the Atoms

A Popular Guide to Modern Physics. By O. R. Frisch. Pp. xiv+226. (London: Sigma Books, Ltd., 1947.) 12*s*. 6*d*. net.

PROF. ANDRADE is an old hand at explaining the mysteries of atomic structure; his "Structure of the Atom" was the standard text in the days when electrons circulated on nicely calculable orbits around the nuclei that Nature provided for our study. The electrons have long since abandoned their tram-way-like orbits and, like buses in a fog, have a mere probability of being somewhere near a given route; new kinds of nuclei can be manufactured at will in great variety; and we have learned how to use, or misuse, the immense energy of nuclear forces.

In "The Atom and its Energy", Prof. Andrade marshals the modern array of atomic facts and theories with his usual skill, illuminates them by ingenious analogies, and spices the dish with a literary flavour; though the reviewer's metaphors may be mixed, the author's are not, and they magnify the atoms to visible size with amazingly little distortion.

Prof. Frisch, in "Meet the Atoms", follows the more informal plan of taking the reader into the laboratory and explaining how experiments in nuclear physics are devised, performed and interpreted. The apparatus is there, real and life-sized, and there is no need to magnify it; but when an analogy can help in interpreting the observations, Prof. Frisch does not hesitate. For example, he compares the dual wave and particle aspects of light to the appearance of an animal that everyone's right eye sees as a dog and everyone's left eye sees as a cat; he remarks that in time we would get used to this and would cease to worry about which it 'really was'. Such analogies, crude though they may be, are in harmony with the atmosphere of a real laboratory, where the apparatus and the conversation are not always highly polished. Prof. Andrade's book belongs rather more to the study, and has both gained and lost by its slight detachment from laboratory details.

The cat-and-dog analogy does not apply to this pair of books; each author sees the atoms clearly with both eyes, and explains them to the reader in his own way. The books are not, of course, written for the expert, but they will hold the interest of physicists as well as of the less-specialized public for whom they are intended. They are books about atoms and not primarily about atomic energy; Prof. Frisch deliberately says very little about that subject, and Prof. Andrade is not at his best when dealing with its technical and scientific aspects, though his comments on the moral and political issues show the clear thinking and fine writing that we expect from him. P. B. Moon

Microdiffusion Analysis and Volumetric Error

By Prof. Edward J. Conway. Revised edition. Pp. xix+357. (London: Crosby Lockwood and Son, Ltd., 1947.) 21*s*. net.

MICRO-DIFFUSION analysis represents a real advance in modern analytical technique. It seems strange, in fact, that the underlying principle of allowing the gaseous product of a reaction to diffuse, in a closed chamber, into a suitable absorbent or reactant should not have been used more extensively in analytical procedures at a much earlier date. Absorption of gases into appropriate reactants by distillation and aeration methods is, of course, the basis of many well-known, and important, chemical and biochemical methods of analysis, but the methods are usually tedious and extravagant in apparatus and material. Conway's technique involves the use of a simple and inexpensive glass apparatus (termed the 'Unit') consisting of an inner and outer chamber. The gaseous product of a reaction (for example, ammonia, volatile amines, carbon dioxide, acetaldehyde) passes from one chamber, where the gas exerts a certain tension, into an absorbent in the second chamber, where the tension approaches zero. Analyses are made of the contents of the second chamber, and the accuracy is limited only by the accuracy of delivering and titrating fluid volumes of the order of 1 ml. Conway claims that the method appears to be the "simplest possible consistent with the maximum attainable accuracy in the handling of micro-volumes". The technique has been adopted for analyses of ammonia, amides and amines, adenosine and adenosine derivatives, halogens, alcohol, acetone, lactic acid and glucose, carbon monoxide and carbon dioxide. It may be used also in the estimations of enzyme activities.

Conway's book describes his 'Unit', the various physico-chemical factors involved in diffusion techniques, the micro-pipettes and burettes required and the errors involved in their use. It gives details of the analytical methods involving the micro-diffusion technique which have now been adopted in many laboratories, and it has a most valuable section on the errors encountered in volumetric titrations. It has a good bibliography, and is well illustrated and produced. It is a book which should be in the hands of most biochemists and clinicians.

Archæology and Society

By Grahame Clark. Second edition, revised. Pp. xv+222+24 plates. (London: Methuen and Co., Ltd., 1947.) 10*s*. 6*d*. net.

THIS is a welcome new edition of a book which in October 1939 found a rapid sale, and should certainly do so now. It is one of the best and most readable short introductions to archæology in general, and though much in it has needed no revision, Dr. Clark has related his themes to their present-day setting with sound judgment. Archæology studies how men lived in the past: in partnership with documentary history if available, but in any event with confidence that it can do much that its partner cannot, in particular, of course, in the study of prehistoric times. This does not make it in itself altogether a science; yet it owes its modern precision largely to its growing capacity to collaborate with natural sciences, in the application of their techniques to the study of man's past doings. In that matter Dr. Clark at Cambridge has himself long been a leader, and this gives especial value here to his chapters on archæological discovery, preservation, excavation and chronology. Finally, too, he gives us some excellent plain speaking on the all-important 'social relations' of his subject: research must be kept free of perversion by nationalism, and devoted to the honest pursuit of historical truth.

C. F. C. HAWKES

Faraday's Encyclopedia of Hydrocarbon Compounds

(Covering the Literature up to January 1st, 1947). Compiled by Dr. Joseph Escott Faraday. Vol. 4: C_9 Pp. lxxxviii+448. (Manchester: Chemindex, Ltd., 1947.) £5 10*s*.

DR. FARADAY, in accord with his promise, now presents us with volume 4 of his encyclopædia of hydrocarbons; the author and his publishers are to be heartily commended on being able to keep such a promise in these difficult times. The present volume deals with the C_9 compounds up to January 1, 1947, and follows closely the lines of the previous parts, now so well known to organic chemists.

It is stated in the foreword that future volumes will contain the Dyson cipher of the compounds described: this will greatly increase the value of the work if and when the Dyson cipher becomes widely used.

It came as a slight surprise to the reviewer to find indane called 1 : 2-trimethylane-benzene, and indene, 1 : 2-trimethylene-(7)-benzene; on reflexion, this possibly appears logical, but it will surely be some time before 1 : 3-tribromopropane is called trimethylane dibromide, and surely the group $>CH_2$ is methylene, although perhaps this term should be reserved for $=CH_2$. Hydrindane, which might be expected to be 1 : 2-trimethylane-*cyclo*hexane, is bicyclo-hexane-(1,2)-pentane.

The reviewer is, of course, well aware of the difficulties of systematic nomenclature, and the above remarks cannot be taken as adverse criticism.

The Yearbook of the Universities of the Empire, 1947

Published for the Universities Bureau of the British Empire. Pp. xxxi+1098. (London: G. Bell and Sons, Ltd., 1947.) 21*s*. net.

THE usefulness of this valuable reference book is attested by the sorry condition to which the last issue, that dated 1940, must have been reduced in any institution or department in touch with university affairs. The war-time Supplement issued in 1941 carried on the information for but a short space, and it has been necessary to wait six years before the complete data relating to the staffs of the universities of the British Empire could be made available once more. Even now, due to the rapid expansion taking place in the universities themselves, and also to the longer time now required for printing such a book, it is not claimed that the information is up to date in the sense it used to be. The new volume contains about a hundred pages more than that for 1940—an indication of the growth of the universities that has taken place.

As before, the information under each university includes a directory of the officers and staff, general information and reports of events of outstanding interest during the previous year. There are appendixes on the qualifications for admission to a first degree, statistics of foreign students in British universities, general conditions in American universities, and Anglo-American professorships.

OPERATIONAL RESEARCH IN THE RESEARCH ASSOCIATIONS

WHAT is 'operational research' ? Is it an activity of major importance to industry ? Can it be carried out effectively by co-operative organisations such as research associations ? How does one set about organising operational research ? These questions were examined at a conference on January 13 and 14 attended by representatives of most of the research associations and of a number of establishments of the Department of Scientific and Industrial Research. The conference was organised by the Committee of Directors of Research Associations under the chairmanship of Mr. B. H. Wilsdon, and was held at Ashorne Hill, through the courtesy of the British Iron and Steel Federation. The conference showed that it was possible to make a reasonably clear definition of the subject, and that operational research in one form or another had proceeded with growing emphasis in certain of the research associations very successfully for a considerable number of years. The research associations generally find themselves very suitably placed for an extension of this type of activity, in view of the wideness of the fields they survey and the close contacts they have with the executives in the industries they serve.

It was desirable to obtain first a general form of words and then to follow this by a consideration of the various factors that make up what might be called 'Operational Research'. The discussion was opened by Sir Charles Goodeve, who proposed a definition based on that put forward originally by Dr. Charles Kittel[1]. After some discussion, the following amended form was considered accurate enough for most purposes :

Operational Research is the use of the *scientific method* in providing executive departments with a *quantitative basis for decisions* regarding the *operations* under their control.

The most problematical part of the definition was in the scope associated with the word 'operations'. In general, it was considered desirable to keep this scope as wide as possible, ranging from the operations in ordinary production engineering to policy matters associated with consumer needs, national economic positions, etc. The chief difficulty appeared to be in drawing a line between process or equipment research and operational research, and it was clear that any attempt to draw a sharp line would be artificial and probably harmful. The difference between 'process' and 'operational' research comes down largely to one of direction of approach. The operational research worker starts with the overall picture and may study individual processes in relation to the whole picture, whereas the process research worker is more concerned with developing certain processes to the highest pitch of efficiency in relation to other parallel or following processes. In addition, there is a difference in degree in that the operational research worker more often has to rely on observations of happenings over which he has no control, whereas the process research worker can generally carry out deliberate experiments with at least a substantial degree of physical control. The operational research worker much more frequently has to deal with human factors, market conditions and the many other factors troubling men in executive positions.

Dr. F. C. Toy, director of the British Cotton Industry Research Association, which organisation has undoubtedly been among the pioneers in this type of work, opened the second session of the conference. He said that, judging by his own experience, operational research should form an integral part of the activities of a research association. It can obtain a comprehensive picture for the whole industry by a collection of data from individual firms, which can be summarized by a statistical digest and a general report. By feeding back this digest to all firms, together with a special confidential report to each individual firm, the executives concerned can see their own position in the light of a complete and accurate background. These reports often act simply by stimulating managers to look again at problems or deficiencies already known to exist. This method has proved to be a much quicker way of improving efficiency than the old one of waiting for economic factors to bring into successful prominence the more efficient plants. These studies can also bring out quantitative information on the factors affecting an industry as a whole, and thus aid in determining the right policies for the industry. This is an especially important point in these days when the Government has to deal with many contending issues.

Dr. Toy discussed the prospects of operational research being carried out by organisations other than research associations. Individual firms and professional industrial consultants are limited to studies inside the confine of a particular works ; but they can obviously be helped by the wider picture provided by the research associations. The universities and technical colleges are unsuitable for this type of work, but they play a major part in training personnel. The trade federations have a wide picture of the commercial side of each industry; but their lack of technical knowledge and of scientific atmosphere puts a severe limitation on their activities. However, research associations should work in closely with the trade federations, since many of the executive decisions have to be made by such bodies. There may be special instances where operational research should be carried out in industry by Government teams; but if this is done widely in industries served by research associations, it means duplication of effort. In addition, managements are more ready to co-operate with people in an organisation belonging to their own industry than with those who may be looked upon as Government investigators.

All these arguments supported Dr. Toy's contention that, because of the scientific atmosphere, complete impartiality, close contact with industry, with other research organisations and with Government departments, and because of the confidence placed in them by management and operatives, the research associations are the most suitable bodies to carry out operational research in industry.

Mr. A. T. Green, director of the British Ceramics Research Association, pointed out that operational research methods are of particular value in the older industries where the processes are based on traditional methods developed by subsequent experience. He referred to the detailed works surveys carried out for the National Brick Advisory Council. These give valuable indications of the labour used and of the minimum requirements under a wide variety of manufacturing conditions.

Dr. S. Whitehead, director of the British Electrica and Allied Industries Research Association, spoke about operational research in fields ranging from high-power transmission to radio interference, and emphasized that operational studies frequently pro vide certain links in a chain of deduction of which the remainder are supplied by science and engineering.

Mr. H. Bradley, director of the British Boot, Shoe and Allied Trades Research Association, described the extensive surveys made into the fittings of shoes, based on analyses of measurements of some thousands of feet. For example, most factory-made women's shoes are produced in what are known as single-fitting ranges, that is, each size or half-size of length is made in only one girth. It has always been the practice in the industry to add ¼ in. in girth for each successive size. How this interval was arrived at nobody knows, and the analyses of foot measurements showed the correct interval to be 3/20 in.; or 40 per cent less. The practical effect of this on the fitting properties of shoes, particularly the extreme sizes, is considerable, and the Research Association's 'precision grading' based on the new girth interval is having great commercial success.

Mr. D. J. Bishop, of the British Iron and Steel Research Association, showed how a large part of the research programme of that Research Association is continually under study by the operational research team with the object of providing those concerned with the framing of that programme with adequate information, so that research can be focused on problems the solution of which is likely to produce the greatest economic advantage to the steel industry. This is a case where operational research is used at a 'strategic level' to guide research policy.

It was clear from the points raised by numerous speakers that, despite the large volume of operational research already proceeding in industry in Great Britain, many obstacles would have to be overcome before the desired wide application could be attained. In some industries, the firms' problems are so diverse that wide approaches or comparisons are of little value. Also, some industries have been built up and owe their strength to keen competition between firms. Mr. Wilsdon pointed out that, in operational research *within* an industry, it is essential to take into account variation in the quality of the product, which must be associated in some way with the expenditure of energy in the operations studied in order to provide a comparable basis for executive decisions. Thus criteria such as operations per man-hour or the like might be positively dangerous unless there are good grounds for assuming that the quality of the product is the same throughout. It is clear, therefore, that different industries are likely to adopt operational research to different extents.

On the other hand, as was pointed out by various speakers, there never has been a more favourable opportunity for an extension of operational research. With the present 'sellers' market', competition is at a minimum and co-operation at a maximum. Organised labour, which has always had to look first for security of employment, is able now to take a broader view and consider efficiency of employment.

The discussion on organisation and staff was opened by Mr. Tippett, of the British Cotton Industry Research Association. He considered that a separate operational research team is desirable if the subject is to be treated with the seriousness and comprehensiveness its importance requires. The separate team requires close contact with the management side of ndustry, with the trade associations, Government departments, etc., and also should have close conact with the field observational work. The team should be staffed with men chosen first of all for their ability to view things widely. They should have good scientific ability, and need to acquire technical knowledge of the industry they serve; but they need not have any particular specialized qualifications. The knowledge of statistics required for most of the work is not very great, although it is desirable to have at least one first-class statistician in a team. It is very important that members of the operational research team should be able to talk to managers, foremen and operators, and to get on well with everyone in the factory.

The objects of operational research which have been or could be carried out by the research associations can be summarized as follows: (1) to increase production per man hour, per unit of equipment, or per unit of fuel; (2) to improve quality and suitability of products; (3) to improve the basis for decisions regarding the application of science ('bridging the gap'); (4) to make accurate studies of consumer or market problems, that is, scientific studies in market research; (5) to aid in finding the optimum degree of standardization for any particular field of production; (6) to aid in the planning of research programmes.

The proceedings concluded by short talks by Dr. W. L. Francis, of the Department of Scientific and Industrial Research, and Dr. Alexander King, director of the scientific secretariat, Lord President's Office, on operational research activity and interest in Government departments.

FOOD PRODUCTION FROM HILL GRAZING LAND

By Dr. GEORGE DUNLOP
West of Scotland College of Agriculture

THE Minister of Agriculture has pointed out that while before the War, for Great Britain as a whole, less than 40 per cent of our food, on a calorie basis, was produced at home, this figure in 1946 had increased to almost 70 per cent.

The land of Scotland may be classified under the headings of:

(1) Farm land: arable and grass land.
(2) Hill pasture.
(3) Other land: deer forests, woodlands, etc.

Sir John Russell has estimated that one acre of farmland produces sufficient food for one person. The population of Scotland is about five million and the arable and grassland acreage about the same figure. This indicates that Scotland is self-supporting in food. It is true that tropical foods, such as grapefruit, bananas, etc., are imported; but on the other hand a good proportion of the arable acreage is devoted to the production of seed potatoes which are transported to England and abroad. Similarly, surplus milk on occasion has found a market south of the border.

The agricultural returns show that there are approximately ten million acres of hill land in Scotland devoted to hill sheep farming. The agricultural production of this type of land will be discussed later. The remaining four million acres may be classed, so far as agricultural production is concerned, as 'waste', and consists mostly of deer forests and woodlands, from which the agricultural productivity is practically nil.

The hill sheep grazings, which are found on more than half of the land of Scotland, produce, according to the Hill Sheep Farming Report[1], 1·4 million draft ewes and lambs which are sold in the autumn of each year. Most of these animals have to be fattened on arable pasture. Responsible livestock graders of the Ministry of Food estimate that the overall average carcase weight of these animals when drafted from the hill grazings is 30 lb. It is clear, therefore, that the hill grazings of Scotland produce 42 million lb. of mutton and 10 million lb. of wool on the average per year. For the five million people in the country, that half of Scotland devoted to sheep farming on hill grazings provides the equivalent of only four days supply of calories and protein yearly.

With the increasing urge for greater home production the question arises as to how the productivity of the hill grazings may be increased. At present given over to hill sheep farming, they are stocked almost solely by hill sheep. The basis of this system is the reduction of the stocking of the hills to the number of animals which the grazings can support during the winter months. The Hill Sheep Farming Report gives the number of ewes carried under these conditions as only 2¼ million on the 10 million acres of hill grazing.

The secretary of the National Sheep Breeders' Association has stated that seventy years ago there was a total of 30 million sheep in Great Britain as a whole, which number decreased continuously until 1920. In 1920 after the First World War there were only 20 million sheep in Britain. This figure increased up to 1940, when the number reached about 26 million, but after 1945–46 only 19 million remained. In 1947, largely as a result of the severe winter, the figure has dropped to a record low level of 16 million. "At no time in our history have we ever needed an increase in the supply of good British meat as we do now."

It appears unlikely that the 2¼ million breeding ewes at present carried on the hill grazings could be greatly increased under the hill sheep farming system even if the stocking was stepped up to what it was seventy years ago. It would scarcely double itself and it would appear, therefore, that any great increase of food production from grazings devoted to hill sheep farming should not be looked for.

The truth is that the productivity of the hill grazings is not reflected by the number of sheep sold each autumn. The sheep consume only a small part of the herbage produced on the grazings. Most of it is consumed by a fire which sweeps over the grazing every other spring-time. The herbage should be eaten off by animals and not burned off if productivity is to increase.

Research work has shown the inadvisability of grazing herbage constantly with one species of livestock. The internal and external parasites of the host animals increase in numbers until they become a serious menace. Many of the stock may actually die after years of decreased productivity on the grazing.

Furthermore, the amount of herbage produced per annum is greatly reduced owing to the constant grazing of the animals. Stocked as they have been for centuries to their full carrying capacity during the winter months, the spring flush of herbage, although still marked, has been greatly checked by the hard grazing in winter. Cattle are the species of livestock of choice which must return to the hills in much greater numbers than ever before. It is suggested that the hill land of Scotland be devoted principally to beef production or to dairying.

With the increase of home food production since the outbreak of the War, five herds of beef cattle of about a hundred breeding cows each have now been maintained throughout the year on grazings in West Perthshire since 1939. Although the acreage of grazing allotted to these animals is more than might be desired if maximum food production is the aim, it is interesting to note that the sheep stock has not decreased as many farmers appeared to expect, but has actually increased since the cattle were introduced. The animals remain on the hill all the year round but receive some fodder—straw or hay—from January until April. During this period the amount of herbage which is available on the grazing is very limited and the animals would probably fare much better if fed indoors. Their loss of condition during the early months of the year does not, however, appear to affect the calving percentage of the herd, which is the chief consideration. The progeny are taken off the hills in the autumn for fattening off on low ground.

The hill sheep farming system as practised at present on some of the grazings has been traced back to medieval times, when the chief consideration of the monks was wool production per abbey[2] and not maximum food production per acre. The whole object of 'hill farming' has changed in the interval.

After the 1947 experiences on hill grazings, it would appear that even the sheep stocks should be removed to lower ground from January and fed from the flush of herbage of the previous summer preserved either as hay, silage or dried grass. *All* grazings on hill land would benefit by at least two months rest in late February, March and April. It has been shown by Edinburgh parasitologists that large numbers of worm larvæ are picked up on the hill at this time and the mature worm burden rises to its maximum during June. It would appear that the food for the hill stock during the early months of the year should consist mainly of silage, hay or dried grass gathered from the previous summer flush of herbage on enclosed hill land. Recent experiences in Argyllshire and West Perthshire show that dairying can be conducted successfully on hill grazings, while the outdoor bail system has also proved successful in Morayshire and Fife. Ernest attempts should be made to extend the milk production of the country to hill land. A price incentive would be required and it is suggested that, after industry can supply all the equipment such as milking bails, material for covered courts, fencing, etc., dairying on arable land in Scotland should be discouraged and hill dairying encouraged by price regulation, say, 1*s*. 6*d*. per gallon for milk produced on arable land and 2*s*. 6*d*. per gallon for milk produced on hill land.

Such an enterprise, largely on hill land in West Perthshire, not only provided for the requirements of four local village communities but also exported milk to the industrial areas. On the other hand, Highland communities in proximity to which no dairying is practised obtain their milk supply from the arable and dairying areas of the Lowlands or from Ireland during the winter months. 'Milk from the Mountains' —the motto on the milk bottles of the Perthshire pioneers—would appear to be the policy for the hill grazings.

It was recommended by the Departmental Committee, appointed by the Secretary for Scotland in 1909, in its report on livestock and agriculture in the congested districts of the Highlands[3] that, where considered advisable, assistance be given in changing the cattle to a dairy breed. "Some districts appeared suitable for dairying—and dairying would pay infinitely better than their present system." "In many districts there was a dearth of milk during the winter and the children suffered therefrom."

Instead of the 4 lb. of mutton per acre which at present the hill grazings produce, we could have 50 lb. of beef or 50 gallons of milk; these latter standards are at present being attained on hill land. It is suggested that *in addition* 10 lb. of mutton per acre might be produced if hill grazings of Scotland were properly farmed instead of being ranched as they are at present.

THE STATUS OF THE PROTOZOA[*]

By Dr. JOHN R. BAKER

Department of Zoology, University Museum, Oxford

II

Death in Protozoa and Metazoa

It has been said by opponents of the cell-theory that since a single protozoon corresponds with a whole metazoon and not with a single cell, one might expect to find in Protozoa something corresponding to somatic death; and this is supposed to be represented by the degeneration of the macronucleus in Ciliophora and by comparable processes in certain Sporozoa[14]. It is necessary to consider the significance of this degeneration. The macronucleus of Ciliophora, as we have seen, must be assumed to contain the same gene-complex as the micronucleus, in polyploid form. But the degeneration of the macronucleus is particularly prone to occur precisely when the gene-complex of the micronucleus is changed, whether by conjugation or endomixis. The macronucleus is then replaced by a new one, containing the new gene-complex, presumably in highly polyploid form. Now it is supposed that the significance of conjugation and of endomixis is the origin of a new gene-complex. The necessary result of the degeneration is that the individual ciliate does not possess both the old and the new gene-complex, but *only the new*. If the old macronucleus were retained, it would swamp the effects of the new gene-complex, possessed by the reconstituted micronucleus. This, then, is surely the significance of the degeneration of the old macronucleus.

There is nothing that corresponds exactly to this process in Metazoa; but the degeneration of the chromatin in polar bodies is functionally similar, for if the genes contained in these bodies were retained in the egg, the old (diploid) gene-complex of the mother would co-exist, after fertilization, with the new (haploid) one brought in by the spermatozoon. One may, if one chooses, draw a rough comparison between the degeneration of the macronucleus and that of the chromatin of polar bodies; but there is neither homology nor functional correspondence with the death of a metazoon. In death there is decay of the whole of the protoplasm, not of the chromatin only; and in the ciliates the chromatin of the macronucleus does not appear even to be excreted. Roskin[15] has shown that the macronucleus of *Paramecium* may contain a considerable amount of ribose-nucleic acid, and it seems that at 'degeneration' there is a distribution of this substance throughout the organism. The most likely hypothesis is that 'degeneration' involves conversion of desoxyribose-nucleic acid into ribose-nucleic acid, with break-up of the chains of genes. There is evidence from Metazoa that desoxyribose- and ribose-nucleic acids are interconvertible, and it is likely that the ribose-nucleic acid dispersed through the body after degeneration may be built up into the 'chromatin' of the new macronucleus. This matter urgently requires investigation. There is nothing resembling death in the changes that are known to occur in the degeneration and reformation of the macronucleus. Death is a familiar process in the Protozoa, despite their potential immortality; and when it occurs, it shows no resemblance to degeneration of the macronucleus.

A Comparison between the Cleavage of Eggs and the Division of Protozoa

Those who deny that a protozoon can ever be regarded as a cell lay stress on a supposed difference between cleavage of an egg on one hand and the multiplication of a protozoon by division on the other. It is suggested that while the cleavage furrows are dividing the egg, the latter is being passively partitioned and the blastomeres are not increasing in volume, while in the Protozoa there is no mere partitioning by furrows, but a regular alternation between phases of division and phases of growth and differentiation. Actually it is doubtful whether any hard and fast distinction can be drawn between the two processes. When a protozoon is multiplying rapidly, the size becomes reduced. When division occurs within a cyst or firm cell-wall, for example, in *Chlamydomonas*, the size of the products of division is reduced just as in cleavage. To speak teleologically, the cleaving egg has generally no reason to grow, because sufficient food-substances have already been stored up inside it to last until a multicellular food-gathering apparatus has been formed. In some cases, however, the reserve food to be used by the embryo is external to the egg, and in such cases the blastomeres do grow, and may separate from one another in so doing and become irregular in form. This has been known for a long time. Growth of blastomeres was remarked by van Beneden[16] in the cleavage of *Tænia serrata*. The phenomenon is particularly clearly exhibited by some of the Turbellaria. For example, Hallez[17] found that if the volume of the egg of *Paravortex cardii* be taken as unity, that of the two-cell stage must be represented by 1·33 and that of the blastomeres of the four-cell stage by 5. In other words, each blastomere is now larger than the egg was: there has been even more growth than would have been characteristic of a protozoon. A similar state of affairs, though with less growth, is seen in the cleavage of the summer eggs of another rhabdocœl, *Bothromesostomum personatum*[18]. The most striking example of all is provided by the triclad, *Dendrocœlum lacteum*, for here the blastomeres are irregular in shape and lie quite

[*] Continued from p. 551.

separately from one another in a fluid derived from the yolk-syncytium; and they grow between one division and the next, so that the total volume is greater at the later stages of cleavage[19]. Since the blastomeres increase in size, are separate, and do not maintain a spherical shape, their resemblance to Protozoa is striking. There are, in fact, all gradations between *cleavage by partitioning* on one hand and an *alternation between phases of growth and of division* on the other; and all these gradations occur *both in Protozoa and in Metazoa.* No valid distinction between cells and not-cells can be drawn on the basis of differences of this sort.

Evolution of Metazoa from Protozoa

These considerations may be applied also to the evolution of Metazoa from simpler forms. There are those who consider that Metazoa originated by the failure of Protozoa to separate after division, while others insist that the many-celled condition arose by the appearance of partitions in a protozoon, and that until these partitions were formed, there was no such thing as a cell. Since there is no palæontological evidence and no one has ever seen a metazoon originate in evolution, this is not a matter on which certainty can be reached; but, as we have just seen, some Metazoa certainly originate in ontogeny in one way and some in the other, while others show an intermediate condition; and this shows that the two extremes are not alternatives, but the end-points of a series.

Dobell[20] has written, "The succession of individuals formed from one conjugation to the next is not comparable with a metazoan body any more than a swarm of bees is comparable with an elephant", and again, ". . . it is clear that a protist is no more homologous with one cell in a metazoon than it is homologous with one organ (for example, the brain or liver) of the latter". One must agree that a single elephant does not correspond with a swarm of bees: only a herd of elephants would be at all comparable. But the argument suggests that it is unthinkable that individuals should associate together to form an organism exhibiting a new grade of individuality. It is clear that bees could not do so, because their firm, chitinous external surface does not lend itself to the adhesion of one individual to another, and their organisation is such that they would be seriously incommoded in their activities by such adhesion; this kind of association is only to be expected in more plastic forms and in groups that possess the faculty of asexual reproduction. In such groups the association of individuals of one grade to form an individual of a higher does, of course, occur. Integration of this kind probably reaches its climax in *Pennatula.* No one who is familiar with the anatomy of this animal can doubt that each constituent polyp is comparable to a single *Haimea* or *Hartea* (or, to take a more familiar but less closely related form, *Hydra*). Yet the polyps of *Pennatula* are differentiated in structure in relation to their separate functions, their activities are integrated together, and the whole compound organism has even taken on a marked bilateral symmetry.

Now it would clearly be wrong to compare a single *Haimea* with a whole pinna of *Pennatula,* which consists of many polyps. This would be like comparing a single protist with the brain or liver of a metazoon. But there is no more absurdity in comparing a unicellular protist with a single cell of a metazoon than in comparing a single *Haimea* with a single polyp of *Pennatula.* Error could only arise if one were to choose a non-cellular protist, such as a radiolarian or ciliate, when making the comparison.

There has been some tendency for two separate questions to be confused. One may ask: 'Did Metazoa originate by the adherence of Protozoa after division?' To this no certain answer can be given, because no observations bearing directly on the point have ever been made. One may also ask: 'Is it logically conceivable that Metazoa originated by the adherence of Protozoa after division?' There can be only one valid answer to the second question, and that answer is 'Yes'. The suggestions to the contrary that may be found in the literature are not backed by evidence.

It may be remarked that while such forms as *Volvox* raise a storm of controversy among zoologists, they are not regarded as unusual by botanists, who are familiar with such colonial forms in groups other than the phytomonads. Botanists regard them as composed of cells, which are comparable on one hand with the individuals of what they call unicellular species, and on the other with the cells of higher but related forms, in which there is somatic differentiation (heterotrichous forms and other algal metaphytes).

If we seek the reason why zoologists are more divided in this controversy than botanists, we shall surely find it in a fundamental difference between plants and animals. In the lower plants *each group* tends to present both unicellular and metaphytic representatives, and botanists are repeatedly confronted with the intermediate forms. Metaphytes, in fact, have obviously originated independently many times, so that no one would propose the word 'Metaphyta' in any classification that was supposed to be based on evolutionary principles. With animals it is far different. Zoologists have not got intermediates again and again before their eyes. In the great group of Rhizopods, for example, there is no example of a multicellular form (the word 'cell' being here used as defined on p. 549). It would not appear that anyone has discussed the reason for this striking difference between plants and animals. The following suggestion may be made. The unicellular plant absorbs nutriment from all sides equally, and when, in the course of ontogeny or phylogeny, it becomes a metaphyte, there is no fundamental change in this respect: a cell divides without separation and the two products continue to absorb nutriment over most of their surfaces. The passage from the unicellular form to the metaphyte is therefore easy. In the case of animals, however, there is an important change when a unicellular form becomes a metazoon: a *new method* of feeding must be adopted. We see this particularly clearly in the ontogeny of *Dendrocœlum.* The blastomeres feed at first saprozoically, but at last a profound change occurs: a set of digestive organs originates, and a new method of nutrition begins. Most animals overcome this difficulty in ontogeny by placing enough reserve foodstuffs within the single-celled stage to make feeding unnecessary. It is easy to see what evolutionary difficulties must be presented when a *new system* of nutrition must be acquired before advance can occur. The difficulties would be greatest when a protozoon had a localized mouth. If the products of division of such an animal were to adhere together and each were to acquire its own mouth, no advance would be made towards the evolution of a metazoan alimentary canal. This suggests that the Metazoa may have arisen from primitive Protozoa, unprovided with localized organs of assimilation. These considerations seem to make it clear why intermediates between unicellular animals and Metazoa are rare, while intermediates between unicellular plants and metaphytes are common. (The colonial phytomonads are, of course, only regarded as animals by zoologists on account of their motility: their nutrition, it need scarcely be said, is holophytic or saprophytic.)

I acknowledge the help given by many friends in the course of conversation. In particular, I must thank Prof. A. C. Hardy, Dr. S. M. Manton and Dr. C. F. A. Pantin for valuable advice (though they must not be regarded as responsible for any opinion here expressed).

Summary

(1) A cell is defined as a mass of protoplasm, largely or completely bounded by a membrane, and containing within it a single nucleus formed by the telophase transformation of a haploid or diploid set of anaphase chromosomes.

(2) It is argued that many algæ and Protozoa are properly regarded as unicellular organisms.

(3) Certain Protozoa, notably the Radiolaria and Ciliophora, are not cells in the sense of the definition given above.

(4) It is argued that there is no fundamental difference between the cleavage of an egg and the multiplication of a unicellular protozoan by division.

(5) It is not unlikely that Metazoa may have arisen by the failure of unicellular Protozoa to separate after division.

THE BORDERLINE OF PSYCHOLOGY, PHYSICS AND MUSIC

At a meeting of the Acoustics Group of the Physical Society, held in the Science Museum, South Kensington, on February 12, three speakers contributed to a symposium on "The Borderline of Psychology, Physics and Music". The chairman was Mr. H. L. Kirke, head of the Research Department of the B.B.C. and chairman of the Acoustics Group.

Prof. Balth. van der Pol was the first speaker and he dealt with three problems: (*a*) the mathematical theory of consonance; (*b*) intonation from a purely musical point of view; and (*c*) absolute pitch.

In his discussion of the mathematical theory of consonance, Prof. van der Pol directed attention to the work of Leonhard Euler, who, in 1739, gave in his "Tentamen novæ theoriæ musicæ" a rigorous numerical measure for the "gradus suavitatis" or euphonic value of consonances and dissonances. This measure was the ratio of the least common multiple to the greatest common divisor of the frequencies of the component notes. Prof. van der Pol showed a table of the euphonic values of twenty-four 2-note, six 3-note and two 4-note combinations. It was clear that these euphonic values corresponded with the purely musical impressions of the relative consonances of the intervals and chords in question. The euphonic values of several familiar intervals are: unison, 1; octave, 2; twelfth and fifteenth, 3; fifth, 4; fourth, 5; tenth and eleventh, 6; greater sixth, 7; lesser and greater major second and lesser sixth, 8; lesser and greater seventh, 9; lesser major second and augmented seventh, 10.

Both Euler and Huygens suggested the introduction into music of the prime number 7, as all musical intervals used before could be represented by $2^l 3^m 5^n$, which led Leibnitz to state that musicians could count up to five only. Both suggested the dominant seventh chord: $g\ b\ d'\ f' = 4, 5, 6, 7$. The seventh of this chord, however, is too flat for musical purposes, as Prof. van der Pol demonstrated with an oscillator, with which he sounded the notes both separately and together. He showed that the chord 36, 45, 54, 64, the diatonic dominant seventh, is musically satisfying. The euphonic values of these two chords are 15 and 17, and it is clear that musicians would prefer the more dissonant of the two for æsthetic reasons.

On the matter of intonation from a purely musical point of view, Prof. van der Pol put forward the idea that the pitch of a note played is legitimately variable to a certain extent at the performer's discretion, just as the executant has some freedom in the matter of rhythmic interpretation. The intonation of *E* in the chord of *C* major may depend on its function as the third of the chord. In brilliant music, a sharp (Pythagorean) third will accentuate the typical and unmistakable quality of a major chord. Probably Beethoven was aware of this, though without knowledge of the underlying mathematical theory, when he indicated in the last movement of his Fifth Symphony, that the second note of the first bar should be an open *E* string. Similarly, in the main theme of Wagner's Meistersinger overture, also in *C* major, a sharp third should be played. The pitch of a note and its effect will, in fact, depend on the musical context.

A low third (the diatonic 5 : 4) will be appropriate in soft and floating music such as a lullaby. The leading note of the dominant seventh, thrusting towards the tonic, is not seldom sung too high, and often, indeed, the composer anticipates the tonic in his closing harmony. A Neapolitan sixth (*D*♭ in the chord *F*, *A*♭, *D*♭, in *C* major or minor) can, with advantage, be sounded low, because it leads down to the tonic.

Prof. van der Pol concluded with an account of experiments on the measurement of changes in absolute pitch, carried out on himself in 1939, with an oscillator by means of which a note of any desired pitch could be produced. During a fortnight, eighteen independent measurements of an *A* were made, as most closely conforming to his absolute pitch for that note. The estimates had a mean value of 435·2 c./s., with a mean deviation of 3·3 c./s. The greatest 'error' was 6·2 c./s., or a quarter tone. He explained that absolute pitch sometimes tends to vary in the course of years. The absolute pitch of a physicist friend of his had fallen 1·5 tones when he was about eighty years of age. Prof. Klein of Utrecht had communicated to him that the absolute pitch of the Dutch composer Wagenaar had remained unchanged up to his death at the age of seventy-nine.

The second contribution to the symposium was made by Dr. R. W. Pickford, who described three experiments on the relation of the impression of dissonance to the context of a chord. All the experiments were done by rating the critical chords on a 7-point scale running from −3 (very dissonant) to +3 (very consonant). Liking and disliking were kept apart, and in the third experiment these qualities were also rated in the same way. In the first experiment, forty women and eight men took part, and twelve chords were rated, each in six different settings and by itself. In the second, forty-three women and seven men rated fourteen chords in all of which the actual notes were identical. They were in settings mostly taken from familiar pieces of music. In the third, forty women and ten men rated fourteen chords in all of which the notes were identical, and which were in settings specially constructed for the experiment. The piano was the instrument used throughout. In the first experiment 'clang' effects were exploited, and in the other two interest was concentrated upon the musical preparation and resolution of dissonances.

It was found that familiar dissonances were given all kinds of ratings from very consonant to very dissonant, but most often they were classed as moderately dissonant, a seventh being classed on the average as less dissonant than a ninth, so that the average results were appropriate to musical expectation. There was a strong tendency for the consonance-dissonance level of chords to vary (*a*) with the context and (*b*) with the individual subjects' peculiarities of musical attitude and experience. Nevertheless, the chords had a strong tendency to retain their relative dissonance-levels in spite of these variations. There was a moderate tendency for liking to go with the impression of consonance, and disliking with that of dissonance. Smooth musical handling of dissonances tended to lead to the impression of consonance and also to liking, but departure from smooth handling led to various other combinations of liking, disliking, consonance and dissonance. The subjects were always astonished when told that they had rated the same note-combinations in different settings.

Helmholtz's theory of fusion appeared to provide the most satisfactory explanation of consonance and dissonance, apart from the effects of musical setting and individual attitudes of listeners. A Gestalt or 'form' theory of the effect upon the dissonance-consonance level of individual chords owing to their integral membership of whole passages or contexts should be added, together with a theory of personal schemata due to differences in musical ability and experience of individual listeners. Further experiments should be carried out on the relative effects of various musical techniques in handling dissonances and of 'clang' effects upon dissonance-consonance levels, and to compare these effects for pure tones and notes of complex timbre.

The third contribution to the symposium was made by Mr. J. Steuart Wilson. He pointed out that there are unfortunate tendencies at present to exploit the performer's capacity to vary the intonation of the intervals he sang or played. This is particularly noticeable in 'jazz' and 'swing', in which it has become an objectionable form of virtuosity. Even among serious musicians, some teachers trained their pupils to vary the intonation in playing classical music to produce special effects. Sometimes this had unfortunate results, because of the variety of thirds, for example, which might be included in a major common chord played by an orchestra. In addition, the liberties taken in 'jazz' and 'swing' had taught the public to like some effects which classical musicians eschewed, with the result that they thought that serious music was intolerably dull when it was really well played.

In the discussion the main speakers agreed that slight adaptations of pitch to suit the musical needs of a passage might be justified, provided that this did not lead to intolerably slovenly performance or to a form of senseless virtuosity. They also agreed that the impression of harshness of a dissonance might be expected to vary according to the way in which it was used. Mr. Steuart Wilson thought it most unfortunate that so many peoples' ideas of musical intervals came from listening to the pianoforte, which was often badly tuned either because nobody looked after it or because there was none to criticize the work of the tuner.

Dr. Dennis Fry pointed out that many people with absolute pitch are able to assign pitch to a sound which, for the majority, seems to be a noise without definite pitch. He asked whether people with absolute pitch might have two abilities, possibly separate in some cases: first, the permanent memory for pitch enabling them to compare pitches without reference to an external standard; and second, the ability to assign pitch to a frequency complex containing strong inharmonic components. In reply, Prof. van der Pol said that it is easier for most persons who have absolute pitch to assign pitches to notes which have many overtones than to pure single tones.

Dr. Fry asked whether the pitch of a given tone of fairly low frequency, say Middle *C*, 261 c./s., is recognized by a person with absolute pitch regardless of its intensity. If not, then at what intensity-level would it become Middle *C*? Also he thought it would be interesting to know what loudness-level of a pure tone of 261 c./s. gives rise to a pitch sensation exactly equal to that of a frequency complex containing a number of terms with a constant difference of 261 c./s. between them. Prof. van der Pol demonstrated the effect of varying the intensity of a given tone with his oscillator, but did not think data were available for answering the questions asked by Dr. Fry. It was suggested by Dr. Pickford that a valuable piece of research could be carried out in which adequate psychological experiments were performed with a large group of persons having various degrees of absolute pitch, in order to find out more about its variations among individuals, which might be very great. He also suggested that the euphonic value of an interval or chord, as defined by Euler, did not in itself determine the dissonance level of that chord. The only way to determine the euphonic value which would correspond to dissonance rather than to consonance would be to study the average of individual judgments and their variability. Most people would think that a euphonic value of 8 was dissonant; but the only way to determine this would be that of experimenting with large numbers of subjects.

R. W. Pickford

OBITUARIES

Prof. M. C. Potter

At the age of eighty-nine, Emeritus Professor the Rev. Michael Cressé Potter died on March 9 at New Milton, Hampshire, where he had lived since his retirement in 1925 from the chair of botany at Armstrong College (now King's College), Newcastle upon Tyne.

In 1877, Potter left the Perse School, Cambridge, and entered Peterhouse, where his father, who was rector of Corley, had preceded him and his uncle, the Rev. Canon Potter, had been a fellow. As, in addition, another uncle, Prof. Richard Potter, was a fellow of Queens', Potter rightly regarded himself as a well-established Cambridge man. He was ardent in support of his University on all public occasions. As an undergraduate he read natural science and graduated in 1881. He then read for the Mathematical Tripos, and in 1883 was classed senior optime. Shortly afterwards he was appointed to the post of assistant curator of the Herbarium under Prof. C. C. Babington, which became vacant through the tragic death by drowning of T. H. Corry. He assisted Dr. Walter Gardiner in re-establishing the University Botanical Museum, which had been founded by Prof. Henslow, and in commencing the preservation of botanical specimens in spirit.

Potter began his academic work when what was then known as the 'new' botany', introduced by McNab at Dublin and by Huxley and Dyer at South Kensington, was coming to the fore, and when practical laboratory investigation was being developed at Cambridge under the direction of the reader, S. H. Vines. He stressed the new ideas, and the economic importance of plants, in the long-vacation course of lectures he gave on systematic botany, and he arranged excursions and laboratory work. He delivered the first course of lectures given at Cambridge on the geographical distribution of plants. On two occasions he was awarded a Wort's travelling scholarship. In 1886 he went to Portugal and made observations on an alga which lived parasitically on the carapace of the water tortoise. In 1888–89 he studied the tropical flora in Ceylon.

In addition to these travels, Potter went to Heidelberg and attended Prof. Pfitzer's lectures there. He thus became familiar with the Continental system of classification, and used it in his lectures on systematic botany. In 1894 he translated and edited Dr. E. Warming's "Handbog i den Systematiske Botanik" in order to introduce this system to English-speaking botanists.

In 1889, after six years of rich experience, Potter took up a lectureship in botany and biology at Newcastle upon Tyne. In his first term there were only five students in natural history, none reading for a degree. In 1892 a chair was instituted, and Potter was its first occupant. Potter, who could be a determined man, eventually won his uphill fight to secure the recognition of botany as an independent subject at the intermediate and final pass and honours degree examinations. A measure of the success with which he built is the fact that on his retirement from the chair in 1925 he had four lecturers on his staff, and his department, which was fairly well equipped, could accommodate in reasonable comfort the 167 students of pure science, agriculture and medicine who were then attending courses in it.

The link between the Departments of Botany and Agriculture has always been strong. Potter did much in establishing it. The content of his course for agricultural students is indicated by that of his elementary "Text-book of Agricultural Botany", which was published in 1893. He also took evening classes for farmers and gardeners. He became interested in problems of plant pathology, and his researches culminated in the major discovery in 1899 that white-rot of turnips is caused by a bacterium, which he named *Pseudomonas destructans*. In his presidential address to the British Mycological Society in 1909 he gave the evidence that led to the recognition of bacterial diseases of plants, and placed his contribution in its historical setting. His interest in plant pathology and economic mycology was maintained throughout his life, and the subject received much attention in the curriculum he devised for students in science and in agriculture at Newcastle.

As a teacher and examiner, Potter laid great emphasis on experimental physiology. From 1895 (the date of publication of Darwin and Acton's book) onwards, students carried out experiments, even in the elementary agricultural and medical classes and examinations. Potter believed that, in those early days, the University of Durham's schools examination was unique in requiring a practical examination in botany in which each candidate was required to set up and explain a simple experiment and to determine a plant by means of a flora.

Some may regret that after 1910 his main research interest was transferred from plant pathology to electrophysiology, through his reading Dr. A. D. Waller's "Signs of Life". Physicists who knew about his work thought that such effects as he obtained were open to interpretations other than those he put on them. He held tenaciously to the idea that electrical effects accompany metabolism and are of primary importance in determining cellular activity. He may have been right. Who knows ?

During the First World War Potter showed his ardour by acting for a period as a volunteer in a Newcastle signalling unit raised for home defence, and later by taking Holy orders to relieve younger clergymen required by the Forces. Among his hobbies were campanology and dowsing.

M. THOMAS

Prof. E. Waymouth Reid, F.R.S.

THE death of Prof. E. Waymouth Reid in Edinburgh on March 10 has taken from us one of the pioneers of British physiology. Born in 1863 in Canterbury, the son of a surgeon, he was educated in Sutton Valence Grammar School, and went as a classical scholar to the University of Cambridge. After taking a first-class in anatomy and physiology in the Natural Sciences Tripos in 1883, Waymouth Reid worked in St. Bartholomew's Hospital, and graduated M.B. Thereafter he was for a time assistant electrician in St. Bartholomew's, but soon began his life's work as a physiologist, first as demonstrator and then as lecturer in St. Mary's Hospital Medical School. At the early age of twenty-seven he was appointed to the newly established chair of physiology in University College, Dundee, where he joined a body of highly gifted men who held teaching posts in the recently formed College affiliated to the University of St. Andrews. Waymouth Reid served the University for forty-six years, and after his retirement in 1935 the University of St. Andrews conferred upon him an honorary degree of LL.D.

Waymouth Reid showed his ability in the number and versatility of the published records of his research work. He contributed in 1898 noteworthy articles to Schäfer's "Text-book of Physiology" on diffusion, osmosis and filtration, and on secretion and absorption by the skin ; and papers in journals on a diversity of topics. He was made a fellow of the Royal Society in 1889, and later on received the honorary degree of Sc.D. from the University of Cambridge.

Waymouth Reid was especially interested in the physical mechanisms of living processes and kept in touch with modern developments. He was an early worker with X-rays, and investigated their effects on the animal organism, using his own body to its detriment. He was an expert photographer, and his laboratory was at one time richly equipped with apparatus for experimental purposes. At another time he occupied his spare time in the making of elaborate sweetmeats. He was always busy, and everything he did was done thoroughly.

He was largely instrumental in the development of what is now a very big and important concern, namely, the examination and reporting upon pathological material sent in to the College by medical practitioners in Angus, Fife and Perthshire. Much of the early work was done by Waymouth Reid himself, but it became so big that the University Court had to take it over and make special provision for it in the Department of Bacteriology.

Waymouth Reid was a good teacher and did not neglect that side of his Department's work. He was concise, humorous on occasions, and was liked and respected by his students. For some time he acted as dean of the Medical Faculty of the University, and took his share of administrative work. He was for a period one of the editors of the *Journal of Physiology*, a vice-president of the Section of Physiology at the annual meeting of the British Medical Association in 1898, and president of the Dundee Branch during 1903–4. He also acted as external examiner in physiology for the Royal College of Surgeons, the University of Cambridge, and the Royal College of Veterinary Surgeons.

On his retirement Waymouth Reid went to live in Edinburgh, but failing health lessened his activities, though he retained his mental acuity.

P. T. HERRING

WE regret to announce the following deaths:

Prof. F. O. Bower, F.R.S., professor of botany in the University of Glasgow for more than forty years, on April 11, aged ninety-two years.

Prof. Alexander Ogg, formerly professor of physics in the University of Cape Town, and a past-president of the Royal Society of South Africa, on February 23.

NEWS and VIEWS

Institution of Civil Engineers: James Alfred Ewing Medal

ON the joint recommendation of the presidents of the Royal Society and the Institution of Civil Engineers, the Council of the Institution of Civil Engineers has awarded the James Alfred Ewing Medal for 1947 to Sir John Cockcroft, for specially meritorious contributions to the science of engineering in the field of research. The medal is awarded annually and was founded in 1936 in memory of Sir Alfred Ewing. Sir John Cockcroft succeeded Sir Edward Appleton in May 1939 as Jacksonian professor of natural philosophy in the University of Cambridge. During the War he became director of the Air Defence Research and Experimental Establishment of the Ministry of Supply and a member of the Ministry's Advisory Council on Scientific Research and Technical Development. Later he became director of the Montreal Laboratory of the National Research Council of Canada, and of the Canadian Experimental Atomic Research Plant until early in 1946, when he was appointed director of the Atomic Energy Research and Development Establishment, Harwell, Didcot, formed under the Ministry of Supply to deal with all aspects of the use of atomic energy. He has published various papers on nuclear physics and also on technical subjects. In 1936 he delivered the thirty-seventh Kelvin Lecture before the Institution of Electrical Engineers, taking as his subject "The Transmutation of Matter by High-Energy Particles and Radiators". In 1946 he received the Hopkins Prize from the Cambridge Philosophical Society for researches carried out during the period 1933–39 on the artificial transmutation of elements. Sir John Cockcroft has been concerned with most of the major achievements of the Cavendish Laboratory during the past sixteen years, his advice having been sought on the design of much of its special equipment; he took a leading part in the construction of the cyclotron at Cambridge.

Hatfield Memorial Lecture of the Iron and Steel Institute: Prof. Robert E. Mehl

THE third Hatfield Memorial Lecture of the Iron and Steel Institute will be delivered in London on May 5, in connexion with the annual general meeting of this Institute, by Prof. Robert E. Mehl, of the Carnegie Institute of Pittsburgh. Prof. Mehl, who was born in Lancaster, Pa., on March 30, 1898, received his early training at Franklin and Marshall College, Lancaster, Pa., proceeding eventually to Princeton University, and, as a national research fellow, to Harvard University. He then became superintendent of the Division of Physical Metallurgy at the Naval Research Laboratory, Washington, D.C. (1927–31), inaugurating this division. In 1932 he became director of the Metals Research Laboratory and professor of metallurgy at the Carnegie Institute of Technology, Pittsburgh, Pa., and in 1935 head of the Department of Metallurgical Engineering in the Institute. Prof. Mehl has published many papers on the constitution of alloys, crystal structure, radiography, the electron microscope, the properties of forging steels, general metallurgy, theory of age-hardening, heat-treatment of steel, etc. He translated Gustav Tammann's book on "The States of Aggregation" (1925) and published his own book on the "Metallurgy of Iron and Steel" (in Portuguese) in Sao Paulo in 1944. His "History of Physical Metallurgy" was issued this year by the American Institute of Mining and Metallurgical Engineers.

Royal Zoological Society of Scotland

THE President and Council of the Zoological Society of Scotland have been informed by the Secretary of State for Scotland that the King has been graciously pleased to grant to the Society the privilege of prefixing the title "Royal" to its name, so that the proper title of the Society is now the Royal Zoological Society of Scotland. The Society, which is of national status, was formed in 1909 and was incorporated by Royal Charter in 1913, when the Scottish National Zoological Park, which it owns and controls, was founded. The Park has had the honour of several Royal visits and has been the recipient of a number of Royal gifts of animals.

August Gärtner (1848–1934)

Nestor of German hygiene, August Anton Hieronymus Gärtner, whose name is familiar to every medical student in Gärtner's Bacillus (*Salmonella enteritidis*), was born on April 18, 1848, at Ochtrub, Westphalia. He served in the Franco-Prussian War of 1870–71, and in 1884 became assistant to Robert Koch at the Kaiserliche Gesundheitsamt, Berlin. Two years later he was appointed to the chair of hygiene at the University of Jena, which he held until his retirement in 1914. As a teacher he was immensely popular, his genial personality endearing him to students and colleagues alike. It was in 1888, during an outbreak of meat poisoning in Frankenhausen on the Kyffhäuser, that he succeeded in growing the bacillus ever since known by his name. To the literature of hygiene he contributed his classic "Die Hygiene des Trinkwassers (1897), "Die Hygiene des Wassers" (1915), and, in co-operation with Ferdinand Tiemann, "Handbuch der Untersuchung und Beurteilung des Wassers" (1889–95). His "Leitfaden der Hygiene" was first published in 1892; a tenth edition was issued in 1923, and a French translation in 1895. In the First World War Gärtner served as 'Kriegssanitätsinspekteur' of prisoner-of-war camps. Preserving excellent health into advanced age, he died at Jena on December 21, 1934, in his eighty-seventh year. His autobiography appeared in *Centralblatt für Bakteriologie*, 107, 1, ii (1928).

Royal Aeronautical Society: Awards

The following medals and awards have been made by the Council of the Royal Aeronautical Society: *Society's Gold Medal*: Sir Bennett Melvill Jones, for his outstanding work in aerodynamics; *Society's Silver Medal*: I. I. Sikorsky, for his work on the development of the helicopter; *Society's Bronze Medal*: Miss F. B. Bradfield, for her work on aeronautical research; *Simms Gold Medal*: Sir William T. Griffith, for his paper "The Problem of High Temperature Alloys for Gas Turbines"; *George Taylor (of Australia) Gold Medal*: Dr. J. W. Drinkwater and W. G. Glendinning, for their paper on "The Risk of Fire and Fire Prevention Methods"; *Edward Busk Memorial Prize*: Air Marshal the Hon. Sir Ralph Cochrane, for his paper on "The Development of Air Transport During the War"; *R.38 Memorial Prize*: W. M. Widgery, for his paper on "Pressurisation of Aircraft"; *Branch Prize*, awarded for the best paper on an aeronautical subject read before the branches of the Society: A. N. Clifton, for his paper on "Naval Aircraft" read before the Southampton Branch, and J. A. Kirk, for his paper on "Wind Tunnels" read before the Belfast Branch.

Courtaulds' Scientific and Educational Trust Fund

Messrs. Courtaulds, Ltd., have announced the formation of the Courtaulds' Scientific and Educational Trust Fund, which has been formed with the object of encouraging study and research in those branches of natural science likely to assist the textile, plastics or other allied industries. The Fund provides for the establishment and maintenance of scholarships, and the provision of laboratory apparatus and equipment for education and research institutions. The Company will pay to the trustees the sum of £105,000, less tax, over a period of seven years. The trustees are Sir Edward Appleton, Sir Charles Tennyson, and, representing Courtaulds, Ltd., Mr. J. C. Hanbury-Williams (chairman), Mr. R. A. Butler, M.P., and Mr. R. A. Kinnes. The Trust will be administered by a management committee of representatives from the Company, together with Prof. C. N. Hinshelwood (University of Oxford), Prof. D. M. Newitt (University of London), and Prof. J. B. Speakman (University of Leeds).

Atomic Energy Commission Fellowships

The U.S. National Research Council has announced a new programme of fellowships supported by funds provided by the Atomic Energy Commission as a part of the Commission's responsibility for future atomic energy research. These fellowships will be awarded in the many fields of science related to research in atomic energy and the products of atomic energy processes. Some of the fellowships are available to those who wish to continue in graduate training or research for the doctorate in an appropriate field of science; others will provide training in biophysics applied to the control of radiation hazards. Further fellowships will be awarded to candidates less than thirty-five years old who have already obtained a doctorate and who wish to secure advanced research training and experience in aspects of the physical, biological and medical sciences related to atomic energy. The programme provides for two groups of fellows in the pre-doctoral field. One group will work in the biological and basic medical sciences, including applied biophysics, relating to the measurement and control of radiation hazards and the effect of radiation upon health; another group will be selected for study and research in the general field of the physical sciences. Awards will be made for the academic year 1948–49. Further information can be obtained from the Fellowship Office, National Research Council, 2101 Constitution Avenue, Washington 25, D.C.

American Summer Scholarships for European Students

The Massachusetts Institute of Technology, in co-operation with the students at the Institute, is offering approximately eighty scholarships to European students for study there for the period June 14–September 17. A certain proportion of these scholarships have been reserved for students in Great Britain. Any science or engineering student, male or female, who has completed approximately four years of university study, or any person who has recently graduated in the fields of science or engineering, is eligible; applicants must be more than thirty-five. All expenses will be paid by the Institute, with the exception of the cost of the trans-Atlantic passage, which may cost approximately £70 for the round trip. The summer seminar offers advanced courses in civilian and sanitary engineering, mechanical engineering, metallurgy, aeronautical engineering, architecture and planning, building engineering and construction, chemistry, electrical engineering, physics and chemical engineering. Further information concerning the subjects of instruction can be obtained from the Chief Scientific Officer in the United States Embassy, 5 Grosvenor Square, London, W.1. The last date for submission of applications is April 30.

Discovery of a Living *Metasequoia* in China

UNDOUBTEDLY one of the most interesting recent additions to our knowledge of the Chinese flora is the discovery of a 'new' conifer thought to be congeneric with Mesozoic fossil forms originally ascribed to *Sequoia* but now placed in a separate genus *Metasequoia*, as *M. Heerii*, *M. japonica*, *M. disticha* and *M. chinensis*. The living species of *Metasequoia* was discovered in north-eastern Szechwan in 1945, but is now known to occur more abundantly in Hupeh province. It occupies, however, only a limited area, and there is a grave danger that felling of the trees may lead to its extinction. Thanks, however, to the enterprise of the Arnold Arboretum of Harvard University and the co-operation of Chinese botanists, a special expedition last year obtained an ample supply of seed, and seedlings are now being raised in Britain as well as in the United States. The tree grows to a height of at least 115 ft., with a trunk diameter of at least 7½ ft., and is deciduous. In general appearance it is not unlike a *Glyptostrobus*. An account by Prof. E. D. Merrill of the discovery and introduction of this new *Metasequoia* has recently been published in *Arnoldia* (8, 1; March 1948).

British Fauna

THE Linnean Society of London is to be congratulated upon initiating a very useful piece of work in its "Synopses of the British Fauna", of which the first number was published in January 1944 and the most recent, No. 7, in 1947. The need for such synopses, particularly in the groups which do not attract the ordinary collector, like, say, Lepidoptera and Coleoptera, has long been felt by zoologists, naturalists and ecologists. The numbers so far published in order of appearance are: (1) Opiliones; (2) Caprellidea; (3) Gammaridæ; (4) Freshwater Bivalves; (5) Freshwater Bivalves (Unionacea); (6) Lumbricidæ; and (7) Talitridæ. The synopses are well printed, illustrated and provided with keys which in the two groups that have been used by the reviewer on several occasions are not difficult to use and do work. The price is reasonable, 2*s*. 6*d*., save for the largest, which is 5*s*. Individual numbers will naturally appeal to workers in their particular fields; but no institution that is likely to be concerned, however remotely, with faunistic work can afford to be without the complete set. It is to be hoped that the paper restriction will not slow down the rate of publication, or lead to the printing of insufficient copies of these synopses.

Research at the University of Birmingham

THE eighteenth annual report of the Joint Standing Committee for Research of the University of Birmingham, which covers the sessions 1938–39 to 1946–47, is a reference document of exceptional interest. The first section, covering the years from 1938–39 to 1945–46, gives a summary of the research carried out in the various departments of the Faculties of Science, Arts, Medicine and Commerce and also by the University Library, the Board of Research for Mental Disease, the Cancer Research Laboratory, and the Radiotherapy Department, Birmingham United Hospital. The summaries or notes on these researches are supported by full lists of publications under the Departments concerned. The second section of the report, covering the session 1946–47, in addition to a like list of publications embodying results of research completed in 1946–47, lists the personnel of the Committee, the research funds available for the session 1946–47, the conditions and procedure relating to applications for grants, th subjects of research towards which grants-in-aid have been made by the Committee and also other subjects of research during the session.

Atmosphere of Mars

THE December issue of *Sky and Telescope* contains a short note on the atmosphere of Mars which describes the work of Dr. G. P. Kuiper of the Yerkes and McDonald Observatories, on this subject. Using an infra-red spectrometer employing a Cashman lead-sulphide cell a thousand times more sensitive than any previous instruments of this type Dr. Kuiper has examined the spectra of celestia objects at wave-lengths of 1–2·5 microns, and has found that the atmosphere of Mars contains at least as much carbon dioxide as does the earth's atmosphere. Methane and ammonia appear to be absent. Dr. Kuiper believes that the Martian polar caps are probably ordinary snow and clouds of water vapour, and he was hoping to test this on February 17 when Mars was at opposition and near aphelion. If the polar cap visible at that time is sufficiently large for his test, it will be possible to measure the amount of water vapour on the planet with the new instrument.

Catalogue of Medical Films

THE Catalogue of Medical Films compiled by the Royal Society of Medicine and the Scientific Film Association, which are referred to in the catalogue as RSM and SFA respectively (ASLIB, 52 Bloomsbury Street, W.C.1, 1948. 7*s*. 6*d*. and 6*s*. to members of ASLIB and SFA), is a very useful small volume. It is the outcome of collaboration, suggested by the Royal Society of Medicine when it was considering the formation of a library of medical films. By March, 1946, more than 1,200 titles of films had been collected from lists held by commercial firms, medical schools and societies, university departments and private individuals. All the material thus collected has been entrusted to the care of the Scientific Film Association, to which all inquiries about it should be addressed (34 Soho Square, London, W.1). Eight hundred of the films have been viewed, and Part 1 of the catalogue groups them by subjects and catalogue numbers. Part 2 gives details of the availability of two hundred of the films. It shows that they come from various sources in Britain, Europe and the United States, and range from elementary instructional films suitable for health education of the lay public to films of difficult surgical operations and similar subjects suitable only for medical and scientific audiences. All the films listed in Part 2 are available, and more than one copy of each exists. Many other films not listed in Part 1 are also now available, and details of these can be obtained from the medical cataloguer of the Scientific Film Association.

Origins of Central American Culture

IN "Some Implications of the Ceramic Complex of La Venta" (*Smithsonian Misc. Coll.*, 107, No. 8), Dr. Philip Drucker presents an interim report on this important site in southern Mexico. The name has recently been applied to an early culture found at this and neighbouring sites, but he prefers the older term 'Olmec', which was abandoned owing to its association with a tribe inhabiting the area in historic times, because La Venta does not provide the most complete succession. The La Venta ceramics correspond, in fact, to the middle period only of the succession at the neighbouring site of Tres Zapotes. He gives an outline of the distribution of the culture, the centre of which is on the Gulf Coast of the Isthmus of Tehuantepec, showing how closely it is restricted in at least two directions by geographical obstacles. There is reason for believing that its markedly individual and well-known characteristics, which are seen in the sculpture rather than in the pottery, are due to development in place and not to outside stimuli. This conclusion is very important, since it cuts at the root of the idea, recently repeated in Morley's new book on the Maya, that that talented people was the fount of all Central American civilization.

Indian Society for Quality Control

An Indian Society for Quality Control, "to promote the advancement and diffusion of knowledge of the science of Quality Control and of its application to industrial processes", has been formed at Calcutta. A committee consisting of engineers, industrialists and statisticians has been set up to conduct the affairs of the Society. Mr. B. K. Rohatgi (director, India Fans, Ltd., and president of the Engineers Association of India) is president, and Prof. P. C. Mahalanobis is among the members of committee. Mr. R. D. Vidyarthi (102-A, Netaji Subhas Road, Calcutta) and Mr. N. T. Mathew (Indian Statistical Institute, Presidency College, Calcutta) are secretaries.

National Research Council of Canada: Publications

The second edition (1947) of Publications of the National Research Council of Canada (Ottawa) lists by authors and subjects all papers issued by it up to the end of 1946, these lists merely citing, however, the serial numbers of the publications in the "N.R.C." series. The major part of the document consists of a serial list of these publications, giving the full title, bibliographical reference if published elsewhere and the price of the reprint or paper in the N.R.C. series, up to number 1412. The *Canadian Journal of Research* has its own volume and number series, and for this reason is not included in the "N.R.C." series, although reprints of certain papers from it have been included.

Announcements

Prof. R. C. Punnett, formerly Arthur Balfour professor of genetics in the University of Cambridge, and Prof. A. H. Sturtevant, professor of genetics in the California Institute of Technology, Pasadena, California, have been elected honorary members of the Genetical Society of Great Britain, in recognition of their outstanding contributions to the science of genetics.

Dr. G. S. Hartley has been appointed research manager of Messrs. Pest Control, Ltd., Harston, to take charge of the Chemical Research Department. The company's research programme has for some time been devoted to the development of helicopter spraying, the formulation of aero spray chemicals and the development of selective insecticides to supplement biological control by chemical control on agricultural and horticultural crops in Great Britain, Europe and Africa.

Mr. R. H. Myers, head of the Steelmaking Division of the British Iron and Steel Research Association, has retired on account of ill-health. He is succeeded by Dr. A. H. Leckie, formerly deputy head of the Division.

The Challenger Society is prepared to consider applications for small grants in aid of research in marine biology or oceanography at a recognized laboratory during the year June 1948–June 1949. Applications, accompanied by details of the proposed research, should reach the Honorary Secretary, Mr. Dilwyn John, British Museum (Natural History), London, S.W.7, before the end of May.

Applications are invited for the John Gray Jubilee Scholarship of the Society of Chemical Industry, value £150, tenable for one year at any approved university or technical college. Candidates, who may be of either sex, should be graduates in chemistry whose intention is to enter industry, but those awaiting the result of their final degree examination may apply. Preference will be given to the son of a member of the Society of ten or more years standing. Applications must be made before July 10 to the General Secretary, Society of Chemical Industry, 56 Victoria Street, London, S.W.1.

A Busk studentship in aeronautics will be awarded during June. The studentship is of the value of about £165, tenable for one year from October 1; but a student may be reappointed on the same terms for a second year. It is open to any man or woman being a British subject and of British descent who has not attained the age of twenty-five years on October 1. Forms of application for the studentship, to be returned by June 1, can be obtained from the Professor of Aeronautical Engineering, Engineering Laboratory, Cambridge.

The first post-war exhibition of German books, periodicals and newspapers from all the occupied zones will be opened by Lord Pakenham on April 19, at 4 p.m., at the Academy Hall, Oxford Street, London, and will remain open for a week. The exhibition is being organised by European Periodicals Publicity and Advertising Co., Ltd., 2, 3 and 5 Studio Place, Kinnerton Street, London, S.W.1, with the view of stimulating the flow of scientific and cultural works from Germany to the rest of the world.

A short course for teachers of chemistry in technical colleges will be held at the Sir John Cass Technical Institute, London, E.C.3, during July 5–16. The main substance of the course will be the theory and practice of micro- and semimicro-inorganic analysis; spectroscopic analysis; small-scale organic preparative methods; electrochemical methods of analysis. There will also be lectures and discussions on teaching methods and recent developments. Visits to works will be arranged. Forms of application may be obtained from any local education authority for further education, or from the Ministry of Education (Short Courses), 14–22 Lennox Gardens, London, S.W.1. The closing date for application is May 15.

We have received from Messrs. Plant Protection, Ltd., Nobel House, London, S.W.1, a well-produced booklet on their 'Agrocide' range of insecticides. These are based on the synthetic compound 'Gammexane' discovered by Imperial Chemical Industries in 1942. In order that 'Gammexane' may be used in the most economical and efficient manner, Plant Protection have formulated its mixture with powders, solvents, etc. The results described are extremely encouraging and include the control of diverse insect types attacking a wide range of crops in many parts of the world.

Velocity of Meteors Measured by Diffraction of Radio Waves from Trails during Formation

IT is now well established that when a meteor enters the earth's atmosphere it creates a trail of electrons at a height of approximately 100 km.[1-4]. During the 1946 Giacobinid shower, Hey, Parsons and Stewart[5] measured the velocity of densely ionizing meteors by observing the radio wave scattered from the ionization at the head of the approaching meteor. We have recently succeeded in detecting the diffraction pattern of radio waves scattered from the electron trail as a meteor passes at right angles through the aerial beam. These observations lead directly to a measurement of the velocity of the meteor.

The basic transmitting and receiving equipment operating on a wave-length of 4·2 metres has already been described[2,3]. The additional apparatus consisted of a single-stroke time-base of duration 0·2 sec. on a separate cathode ray tube. The time base was automatically triggered by the radio echo from the meteor, and a photograph obtained of the successive pulse amplitudes occurring in the first 0·2 sec. of the echo. An example is shown in **Fig. 1**. The received power varies in an oscillatory manner, and the time intervals between maxima and minima are measurable from the photograph.

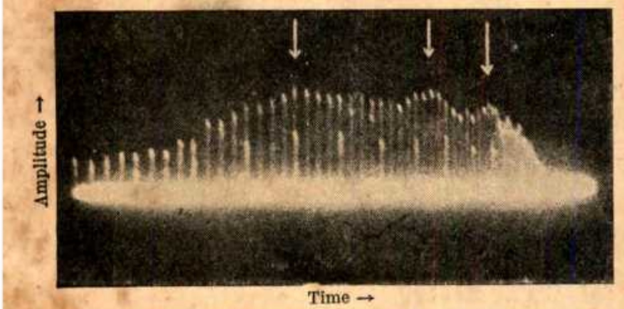

Fig. 1. QUADRANTID METEOR. JANUARY 4, 1948, 05h. 01m. ZONE MAXIMA MARKED BY ARROWS. RANGE 440 KM. MEASURED VELOCITY = 34·7 ± 2·2 KM./SEC. INTERVAL BETWEEN PULSES = 1·6 MILLISEC. EXPONENTIAL TIME BASE

It can be shown theoretically that the variation in the received power, as a meteor trail crosses the region about the perpendicular from the station, should be given by Fresnel's integrals, corresponding to the optical case of diffraction of light at a straight edge. The relative amplitudes of successive zones will not necessarily be given by the Fresnel integrals, owing to the non-linearity of the ionization along the trail[6]; but it will be shown that the *zone-lengths* obtained experimentally from individual meteor photographs agree with the zone-lengths given by the Fresnel integrals.

Calculation of the Fresnel integrals for a spherical wave gives values of the radii of successive zones, and subtraction between pairs of these values gives the theoretical zone widths, shown in Table 1, where R is the range and λ the wave-length. A, C, E are successive maxima, and B, D, F successive minima; A being the first maximum.

TABLE 1

$AC = 0{\cdot}55\sqrt{R\lambda}$ $CE = 0{\cdot}36\sqrt{R\lambda}$

$BD = 0{\cdot}43\sqrt{R\lambda}$ $DF = 0{\cdot}33\sqrt{R\lambda}$

In Table 2 the theoretical ratios of various zone widths are given, together with the equivalent ratios of four experimentally measured meteors at different ranges typical of forty-four obtained during the Geminid and Quadrantid showers of December 11–13, 1947, and January 4, 1948. It is assumed that the velocity of an individual meteor remains constant during the traverse of the zones, so that the measured number of pulses in the zone intervals considered is proportional to the length of the zones. The third meteor tabulated did not show a measurable F minimum.

TABLE 2

Ratios of zone	Theoretical	Experimental ratios (Quadrantid meteors) 1 360 km.	2 110 km.	3 470 km.	4 400 km.
AC/DF	1·68	1·59	1·57	—	1·88
AC/CE	1·52	1·56	1·50	1·48	1·61
BD/DF	1·32	1·16	1·38	—	1·36
AC/BD	1·27	1·37	1·13	1·28	1·38
BD/CE	1·19	1·14	1·32	1·15	1·16
CE/DF	1·11	1·01	1·05	—	1·17

Within the limits of experimental error, the ratios of the zone spacings agree with the theoretical values, so that the observed diffraction of radio waves from meteor trails obeys optical laws, and justifies the use of Fresnel's integrals for the calculation of velocities.

The time, T, to traverse a zone is determined from the measured number of pulses, p, and the known pulse-rate. Therefore the geocentric velocity, U, is given by

$$U = k\sqrt{R\lambda}/2T,$$

where k is the numerical value given in Table 1, appropriate to the particular zone selected.

The method has so far been applied to the Geminid meteor shower of December 11–13, 1947, and to the Quadrantid shower of January 3–4, 1948. The results are given in Fig. 2. The individual results for the Geminids are given in Table 3, which shows that meteors measured at widely different ranges give rise to constant mean values of $k\sqrt{R}/p$ as predicted by the above theory for the case where the velocity U is constant within a group of meteors.

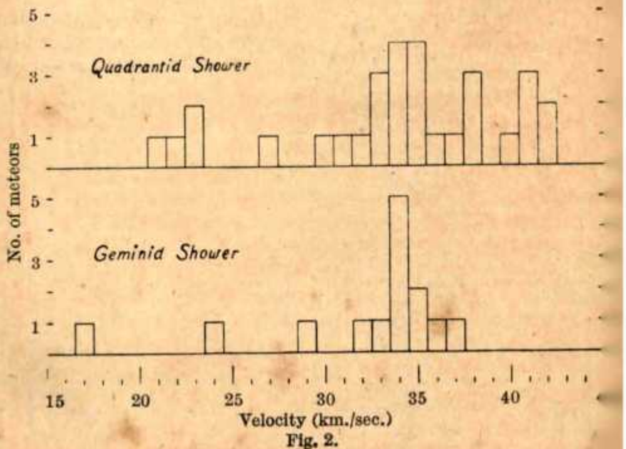

Fig. 2.

TABLE 3. GEMINID METEORS, DEC. 11–13, 1947

Range (km.)	$(k/p)_{\text{mean}} \times 10^{-2}$	$\frac{k}{p}\sqrt{R}$	Velocity (km./sec.)
460	7·85	1·68	33·7
470	7·90	1·71	34·3
170	13·60	1·77	35·6
370	8·95	1·72	34·6
370	8·84	1·69	34·1
420	8·32	1·71	34·2
400	8·74	1·75	35·1
440	7·90	1·66	33·2
220	11·32	1·68	33·8
490	8·30	1·83	36·9
400	8·07	1·61	32·4

The mean value for the geocentric velocity, U, of the Geminid meteors is 34·4 km./sec. (standard deviation 2·8 km./sec.), in excellent agreement with the velocity of 34·7 km./sec. obtained by Whipple[7] from photographic measurements of visible Geminid meteors.

The Quadrantid results indicate the existence of hree velocity groups. The only existing measurements with which these results can be compared appear to be the visual estimates collected by Fisher[8], which gave Quadrantid velocities of 32–46 km./sec., with a mean value of 38 km./sec. The Quadrantid results also contain a group of meteors with a very low mean velocity of 22·4 ± 1·8 km./sec. These were obtained using a non-directional aerial system at the beginning of the shower, and may not be associated with the Quadrantid radiant.

In the present experiments the range was measured visually on a cathode ray tube display and the maximum range error is estimated as ± 20 km. This introduces a mean error of 5 per cent in the range measurements, or 2·5 per cent (± 0·8 km./sec.) in velocity.

Amplitude fluctuations with a frequency of the order of 15 per second have also been found and are being investigated.

This work was carried out at the Jodrell Bank Experimental Station of the University of Manchester. We are indebted to Mr. N. Herlofson for suggesting the possibility that Fresnel zones could be measured[6], and to Dr. A. C. B. Lovell for constant interest and advice.

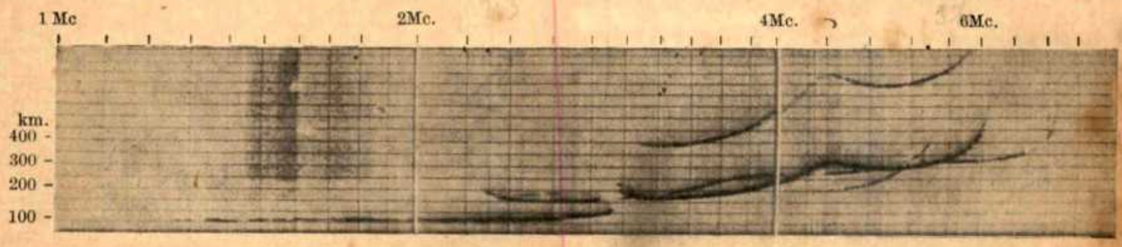
Triple Splitting of Ionospheric Rays

THE well-known theory of the ionosphere indicates the existence in polar regions of a third split in vertical incidence measurements of medium- and high-frequency radio wave reflexions from the ionosphere, its presence being due to the nearly vertical magnetic field of the earth. Its presence was first observed by Harang[1], and since then by others.

It was first seen in Canada in 1943 when the Churchill ionosphere station commenced operation. Since then the phenomenon has been observed frequently at other Canadian stations as well.

To date, observers have noted its presence only in the F_2 region; however, in Canada a complete trace is often seen extending from the E region through the F_1 region to the F_2 region.

The accompanying sample record was made with the National Research Council's automatic ionosphere recorder at The Pas, Manitoba (54·0° N., 101·0° W.). May 16, 1946, at 17.00 C.S.T. and illustrates some of the observed characteristics of the third split (z trace).



The following points may be noted:

(1) The z trace follows through from f^zE to f^zF_2.

(2) The down sweep on the left-hand side of the z trace indicates the presence of f^zE (2·3 Mc.), and on the original record there is evidence of retardation of the E region z trace to this point.

(3) $f^zF_2 = 5{\cdot}45$. $f^xFz - f^zF_2 = 1{\cdot}5$ Mc.
$f^oF_2 = 6{\cdot}10$. $f^xF_2 - F^oF_2 = 0{\cdot}85$ Mc.
$f^xF_2 = 6{\cdot}95$.

(4) The $F_1{}^z$ trace disappears at f^oE; this is a normal occurrence.

(5) Retardation at f^oF_1 is greater than at f^zF_1 and f^xF_1.

(6) The minimum virtual heights of the F region traces increase from z trace to o trace to x trace.

[1] Harang, L., *Terr. Mag. and Atmos. Elect.*, **41**, 143 (1936).

MR. GORDON NEWSTEAD, of Hobart, Tasmania, has observed a triple splitting of the rays reflected from the F region[1]. The occurrence of such triplets had already been observed in 1933, when they were described at a meeting of the Royal Society[2]. The signals were received on a polarimeter, so that the polarization of the triplets was known. These were always of the type of two ordinary rays and one extraordinary ray. The mechanism of the triplet was therefore known, and although no explanation was given in the paper, it had been discussed by Millington and myself.

If these triplets were due to the coupling between the ordinary and extraordinary rays, they would be expected to have one extraordinary and two ordinary characteristics—as, in fact, they have. That such coupling exists is without doubt, so that the explanation that it is the direct cause of the triplets observed is, I think, correct.

The frequency of the occurrence of these triplets is small. We received only five in five months. At Hobart, thirty-nine cases in fifty thousand records have been obtained. This is rather greater than we observed, but the explanation is, I think, quite correct.

The photograph shown is a very clear instance of this triple splitting, which has also been observed by Harang[3].

Blackett's Hypothesis of the Magnetic Field of Rotating Bodies

PROF. P. M. S. BLACKETT[1] has recently directed attention to the well-known, but forgotten, fact that the ratio of magnetic moment $\vec{P}$ and angular momentum $\vec{U}$ is roughly the same for the sun and for the earth and can be written in the form,

$$\vec{P} = -\beta \frac{G^{1/2}}{2c}\vec{U}. \quad . \quad . \quad . \quad (1)$$

Here G is the gravitational constant, c the velocity of light and β a dimensionless constant of the order of unity, which Blackett estimates to be 0·30 for the earth and 1·14 for the sun. Furthermore, from Babcock's measurements Blackett deduces the value $\beta = 1\cdot 16$ for the star 78 Virginis, but since the mass, radius and angular velocity are all deduced statistically in this last case and the sign is unknown, only little weight can be attached to it.

Next, Blackett urges that (1) may be generally true for all rotating, electrically neutral bodies and thus give a clue to a possible connexion between electromagnetic and gravitational phenomena. Quite apart from the secular variation, the fact that $\vec{P}$ and $\vec{U}$ are not parallel either for the earth or for the sun, and the fact that an eccentric dipole field gives a better description of the main field of the earth than does a centered dipole field, the relation (1) meets with the following difficulties.

On the analogy with the magnetic field of moving electric charges, the magnetic field of a rotating neutral mass may be interpreted from the point of view of non-atomic field theory, that is, as a field property depending on the relative motion of the body and the observer, as was done in the previous theory of H. A. Wilson on the magnetic field created by the translational motion of neutral bodies. However, in this interpretation one would expect the magnetic field to be different in a co-ordinate system which follows the body in its rotation, that is, in which the body is at rest, and in one relative to which the body rotates, because the gravitational field is different in these two co-ordinate systems. Since the main magnetic field of the earth as measured on the earth itself is experimentally found to be the same as that measured in even the fastest moving aeroplanes, the main magnetic field of the earth could scarcely be explained on such lines. (Nevertheless, this hypothesis might, of course, be true, that is, give an additional magnetic field not detectable on the earth itself. In that case we would expect the magnetic field acting on cosmic ray particles, which do not partake in the rotation of the earth, to be different from that measured on the earth.) However, on general principles it is rather unlikely that in classical field theory there should exist a connexion between electromagnetic and gravitational phenomena such as (1), because the sign of $\vec{P}$, but not of $\vec{U}$, depends on the definition of plus and minus electric charge, and thus north and south magnetic pole, which definitions are quite arbitrary. The signs can only be defined in an unambiguous way from an atomic theory involving a knowledge of the atomic constitution of matter.

Consequently, if the relation (1) should be generally true, as conjectured by Blackett, it must be interpreted from an atomic point of view as meaning that the body itself is magnetized, that is, that a magnetic dipole moment density is induced in the body when rotated relative to the inertial co-ordinate system of the fixed stars. However, in that case, first one would expect (1) to contain not only classical constants such as G and c, but also both atomic constants and constants characteristic for the material of the body[2]. Secondly, it is difficult to imagine another atomic mechanism to give a relation like (1) than the gyromagnetic—which, however, gives a uniform magnetization, and thus for a sphere $P \propto M\omega \propto \frac{U}{R^2}$. (This form of magnetization is just an example of one which occurs for rotational but not for translational motion.) Thirdly, also in this case of a rotating electrically neutral mass the body would be associated not only with a magnetic field, but also with an electric field, as pointed out by Blackett in the case of translational motion. For from the Lorentz transformation it follows that each volume element carrying a magnetic dipole moment $\vec{dP}$ will show in a co-ordinate system relative to which the element moves with velocity $\vec{v}$ an electric dipole moment given by $\frac{1}{c}\vec{v} \times \vec{dP}$ (for $\frac{v^2}{c^2} \sim 0$). For example, a symmetric rotating body will thus be surrounded by an electric quadrupole field, and no rotating body can be surrounded by a purely magnetic field. (The influence on the motion of cosmic ray particles of this electric field which must surround the earth ought to be investigated more closely.)

We note that it may be possible experimentally to test Blackett's hypothesis (1) by the experiments of Barnett on the gyromagnetic magnetization (or perhaps by the experiment of Einstein and de Haas on the inverse effect of rotation by magnetization)[3]. For example, for a cylinder with radius R and density d and making ν rotations per second we get from Blackett's hypothesis an average magnetization of $\bar{I}_{\rm Bl} = 7\cdot 9 \times 10^{-15}\ \nu\ dR^2$, whereas the gyromagnetic effect gives a uniform magnetization $I_{\rm gy} = 3\cdot 6 \times 10^{-7}\ \chi\nu$ (χ is the susceptibility of the body). Thus the two magnetizations are of the same magnitude if $\frac{dR^2}{\chi} = 5 \times 10^7$. Taking, for example, a paramagnetic material like aluminium for which $\chi = 1\cdot 7 \times 10^{-6}$ and $d = 2\cdot 7$, this is the case already for $R \sim 5$ cm. Before such experiments are performed with a positive result we think it is more probable that if (1) is not merely accidental, it may be due to a common origin of $\vec{P}$ and $\vec{U}$, since it is possible that their values are determined already by the creation process of the earth and the sun.

[1] Blackett, *Nature*, **159**, 658 (1947).

[2] Cf. also the theory of Pauli, *Ann. Phys.*, 18, 337 (1933), especially p. 372 where $G^{1/2}/c$ occurs in connexion with h.

[3] See, for example, Barnett, *Rev. Mod. Phys.*, 7, 129 (1935).

IN his paper on the magnetic field of rotating bodies, P. M. S. Blackett has shown[1] that the relation $(P/U)_1$ between magnetic moment P and angular moment U of a rotating body seems to be independent of its size and constitution (about $0{\cdot}95 \times 10^{-15}$ E.M.U.); he also tried to explain the physical significance of this constant. He based his considerations on the well-known equation for the Bohr magneton, which is written

$$\left(\frac{P}{U}\right)_2 = \frac{e}{2mc} = 0{\cdot}88 \times 10^7 \ [\text{cm.}^{1/2}\ \text{gm.}^{-1/2}]. \quad (1)$$

Blackett points out that the empirically determined relation

$$\frac{(P/U)_1}{(P/U)_2} = 1{\cdot}08 \times 10^{-22}$$

corresponds in order of magnitude with the well-known non-dimensional equation

$$G^{1/2}\frac{m}{e} = 4{\cdot}90 \times 10^{-22} \ [\text{E.S.U.}] \quad (2)$$

(G is gravitational constant). For this reason, the new relationship

$$\left(\frac{P}{U}\right)_1 = G^{1/2}\frac{m}{e}\left(\frac{P}{U}\right)_2 \quad (3)$$

was introduced. By putting (1) in (3) he was able to show that

$$\frac{P}{U} = \frac{G^{1/2}}{2c} \quad (4)$$

represents the magnetic moment of a rotating body as a function on one hand of the angular moment, and on the other of the gravitational constant and the velocity of light.

In its present form, however, equation 4 is, from the physical point of view, not complete. The term c in that equation, for example, should not be identified with the velocity of light. This value is taken from equation 1, where it is only used to transform the value of e, quoted in electrostatic units, into electromagnetic units. Therefore equation 1 should be written in a more general manner, independent of any system of units, as

$$\left(\frac{P}{U/2}\right)_2 = \frac{2P}{h/2\pi} = \mu\frac{e}{m} \quad (1a)$$

(where μ is permeability of a vacuum, h is Planck's constant; the number 2 originates from the definition of the angular momentum and belongs therefore to U). Only in this form is equation 1 correct with reference to any system of dimensions.

Equation 2 also does not contain all the necessary physical quantities to make it correct dimensionally. The equation should be completed and then read as

$$\frac{\varepsilon^{1/2}G^{1/2}m}{e} = 4{\cdot}90 \times 10^{-22} \quad (2a)$$

(where ε is the dielectric constant of the vacuum). It becomes obvious that the above equation is now a non-dimensional one if the reciprocal value of G, namely, $1/G = \gamma$, is introduced; the result is the symmetrical equation

$$\frac{\varepsilon^{1/2}}{\gamma^{1/2}}\frac{m}{e} = 4{\cdot}90 \times 10^{-22}. \quad (2b)$$

Blackett's equation 3 must then be written as

$$\left(\frac{P}{U}\right)_1 = \frac{m}{e}\sqrt{\frac{\varepsilon}{\gamma}}\left(\frac{P}{U}\right)_2. \quad (3a)$$

If (1a) is put in (3a), then finally equation 4 will be replaced by

$$\frac{P}{U/2} = \mu\sqrt{\frac{\varepsilon}{\gamma}}. \quad (4a)$$

This equation is numerically correct not only in the usual non-rational electrostatic system but also in the non-rational electromagnetic system of units, where the following relations are valid:

	E.S.U.	E.M.U.
$\varepsilon =$	1	$\frac{1}{9} \times 10^{-20}$
$\mu =$	$\frac{1}{9} \times 10^{-20}$	1
$\gamma =$	$1{\cdot}5 \times 10^7$	

The removal of the factor c from equation 4 has led now to equation 4a, which is correct in any system of units and dimensions and shows that the new relation ε/γ (of the dielectric constant to the gravitational constant) may be one of the decisive relations concerned in this matter.

It is furthermore easy to understand that the permeability μ must play an important part in (4a), as we are dealing here with fundamental *magnetic* questions; indeed, it would be surprising if this physical quantity were not involved when dealing with such a matter.

In any event, the fact that the general electric properties of matter are decisive for the formation of the steady magnetic field of rotating massive bodies is best shown by equations 4a and 1a in the form

$$P = \frac{U}{2}\mu\sqrt{\frac{\varepsilon}{\gamma}} = \frac{U}{2}\mu\frac{e}{m}. \quad (5)$$

Spontaneous Waves in Discharge Tubes and in the Solar Atmosphere

A THEORETICAL study has been made of the plane electromagnetic waves which can exist in a strongly ionized gas when a constant electric field $\mathbf{E}_0$ and a constant magnetic field $\mathbf{H}_0$ are both present. As the results of this work appear to be of general interest, a brief account of them is given here.

It is found that in general for waves of a given frequency the medium is octuply refracting and that, under certain conditions the absorption of the medium is negative, that is, the medium acts as an amplifier for one or more of the types of wave which can travel through it with the given frequency.

It is found similarly that in the medium there are eight possible types of wave with a given wave-length and three possible types with a given phase-velocity, and that under certain conditions one or more of these types can exist with the property that at any given place the *amplitude of the wave grows with the lapse of time* up to one of two possible limits.

The presence of a constant electric field is essential for the existence of growing waves. The addition of a constant magnetic field increases the possibility that spatially growing or secularly growing waves can exist in the medium and also increases the range of their frequencies.

These results of the theory can be applied to the ionized gas in a discharge tube or in the solar atmosphere.

In different parts of the tube the electron and ion densities and the electric field can vary in magnitude considerably. It is therefore possible for conditions to exist in which waves can grow from any random fluctuation of these magnitudes. The phase-velocities and the corresponding frequencies of these growing waves will depend on the form of this initial fluctuation as expressed by means of a Fourier integral. In this way electric noise can arise over a large range of frequencies. The addition of a magnetic field serves to increase these possibilities. The existence of boundaries in a discharge tube will under certain conditions favour the development of certain waves into steady types each with a definite wave-length and its associated frequency.

The abnormal solar noise which has been much studied in recent years can be explained in a similar way if we postulate that constant (or slowly varying) electric fields can arise in the solar atmosphere, and that large local transient changes in this atmosphere can occur from time to time. There is little doubt that both these conditions do occur on the sun.

A similar explanation can be advanced for cosmic noise if we regard this noise as originating in the ionized atmospheres of stars, especially of those which are magnetic.

A detailed account of this work will be published elsewhere.

Method of Steepest Descents: Improved Formula for X-Ray Analysis

BOOTH[1] uses two formulæ as a starting point of the method of steepest descents, applied to X-ray crystal structure analysis:

$$R_1 = \Sigma \Big| \, |F_0| - |F_c| \, \Big| = \text{minimum}, \qquad (1)$$

$$R_2 = \Sigma \, (F_0^2 - F_c^2)^2 = \text{minimum}. \qquad (2)$$

According to the method of least squares, a formula of the form Σ (error)^2 = minimum is correct only when all the observations have the same weight and when the errors follow Gauss's law. As the intensities are $I \sim F_0^2$, formula (2) assumes equal weights of all the measured intensities. This might hold for initial steps of approximation; but for final steps the average errors are proportional to the intensities and the errors do not obey Gauss's law. However, when logarithms of intensities are plotted, the average errors in the logarithms are constant and Gauss's law is obeyed. It follows thus that, at the later stages,

$$R_3 = \Sigma \, (\log I_0 - \log I_c)^2 \qquad (3)$$

should be minimized rather than (1) or (2). Zero observed intensities can be avoided by substitution in (3) for I_0 the threshold observed intensities I_t, except when $I_c < I_t$; then the error should be put equal to zero. The formula (3) should be used only at a stage of approximation when all the signs of F_c remain constant.

The change ε_{rj} of the atomic co-ordinates x_{rj} in any one step can be regarded as a vector ε in the $3N$-dimensional space; its direction is given by the direction cosines grad $R/|$ grad $R|$ and its magnitude by $|\varepsilon| = s$. Writing $|$grad $R| = D$, we have

$$\varepsilon = \frac{s \text{ grad } R}{D}. \qquad (4)$$

Along the normal, R is a function of s only; we can thus write:

$$R(s) = R(0) + Ds + \frac{1}{2!} D_2 s^2 + \frac{1}{3!} D_3 s^3 + \ldots, \qquad (5)$$

where D, D_2, D_3, etc., are the derivatives of R along the normal at the point $s = 0$.

Neglecting higher power terms in s than the second,

$$dR/ds = D + D_2 s, \qquad (6)$$

so that for a minimum of R, the value of s is $s_m = - D/D_2$. By substituting this in (4)

$$\varepsilon_m = - (\text{grad } R)/D_2, \qquad (7)$$

which is equivalent to the first formula of Booth. Neglecting higher-power terms in s than the second, (5) can be written as

$$R(s) = R(m) - \frac{1}{2} D(s - s_m)^2/s_m. \qquad (8)$$

If we assume $R(m) = 0$, or negligible compared with $R(0)$, we have $s_m = - 2R/D$. Substituting this in (4),

$$\varepsilon = - 2R \text{ grad } R/(\text{grad } R)^2, \qquad (9)$$

which is the second formula of Booth, and which contains first partial derivatives only. When, however, $R(m)$ cannot be neglected, then (9) gives too large a shift. When x_{rj} are near their optimum values, ε calculated from (9) may be much larger than ε_m, and R may even increase; Booth then recommends the use of (7).

A method has been devised by which the laborious calculation of D_2, which contains many second partia derivatives of R, is obviated even near optimum values of x_{rj}, resulting in a great saving of time According to this method, ε is first calculated from (9) even when x_{rj} are near their optimum values and R increases. The shift calculated is thus $s_1 = - 2R/D$ The value of $R(s_1) = R(1)$ is calculated from (3) However, now we know two points $R(0)$, $R(1)$ and a tangent D at $s = 0$ of the curve $R(s)$. This allow us to calculate from the three conditions the value of D_2:

$$D_2 = 2(R(1) + R(0))/s_1^2,$$

and thus $s_m = s_2$ is given by

$$s_2 = - D/D_2 = R(0) \, s_1/(R(0) + R(1)). \qquad (10)$$

At this point

$$R(m) = s_2 R(1)/s_1. \quad (11)$$

Using now s_2 instead of s_1, we calculate $R(2)$ from (3) and compare it with $R(m)$ calculated from (11). If $R(2) = R(m)$, our assumption of higher derivatives being zero or negligible was justified. If the effect of higher derivatives is not negligible, the process can be repeated until minimum is reached.

If the observed F_0 are not on an absolute scale, they can be adjusted by multiplying them by a constant K, given by

$$\log K = -\frac{1}{N} \Sigma (\log F_0 - \log F_c). \quad (12)$$

This adjustment of the scale can be repeated after each approximation, as the changes of the co-ordinates may also affect the value of K.

We have successfully applied these methods to the three-dimensional refinement of parameters of a crystal of potassium caprate, a preliminary report of which was given by Vand, Lomer and Lang[2], and to the structure of lauric acid.

I wish to thank Messrs. A. Aitken, W. M. Morley and Miss B. Edkins for testing the method, and the directors of Lever Brothers and Unilever, Ltd., for permission to publish this note.

Surface Resistance of Metal Films at a Frequency of 24,000 Mc./s.

The reflexion, transmission and absorption coefficients (R, T, A) of a thin metal film can be expressed in terms of its surface resistance S, if the frequency is low enough for classical electromagnetic theory to apply. Then measurements of R, T, or A yield theoretical values of S which can be compared with the value (S_0) obtained from D.C. measurements on the film. Experiments of this type have been carried out[1-3] at infra-red wave-lengths (6–110 μ); but while a measure of agreement has been obtained, the anomalies suggest that dispersion occurs at these short wave-lengths. With the view of effecting a similar comparison between S and S_0 at centimetre wave-lengths, the theory has been investigated afresh[4] to include the effect of multiple reflexions occurring in the film and its support, and has been extended to find the resonance condition for a cylindrical cavity resonator operating in the H_{01} mode, when it is loaded with a film of metal carried by a low-loss support travelling on the plunger. The theoretical value of the surface resistance is then given by the expression

$$S = \frac{120\pi\lambda_1}{\lambda\left[1 + \cot\frac{2\pi l'_1}{\lambda_1}\left\{2\cot\frac{4\pi l_1}{\lambda_1} - \cot\frac{2\pi l'_1}{\lambda_1}\right\}\right]^{1/2}},$$

where λ is the wave-length in air, λ_1 that in the empty resonator, while l_1 and l'_1 are the resonant lengths of air space in front of the support in the presence and absence respectively of the film. In practice, λ is calculated from λ_1 and a resonator dimension, while l'_1 may either be measured directly, or calculated from the thickness and permittivity of the film support.

Extensive measurements have been made at a frequency of 24,000 Mc./s. to test this relation and certain other theoretical predictions. For this purpose films of chromium, gold, aluminium, silver, copper and nickel of uniform thickness have been prepared by evaporation *in vacuo* on silica disks, some of which have been optically flat. Silica was chosen as the material for the film support because of its extremely small loss, and its permittivity at this frequency has been evaluated as 3·8 ± 0·001. After measuring S, the value of S_0 has been determined in each case by evaporating thick silver contacts on to the film and measuring the resistance of a circular annulus by bridge and other methods. The film thicknesses investigated have lain in the range 5–300 A.; for most metals this covers a range of values for S_0 lying between infinity and a few ohms/cm.[2].

Throughout this range the qualitative agreement between S and S_0 has been excellent. Thus if $S_0 = \infty$, the A.C. measurement always yields a value of $l_1 = l'_1$, so that $S = \infty$. Again, a low value of S_0 always corresponds to a low value of S, that is, $l_1 \sim \lambda_1/2$. Films with intermediate values of S give values of l_1 lying between these extreme limits, and the phase shift due to the film may be large. However, the high absorption of such films lowers the effective Q of the resonator, and the broadening in the response renders the precise determination of l_1 difficult. Nevertheless, the quantitative agreement between S and S_0 over the entire range of values is good. It is found that S is always less than S_0, the ratio S_0/S generally lying between 1 and 2. A part of this small discrepancy can be attributed with certainty to the effect of the evaporated contacts on the film, since different contacts give slightly different values of S_0. Aggregation in the film or surface oxidation occurring on exposure of the film to air would also contribute to the higher value of S_0. Finally, the same agreement between S and S_0 has been found for films of metal contaminated with oxide, suggesting that the agreement is of a statistical nature.

Since any wave trapped in the resonator is partially reflected and transmitted by the film several times, the expression given for S represents a more stringent test of the theory than any of the expressions for R, T, A used in the infra-red, which depend on a single encounter between the wave and the film. The agreement obtained experimentally between S and S_0 must therefore be regarded as very satisfactory, indicating that the theory and underlying assumptions are valid and that no dispersion occurs in the metal at this frequency. The resonator method can thus be used to study other film properties connected with the electrical conductivity, for which purpose it has the advantage that no contacts to the film are required.

This work was partly carried out at the Clarendon Laboratory, Oxford; a fuller account will appear elsewhere.

A Large Field Compensator for Measurement of Birefringence

A FROZEN stress compensator using a *C R* 39 resin strip, such as is described by Messrs. P. E. Jellyman and A. J. Milne in *Nature* of March 27, p. 477, was constructed and used at the Naval Construction Research Establishment, Rosyth, in 1944. It was briefly described in a paper read to the Edinburgh and District Association of the Institution of Civil Engineers in November 1944.

The instrument could not be made to be as stable as a quartz wedge compensator, but fulfilled a useful purpose, while the delivery of a Soleil-Babinet compensator was awaited.

The Swimming of Dolphins

DOLPHINS in the Gulf of Panama have been seen moving through the sea at a speed of ten knots, their entire bodies showing no apparent swimming motion. This performance was confined, in my observations, to the area immediately forward of the stem (prow) of a sea-going tug and to an estimated depth of one metre or less. Elsewhere near the bow, vertical oscillations of dolphins' tails were readily timed with a stop watch.

When this 'motionless' swimming was first noticed, the animals were in the normal swimming position. In this position it was difficult to be sure that vertical motions of their tail surfaces were not occurring, since the direction of such motions would be nearly parallel with the line of sight of the observer. However, on several occasions dolphins were seen to turn on their sides during the 'motionless' swimming in such a position that their usual swimming motions would have been normal to the line of sight. No motion was visible in these animals, which were clearly seen just below the surface of the water. One animal remained on its side in this manner for 59 sec., which represented a distance, at 5·15 m./sec. (10 knots), of 304 metres. At this time dolphins swimming near by used 1·9 tail oscillations per second in keeping pace with the vessel.

These 'motionless' dolphins seemed to be riding the bow wave (that is, falling down the inclined surface). However, if dolphins are equal in weight to the weight of the water they displace, wave riding is not possible. No data have been found concerning their density. Kellogg[1] says, however, that dolphins usually sink when shot. Is it possible that they are dense enough to fall down the advancing slope of the bow wave, having achieved terminal velocity initially by swimming? A low over-all resistance to motion through the water would seem to be required. Gray[2] has indicated that the work done by dolphin muscle in producing a speed of 10 m./sec. is comparable to the work of other mammalian muscle tissue, if laminar flow is assumed around the dolphin. With turbulent flow, Gray found that the work done by dolphin muscle at 10 m./sec. would be about seven times the work of other mammalian muscle. If a laminar regime exists at a speed of 5 m./sec., perhaps the over-all resistance to the motion of a dolphin is low enough to allow an animal, of sufficient negative buoyancy, to fall down the inclined water surface of a bow wave or other waves.

It may be thought that the dolphins were gaining a forward thrust by placing their tails against the ship's stem. Dolphins have been seen with their tails in momentary contact with the hull, but in the above observations of 'motionless' swimming the animals were clearly forward of the vessel.

Shoulejkin[3] suggests that the speed of motion of the dolphin's tail may be very rapid. Dolphins seen 'motionless' in the bow wave may have been using rapid tail oscillations of very small amplitude, causing them to appear to be motionless. If such swimming motions were in fact occurring, it is curious that the use of this propulsive technique should be confined to the immediate vicinity of the bow, while other dolphins a few metres away always used a large amplitude vertical tail motion with a period of about half a second (at 10 knots).

I would like to know whether other observers have seen this 'motionless' swimming, and what explanations may have been given.

Control of Cattle Trypanosomiasis

MRS. ELSPETH HUXLEY suggested in a letter in *The Times* (Sept. 16, 1947) that possibly cattle trypanosomiasis might come to be controlled by immunological methods. If this were achieved, resettlement of tsetse-infested land could be accomplished without such undesirable features as the destruction of plant and animal life. On the assumption that man and tsetse flies are ecologically incompatible, resettlement must cause recession of the 'fly'. Domestic stock are, therefore, the key to the problem, since tribal customs in East Africa are such that a threat to the stock constitutes a threat to the community. Resettlement is only possible if stock can be enabled to survive in 'fly'-infested areas.

There is a certain amount of evidence that, with intensified research, means could be found to 'salt' cattle, so as to enable this to be accomplished.

Survival of game in tsetse-fly areas. Carmichael at Entebbe (unpublished data) found that the young of game animals, notably duiker and sitatungu, which abound in tsetse-fly areas, are as susceptible as domestic animals, to artificial infection with *T. congolense.* It follows that the immunity of some game animals at any rate is acquired and not hereditary.

Survival of cattle in tsetse-fly areas. Cattle in many parts survive in tsetse-fly areas, as reported from Kenya, Southern Rhodesia and the Gold Coast. Such cattle are usually deliberately exposed by the owners to tsetse-fly attack from birth onwards.

Immunity of cattle to T. congolense. Young calves usually recover from infection with *T. congolense*[1-3]. Taliaferro[4] has demonstrated solid immunity to *T. lewisi* in rats following recovery; the same has been demonstrated by Fiennes[5] in the case of cattle, but only to the infecting strain.

Laveran and Mesnil[6], in re-infection experiments with goats, could only demonstrate four strains of *T. congolense.*

Control by drug therapy. Trypanosomiasis of cattle can be successfully controlled by drug therapy. Observations on the cattle of a European farmer who has established a herd of nearly a thousand cattle in a tsetse-infested area appear to show that drug control over a period of years will lead to the development of stock which become somewhat resistant to, or tolerant of, the parasite.

Development of resistance in cattle by artificial means. In the case of twenty cattle, some infected with *T. congolense* and some with *T. vivax*, a fatal course has been converted to a benign one by means of subcurative dosage with phenanthridinium compounds. This work is not yet complete, but it can be said that all the cattle are healthy and some are surviving after carrying the trypanosome for more than fourteen months. One calf was born to an infected dam and was infected at birth. The calf has never been sick, and at six months old is thriving. It remains to be seen whether the parasite will eventually be eliminated, and if so what degree of immunity will be developed.

Control of trypanosomiasis in cattle. The evidence given is scanty, because the pathology and immunology of the trypanosomiases have been virtually neglected for the past thirty years. Nevertheless, it may suggest that an attack on these lines might bring the most rational solution to the tsetse-fly problem, by enabling breeding herds to be established in 'fly' areas and by resettlement with human populations and consequent elimination of 'fly' by natural ecological means.

What has been written is a simplification of the problem, inevitable from lack of space.

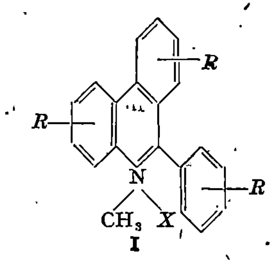
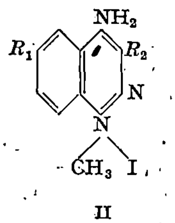
Cinnoline Derivatives as Chemotherapeutic Agents for *Trypanosoma congolense* Infections

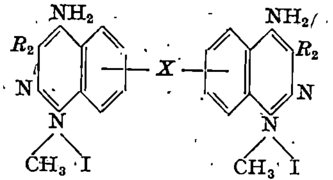
THE most important disease of cattle throughout tropical Africa is that due to infection with *Trypanosoma congolense*, the cause, both directly and indirectly, of a vast amount of impoverishment. The most effective chemotherapeutic agents for this disease yet described in the literature are phenanthridinium compounds[1] having the general structure (I), in which two of the substituents are amino-groups and the third is a hydrogen atom.



I



II



III

In view of the somewhat complex nature of such molecules, and of the difficulty of introducing amino-groups into any selected combination of positions, we have sought to ascertain whether trypanocidal activity is retained in simplifications of the phenanthridinium molecule, and have synthesized quaternary salts of a variety of mono- and di-amino-cinnolines, -quinazolines and -quinolines. In contrast to the highly active phenanthridinium compounds, our bicyclic heterocyclic quaternary salts have little or no trypanocidal action, and a possible explanation of this loss of activity is that the molecular weights of the cations of these bicyclic salts may be below the minimum necessary for activity.

Two of the compounds prepared during this investigation were 4 : 6-diamino-1-methylcinnolinium iodide (II; $R_1 = NH_2$; $R_2 = H$), m.p. 273–274° (found: C, 35·6; H, 3·7; N, 18·5; I, 42·2; $C_9H_{11}N_4I$ requires C, 35·75; H, 3·7; N, 18·5; I, 42·05 per cent), and its 3-methyl analogue (II; $R_1 = NH_2$; $R_2 = Me$), m.p. 283–284° (decomp.) (found: C, 36·0; H, 4·55; N, 16·8; $C_{10}H_{13}N_4I,H_2O$ requires C, 35·9; H, 4·5; N, 16·75 per cent). The constitutions of these compounds were established by the synthesis of each of them by two different procedures, and both these diamines were inactive in the pure state. However, the crude reduction products of the corresponding 6-nitro-salts (II; $R_1 = NO_2$; $R_2 = H$ and Me) (which were intermediates in one of the methods of synthesis) showed definite activity; the trypanocidal power varied considerably according to the conditions used for reduction, the most favourable result being a chemotherapeutic index of about 2 against *T. congolense* in mice (maximum tolerated dose about 4·5 mgm., intraperitoneally; minimum curative dose about 2·25 mgm. per 20 gm. body weight) obtained with a crude reduction product of II ($R_1 = NO_2$; $R_2 = Me$). Tested by the same technique, the two best-known phenanthridinium compounds, 'dimidium bromide' ('1553') and 'phenidium chloride' ('897') gave indices of about 15 and 3, respectively.

The observed trypanocidal activity is seemingly due to the incidence of side-reactions accompanying the conversion of the nitro- to the amino-quaternary salts; and, assuming that the same side-reaction is responsible for the development of activity in each of the two cases, the active components may possibly be the azo-compounds (III; $X = 6 : 6'$—N=N). On grounds of analogy, also, there is some reason for anticipating that structures such as (III) may be active, because one of the striking features of many non-arsenical trypanocidal compounds is that they are symmetrical molecules containing two identically constructed cyclic units (for example, diamidines, trypan red, suramin, surfen C, and Bayer 7602 Ac).

Our work is being continued along lines suggested by these observations. If our anticipations prove to be correct, this would indicate the desirability of synthesizing and examining a series of compounds of type (III), with variations in the linkage X as well as in the nature of the two quaternized heterocyclic units.

The steps leading to the finding of trypanocidal activity in compounds of type (III) would provide an interesting parallel to the course of events in quite a different field, that of synthetic sex hormones. The sequence leading to the discovery of œstrogenic activity in symmetrical compounds of the type of stilbœstrol (V) consisted in exploring simplifications of the naturally occurring *cyclo*pentenophenanthrene type of compound, followed by the demonstration of activity in crude preparations of anol (IV); purified preparations of (IV) were, however, found to be inactive, and the activity of the earlier crude preparations was then shown to be due to their contamination by (V)[2,3,4].

Effect of Under-nutrition in Man on Hepatic Structure and Function

DURING August 1946 investigations were carried out on twenty-one civilian citizens of Wuppertal, an industrial German city south of Essen. For at least three months the official rations had not provided more than 35 gm. of protein, 15 gm. of fat and 176 gm. of carbohydrate a day, a total of 1,050 calories. Most of the subjects had been on short commons for twelve months. They were all under-nourished and had lost 6–46 per cent of their body weights. All stated that they had had nutritional œdema, and in sixteen this was clinically detectable. There was nothing in their clinical histories or examinations to suggest hepatic dysfunction. Their livers were not enlarged and no examples of gynecomastia, spider nævi or palmer hyperæmia were encountered.

Liver tissue was obtained from each subject by aspiration biopsy[1]. Histologically this tissue was generally normal, and there were no signs of necrosis, cirrhosis or fatty change. The liver cells sometimes contained considerable amounts of iron and chromolipoid pigment. Diminished blood volumes and low concentrations of hæmoglobin were found in these under-nourished subjects. There was, therefore, a withdrawal of hæmoglobin from the circulation with the liberation of much iron. Moreover, muscle myoglobin, released as muscles waste, may have provided further free iron. Iron in excess of immediate requirements cannot be excreted to any extent[2], and is stored in the liver. The hepatic siderosis observed in these subjects was never of the same extent or distribution as that reported in malnutrition in South Africa[3]. 'Ceroid' pigment was not present in the liver.

The urinary urobilinogen was often increased, and the fæcal urobilinogen diminished. The serum total bilirubin was within normal limits, and the bromsulphthalein excretion test gave normal results. Hepatic glycogen estimated quantitatively, fasting blood sugar concentration, oral glucose tolerance, adrenalin tolerance, and insulin sensitivity tests were all normal. Alkaline phosphatase in the liver was normal both in amount and in histological distribution. Serum alkaline phosphatase was also within normal limits.

In fourteen of the subjects the serum taken in the recumbent position contained a concentration of less than 6·0 gm. of protein/100 ml. The serum colloidal gold reaction was usually negative. The concentration of total serum cholesterol was often low. The percentage of the total cholesterol in ester form was also low. The intravenous hippuric acid synthesis test gave normal results.

The subjects had been living for about a year on a diet the protein content of which was low and mainly of vegetable origin. The intake of lipotropic compounds (which are mainly in and associated with animal protein) must have been diminished. We have failed, however, to demonstrate the hepatic necrosis, cirrhosis or fatty change produced in experimental animals by low dietary protein or a deficiency of lipotropic compounds. Correlation of our results with recent reports of malnutrition in the Far East and elsewhere, and in experimental animals, is extremely difficult. The present report refers only to the effects of under-nutrition on one group of Europeans in one town in Germany, at one particular time, namely, August 1946.

The detailed results of this work will be given in a Medical Research Council Special Report now in preparation.

Isolation of Stilbœstrol Monoglucuronide from Human Urine

IN a recent letter[1] in *Nature*, Dr. A. E. Wilder Smith reports that he finds, by indirect methods, that about 50 per cent of stilbœstrol administered to human beings is excreted as a monoglucuronide. He was, however, unable to isolate this conjugate from the urine of patients treated with the drug. Although stilbœstrol monoglucuronide has been isolated[2,3] from the urine of rabbits receiving relatively large doses of stilbœstrol, it has never been isolated from human urine owing to the small doses normally used. We have now succeeded in isolating a glucuronide of stilbœstrol from human urine and proved it to be identical with that obtained from rabbit urine.

Through the courtesy of Prof. T. N. A. Jeffcoate, we have been able to obtain urine from two women immediately after parturition, who had received, in 24 hours, five 4-hourly doses of 20 mgm. of stilbœstrol. From this urine we were able to isolate the benzylamine salt of stilbœstrol monoglucuronide in a pure crystalline state. This salt had melting point and mixed melting point 223° C. and showed $[\alpha]^{20}_{D} = -55°$ ($c = 0{\cdot}2$ in 50 per cent aqueous acetone) and was identical with a sample (m.p. 223° C. and $[\alpha]^{20}_{D} = -55{\cdot}3°$ (in 50 per cent aqueous acetone)) which we had previously[3] prepared from pure stilbœstrol monoglucuronide isolated from rabbit urine. The yield of benzylamine salt corresponded to 35 per cent of the stilbœstrol administered. Small amounts of free stilbœstrol were also detected in the urine.

Preparation of Œstrogens from Urine by Application of High Temperatures

ŒSTROGENIC substances are usually extracted from the urine of pregnant women, pregnant mares or stallions with organic solvents not miscible in water. There are certain disadvantages inherent in this method: large extraction vessels are required; in view of the great bulk of the initial liquid containing the œstrogenic substances in low concentration and the relatively small total interface between the urine and the solvent, a relatively large volume of the latter has to be used; this in turn involves the use of a large distillation apparatus and a high fuel consumption for the evaporation of the solvent from the extract. Moreover, a high proportion of ballast substances which later require separation accompanies the œstrogenic substances in the extract.

We found the following process helpful for the concentration and preparation of œstrogens: evaporate the initial liquid until a sticky, gum-like residue is left; and heat the residue to a temperature not exceeding 245° C. for five minutes so as to carbonize the bulk of the ballast substances, while substantially preserving the œstrogenic substances.

Extracts of the carbonized mass with organic solvents contain the œstrogenic substances in rather high concentration, so that the evaporation is a step of only minor importance. Owing to the virtually complete destruction of the ballast substances by the heating, the dry residue remaining after the evaporation of the solvent already possesses a high degree of purity. It can, of course, be further purified by the known methods.

None of the usual œstrogenic substances, such as œstrone, œstradiol, œstriol, hippulin, equilin, equilenine, and the like, are destroyed by the procedure of heating.

A Rapid Method for the Estimation of Pregnanediol

THE presence in urine of pregnanediol can be detected easily and rapidly by the following procedure, elaborated in the course of recent investigations and based upon protection of pregnanediol by zinc dust during acid hydrolysis, thereby also preventing discoloration affecting the final colour reaction.

To 100 ml. of urine are added 1·5 gm. of zinc dust and the mixture is brought to the boiling point. Concentrated hydrochloric acid (10 ml.) is added and the mixture is boiled for five minutes. The flask is immersed in cold water, when the zinc dust settles rapidly; the supernatant fluid is then decanted on to a sand column. The zinc retained in the flask is washed successively with 25 ml. *N*/1 hydrochloric acid, 25 ml. *N*/10 hydrochloric acid and three lots of water, each 25 ml.

The washing fluids are also decanted on to the sand column after the zinc has settled. The sand column is dried by sucking hot air through it. The zinc dust retained in the flask is shaken up with about 20 ml. hot alcohol (95 per cent), and the hot extract is decanted on to the sand column. As an appreciable proportion of pregnanediol is retained by the zinc dust, the hot extraction has to be repeated three times. The alcohol is passed rapidly through the sand and the filtrate is evaporated to dryness. The residue is redissolved in 5 ml. alcohol (95 per cent), to which 20 ml. of *N*/10 aqueous caustic soda are added. After standing for one hour in the cold a precipitate forms, and this contains the pregnanediol fraction; it is collected on a fritted glass filter, washed with water and dried. About 10 ml. of hot alcohol are then slowly passed through the filter.

The filtrate may be used for the Gutterman colour reaction. For this purpose it is evaporated to dryness and the residue is dissolved in 5 ml. of concentrated sulphuric acid. In the presence of not less than 0·5 mgm. of pregnanediol per 100 ml. of urine a deep yellow or orange colour develops rapidly. In the absence of pregnanediol, the solution is pale yellow or colourless.

The method may be adapted to quantitative estimations by the use of larger quantities of urine and gravimetric methods. In a series of cases, 24- or 48-hour specimens of urine were divided into portions and pregnanediol was determined quantitatively both by Astwood and Jones' method and by the method described above, utilizing gravimetric and colorimetric procedures. Similarly, weighed samples of sodium pregnanediol glucuronidate were subjected to hydrolysis, pregnanediol being recovered by the two methods. It was found that the sand–zinc method gives yields of practically the same order as the Astwood–Jones method. The sand–zinc method is rapid and easy to carry out. It has been found useful in replacing the established but laborious methods in the diagnosis of pregnancy, impending miscarriage and other clinical conditions for which the detection of pregnanediol is required.

It is hoped to publish the work on which this method is based, along with some account of the cases to which it has been applied, in fuller detail elsewhere.

Higher Fatty Acid Dehydrogenase of Mammalian Liver

AN enzyme dehydrogenating higher fatty acids has been described by several workers, including Lang and Mayer[1] and Annau *et al.*[2]. Lang and Mayer showed that adenylic acid activated such a system in rat liver, while Annau *et al.* showed that hypoxanthine similarly activated a fatty acid dehydrogenase of ox liver.

In order to elucidate the mechanism of the dehydrogenation, the purification of the responsible enzyme system has been attempted, but without appreciable success. Some experimental results obtained during this work, however, may be not without interest.

After dialysis against distilled water, both the preparations previously described[1,2] have now been shown to require coenzyme I, or at any rate a factor present in 45 per cent pure preparations[3] of the coenzyme. The purine or nucleotide activator is also required. Previous workers have reported that the enzyme activity is lost after standing for three days at 0° C., but with added coenzyme I the activity has been demonstrated after dialysing for ten days at 0° C.

REQUIREMENT FOR COENZYME I AND THE EFFECTS OF HYPOXANTHINE AND ADENYLIC ACID AS ACTIVATORS

Expt.	Activator (0·25 μmole of each compound)	Coenzyme I (45%)	Reduction times (min). With lauric acid (t_1)	Reduction times (min). No lauric acid (t_2)	Dehydrog. activity = 100 ($1/t_1 - 1/t_2$)
1	—	1 mgm.	24	27	0·5
2	Hypoxanthine	,,	7·1	15	7·3
3	,,	none	>50	>50	—
4	Adenylic acid	1 mgm.	7·0	10	4
5	,,	none	>50	>50	—
6	Hypoxanthine and adenylic acid	1 mgm.	6·0	8·5	4·5

A convenient source of enzyme is the dialysed aqueous extract of acetone-dried rat liver (1 ml. ≡ 40 mgm. dry wt.). The reaction velocity is measured by the rate of anaerobic reduction of methylene blue at 38° C. The stopper of the Thunberg tube contains 0·2 ml. of 1 : 2,000 methylene blue, while the tube itself contains 1·0 ml. enzyme, 1·5 ml. 0·02 *M*-lauric or palmitic acid emulsion in 0·15 *M*-potassium phosphate, *p*H 7·5, 20 μgm. hypoxanthine or adenylic acid and 1 mgm. coenzyme I preparation in a total volume of 3·0 ml. A control tube is otherwise identical except for the omission of fatty acid. To ensure that the two tubes are comparable, the *p*H values are checked by the glass electrode after the reduction of the methylene blue.

Added diaphorase has not been found to be necessary, but, assuming that the dye is reduced by the coenzyme I—diaphorase hydrogen—carrying system, there is sufficient diaphorase activity in the enzyme preparation to account for the slow reduction observed.

Hypoxanthine is a better activator than an equivalent amount of adenylic acid, adenosine di- or triphosphate, or xanthine. Uric acid and allantoin are inactive. The effects of adenylic acid and hypoxanthine are not additive, and since Kalckar[4] has shown the formation of hypoxanthine from adenylic acid in a similar enzyme preparation, it is reasonable to suggest that there is but one dehydrogenase system activated by hypoxanthine or a closely related compound.

In several repetitions of the preparation described by Annau, the high but variable recorded activities could not be repeated, even after dialysis and the addition of coenzyme I and diaphorase.

The use of dyes of higher redox potential than methylene blue (for example, 2 : 6 dichlorophenolindophenol and indophenol) did not affect the rate of decolorization.

The optimum *p*H is between 7·0 and 7·7. Kinetic measurements are not easy to interpret because of the relatively high 'blank'.

The enzyme system is soluble after prolonged dialysis against distilled water, and no activity is sedimentable on centrifuging at 10,000 × *g* for twenty minutes. 2×10^{-3} *M* sodium cyanide inhibits 40 per cent, while 3×10^{-4} *M* ammonium vanadate, 3×10^{-6} *M* chloracetophenone, 6×10^{-3} *M* hydroxylamine, 10^{-4} *M* oleic acid and 4×10^{-6} *M* silver nitrate inhibit completely.

Enzymic Action of Viruses and Bacterial Products on Human Red Cells

HUMAN red cells incubated with a broth culture filtrate of *V. choleræ* acquire three new properties: they become panagglutinable[1]; they are no longer agglutinated by viruses of the influenza group[2]; and in the case of rhesus-positive cells, they become agglutinable by the corresponding incomplete *Rh*-antibody[3]. The finding that the influenza and Newcastle disease viruses produce the same three reactions on red cells[2,4] has stimulated further study of this phenomenon.

Appropriate human red cells were incubated at 37° C. for an hour with both a suspension from agar culture and supernatant from centrifuged broth culture of a number of bacteria. After washing and resuspension, the red cells were tested for virus hæmagglutination with influenza *A* (*PR* 8), influenza *B* (Lee), swine influenza (Shope) and Newcastle disease virus (Doyle), and for panagglutination by mixing them with serum from the same donor. The *Rh* test was performed either with serum containing incomplete anti-*D* antibody diluted beyond its panagglutination titre, or by suspending cells sensitized with anti-*D* and washed, in the bacteria products.

A survey of more than sixty organisms showed tha a number of bacterial species produce the active sub stance. Besides *V. choleræ*, potent preparations producing all three reactions have been obtained fron *V. proteus* and pneumococcus irrespective of type o virulence. Other organisms, including one strain eac of *Streptococcus* Group *D*; *Streptococcus viridans* *Staphylococcus albus*, *aureus* and *citreus*, *B. subtilis* *B. mycoides*, *Erysipelothrix rhusiopathiæ*, *Erysipelothrix monocytogenes* and *Salm. choleræ-suis*, eithe produce panagglutinability alone, or also weake hæmagglutination by some viruses, but are withou appreciable effect on red cells sensitized with incomplete anti-*D* antibody. Both bacterial suspensions and broth supernatants bring about these changes, although to somewhat different extent with different organisms. The different behaviour of different bacteria may be due to minor differences in the range of their substrates, or may be merely quantitative, depending on the differing sensitivity of the three tests. If the latter assumption is true, then the panagglutination test appeared to be most sensitive, the virus test came next and the incomplete anti-*D* test the least sensitive.

A preparation of concentrated and semi-purified enzyme from *Cl. welchii* type *B*, capable of destroying blood group *O*, *A* and *B* substances, was kindly supplied by Dr. W. T. J. Morgan and was found to produce all three changes in human red cells. These changes in red cells can be completely prevented by the previous addition of blood group *O* substance, and less completely so by *A* substance, both prepared from human ovarian cyst and hereafter referred to as human *O* substance and human *A* substance respectively. The same preparation of enzyme also inactivates the 'Francis inhibitor'[5] present in human *O* substance. These results do not necessarily mean that the same enzyme which destroys the *O* activity is also responsible for the red cell changes and inactivation of 'Francis inhibitor'. According to Morgan[6], the blood group *O* enzyme resists heating at 56° C. for thirty minutes, whereas heating in the same circumstances completely destroyed the activity on red cells and on 'Francis inhibitor'.

The enzymic nature of the process seems to be amply established by accumulated evidence. Freidenreich[1], in a detailed study of the panagglutination phenomenon produced by *M* and *J* diphtheroids and *V. choleræ*, concluded that the process is probably enzymic in nature. All these agents (cholera filtrate, *welchii* enzyme and viruses) are first adsorbed on to, and then released from, red cells, requiring an induction period which in the case of viruses can be studied by the visible agglutination and elution reactions. The active principles are either very thermolabile or moderately so. Thus, pneumococcus and cholera filtrates were greatly weakened after heating to 56° C. for half an hour, while the Newcastle disease virus and *welchii* enzyme were completely destroyed at this temperature. Red cells treated with heat-inactivated enzymes gave negative results by all three reactions.

Since the three reactions of red cells are produced by preparations derived from widely different sources, and since all three are simultaneously prevented by inactivation of the enzymes at a given temperature, it seems most probable that each preparation contains a single enzyme responsible for the production of all three reactions. This explanation is strengthened in the case of *welchii* enzyme by the observation that all three activities are inhibited by the presence of human *O* or *A* substance. Burnet, McCrea and Anderson[7] have reported that both cholera filtrate and influenza viruses destroy the 'Francis inhibitor' present in crude mucin and purified blood group *O* and *A* substances, without, however, altering the immunological specificity of *A* substance, which was the only one tested. The presence of 'Francis inhibitor' in human *O* substance, and to a much less extent in human *A* substance, has been confirmed. However, a mixture of blood group *A* and *O* substances purified from hog gastric mucin and containing comparable *O* activity to that of *O* substance from a human source has no 'Francis inhibitor' activity even at 0·1 per cent concentration.

I have also found that influenza *B* virus, Newcastle disease virus, cholera and pneumococcus filtrates, although capable of destroying the 'Francis inhibitor' property of human *O* substance, nevertheless have no significant effect on its immunological activity. Furthermore, their action on red cells is not inhibited by the presence of either human *O* or *A* substance. These findings seem to suggest that the blood group substances *per se*, as defined immunologically, are not the true virus receptor substance. A fuller report will appear elsewhere.

Choleglobin Formation in the Erythrocyte

The pioneer researches of Lemberg and his co-workers[1] have provided a new approach to the problems of hæmoglobin breakdown and bile pigment formation. Using his methods, we have recently re-examined the question of the occurrence of the intermediate choleglobin in the intact erythrocyte.

To determine the quantity of choleglobin present, the pigment is disrupted by 66 per cent acetic acid to biliverdin, which is extracted with 5 per cent hydrochloric acid, and measured colorimetrically. During the acetic acid treatment, further oxidation of biliverdin to biliviolin was observed, but Lemberg was able to prevent this change by addition of 10 mgm. ascorbic acid as antioxidant. It appeared to us that this procedure might lead to error, since choleglobin is itself formed rapidly by coupled oxidation of ascorbic acid with oxyhæmoglobin.

In the present work this difficulty was avoided by carrying out the whole Lemberg procedure in an apparatus that could be completely evacuated or filled with an inert gas, so that all the reactions could be carried out in an oxygen-free atmosphere. In this way, the following side-reactions were inhibited: (1) formation of choleglobin from oxyhæmoglobin by coupled oxidation with intracorpuscular ascorbic acid or glutathione; (2) oxidation of biliverdin to biliviolin by atmospheric oxygen, or by active oxygen liberated by acid denaturation of oxyhæmoglobin; (3) conversion of choleglobin to 'green pigment'.

Lemberg and Legge[2] have observed that normal human red blood corpuscles contain 1–5 μgm. biliverdin per c.c. combined as choleglobin.

In our anærobic experiments no choleglobin could be detected in a series of twelve separate samples of normal human blood, nor in blood samples taken from patients suffering from pernicious anæmia, leukæmia, hæmolytic anæmias, hepatic and obstructive jaundice, or polycythæmia, with the following exceptions: in one case of leukæmia we found 0·4 μgm. of biliverdin per c.c., while in one case each of pernicious anæmia and obstructive jaundice (pancreatic carcinoma) the concentration of pigment was at the lowest limit of optical measurement.

It would appear, therefore, that choleglobin production from oxyhæmoglobin does not take place in the normal erythrocyte, and this and subsequent changes to form biliverdin can only ensue after disruption of the corpuscle.

Origin of Noble Sugar-Canes (*Saccharum officinarum* L.)

The cultivated sugar-canes belong to two main groups: (1) the thin and hardy types of north Indian canes botanically classified under *Saccharum Barberi* Jesw. and *Saccharum sinense* Roxb.; and (2) the thick or noble types, *Saccharum officinarum*. The origin of these noble canes is still obscure, and Barber[1] and Jesweit[2] were of opinion that it was in the mountainous islands of the Malayan Archipelago, New Guinea and Polynesia. It is considered that these types of cane were introduced into India only very recently and are referred to as 'the introduced canes', while the north Indian canes are held to be indigenous to India and any mention of sugar-cane in India in early historical records or mythological legends is believed to refer only to north Indian canes.

Cytogenetical studies[3], supported by morphological evidence, have indicated that the north Indian canes are complex polyploid hybrids derived from the extensive natural hybridization of *S. officinarum* with *S. spontaneum* L., a related wild species which has a geographical distribution extending from the slopes of the Himalayas down to the tropical plains of Sumatra and Java. Therefore, it was concluded that the north Indian canes are of a later origin than the noble canes and that the thick canes must have been in cultivation in India earlier than the 'indigenous' or north Indian canes.

Studies are now in progress to identify the fundamental species composition of the noble cane, *S. officinarum*, which is considered to be an octoploid ($2n = 80$) with a basic number $x = 10$ characteristic of Andropogoneæ[4]. In interspecific and intergeneric hybrids with *S. officinarum* it is found that the haploid complement ($n = 40$) of *S. officinarum* pairs auto-syndetically to the exclusion of pairing between parental chromosomes. This was to be expected owing to the polyploid composition of the haploid complement itself. When, however, the chromosome complement of *S. officinarum* was reduced to the diploid and haploid number by successive back-crossing with the *Sclerostachya fusca* A. Camus, a wild species of a related genus, the homology between parental chromosomes began to manifest itself. Thus, with the diploid number, although ten bivalents of *S. officinarum* were commonly noticed, a certain number of multivalents resulting from the pairin of parental chromosomes were also noticed. In th haploid state it was clearly noticed that five chromosomes of *S. officinarum* invariably paired with five o the other parental species, thereby showing homolog between them.

One of the types of the noble class of canes, namely *Vellai* ($2n = 80$), was crossed with *Sclerostachy* ($2n = 30$) and the hybrid was successively back crossed with the same wild species. The accompanying table gives in the main the analysis of chromosome associations at metaphase I of meiosis in th derived hybrids.

Association of chromosomes at metaphase I

	$2n$ (number)	No. in the species complements of hybrids		Pairing at metaphase I
		S. officinarum (*O*)	*Sclerostachya fusca* (*S*)	
Parents:				
S. officinarum (Vellai)	80			40^{II}
Scl. fusca	30			15^{II}
Hybrids:				
F_1 hybrid	55	40	15	$20^{II}(O) + 5^{II}(S) + 5^{I}(S)$
F_1 × *Scl. fusca* (back-cross I)	70	40	30	$20^{II}(O) + 15^{II}(S)$
B.C. I × *Scl. fusca* (back-cross II)	50	20	30	$10^{II}(O) + 15^{II}(S)$ $5^{III}(O+S) + 15^{II}(O+S) + 5^{I}(O)$ $2^{IV}(O+S) + 21^{II}(O+S)$
B.C. II × *Scl. fusca* (back-cross III)	40	10	30	$5^{III}(O+S) + 10^{II}(S) + 5^{I}(O)$

The basic number of ten chromosomes is now seen to be really constituted of two different sets of $x = 5$ chromosomes each, one set of which is common to both *Sclerostachya* and noble cane. A detailed account will be published elsewhere. The identification of these fundamental complements now remain to be investigated through a series of interspecific and intergeneric crosses by the utilization of the back-cross hybrids with the reduced complement of *S officinarum*.

It is interesting to note that *Sclerostachya fusc* was originally included in the genus *Saccharum*[5], and later was separated as a different genus. This specie is found widely distributed in India from Kashmi to Bengal and Assam and also in the Western Ghats It is clear from the above studies that *S. officinarun* and *Sclerostachya* have had a common ancestry through an unidentified basic species with $x = 5$ chromosomes. This would lend further support to the view that *S. officinarum* has been in existence in India from very early times and that it playec a part in the evolution of the north Indian or indigenous canes.

Occurrence of the Amphipod *Orchestia bottæ* and Other Organisms in Britain

The range of *Orchestia bottæ* M. Edws. is greater than that indicated by Messrs. Cain and Cushing[1]. Besides the records from the Thames, I have specimens given me in 1945 by Mr. A. E. Ellis from the River Yare at Brundall, Norfolk. In 1947 I received specimens from the same area, but taken from much higher up the river, about twenty miles from the sea. In fact, it seems possible that this species is widely distributed throughout south-east England, and that recent discoveries disclose an established range rather than a late immigration from the Continent.

A similar case is that of *Eucrangonyx gracilis* (S. I. Smith), specimens of which I have from the Metropolitan Water Board's works at Lee Bridge; from a garden pond at Harrow (on the water system of the Colne Valley Water Co.); from ponds in Surrey; and lastly, in great abundance, from among floating dead leaves in a small backwater of the River Cherwell at Oxford in 1944.

Gammarus lacustris G. O. Sars has long been known to have a wide range in Scandinavian and other Continental fresh waters, and yet has only been discovered in Britain comparatively recently (1939). Despite this late discovery, persistent search has shown the species to be established in very many lochs in the north of Scotland, and so one concludes that it is really an old inhabitant.

In other words, it is not necessarily the range of some of these animals, I believe, that is increasing, but our knowledge of their range.

Discovery of Radioactivity

In *Nature* of January 3, a review entitled "Atomic Energy" by Prof. J. A. Crowther referred to the progress made "since the spontaneous release of atomic energy fogged a packet of photographic material in the drawer of Becquerel's desk".

This sentence seems to imply that the discovery of radioactivity by Henri Becquerel, my father, in 1896, was fortuitous—which is incorrect. He intentionally subjected a photographic plate—not a "packet"—to the action of salts of uranium. His first idea was that phosphorescence of uranyl salts might be accompanied by a radiation similar to X-rays, which had just been discovered. Instead of rays associated with phosphorescence, Henri Becquerel found a new spontaneous radiation, emitted by all uranium compounds, phosphorescent or not, and he established that this radiation was an atomic property.

Hence it is undesirable that any idea of radioactivity being discovered by chance should arise.

Jean Becquerel

Muséum National d'Histoire Naturelle
et École Polytechnique,
Paris.

I am surprised that Prof. Becquerel should have read into a passing reference to his distinguished father's work, in my review of Prof. Gamow's book, a suggestion that the discovery of radioactivity was in any way "fortuitous". No such suggestion was intended. I had always imagined that the historic photographic plate was enclosed in some sort of light-proof wrapping, and might be legitimately, if briefly, described as a "packet of photographic material".

J. A. Crowther

Operational Research

In his admirable article on operational research in *Nature* of March 13, Sir Charles Goodeve makes the statement: "The application of the statistical tool is still on the increase, but there is no need or likelihood of the tool itself being developed further". Quite apart from the dangers inherent in making general prophecies about the likely advance (or lack of advance) in any field of science, this statement implies a degree of perfection in existing methods of dealing with statistical problems arising in operational research which would not, I think, be claimed by practising statisticians. In particular, the analysis of data (such as survey data) which can be classified in a number of different ways, and multivariate analysis, both require further development.

In the analysis of survey data it is often of considerable importance to determine differences between the different classes of any one classification, free from the disturbing effects due to disproportionate representation in the other classifications. The basic theory (that of fitting constants by the method of least squares) is well known, but no analytical technique suitable for routine application to extensive data has yet been worked out. In multivariate analysis, which is of the greatest interest in economics as well as in many other fields, progress in both theory and analytical technique may be expected.

The dependence of the development of any given technique of statistical analysis on the availability of suitable machines is often not sufficiently realized. Without the modern desk calculator, the development of the technique of the analysis of variance appropriate to experimental results, and the associated development in the theory of design of experiments, could scarcely have taken place. In like manner, multivariate analysis has been waiting on the further development of machine design which is only now being effected.

With Sir Charles Goodeve I confidently look forward to the introduction of novel methods primarily dependent on advances in other fields of science; but if these are to reach their maximum effectiveness they must be integrated with, rather than regarded as alternatives to, the statistical approach.

F. Yates

Statistical Department,
Rothamsted Experimental Station,
Harpenden, Herts.
March 23.

I am grateful to Dr. Yates for correcting false impressions which may arise from my remark. Operational research as I have seen it has so far found the statistical tool adequate for that side of its work, but I might have guessed that there would always be 'frontiers' with unexplored fields or unsolved problems beyond.

Charles Goodeve

FORMATION AND BREAKDOWN OF SERPULID TUBES

By JEAN HANSON
Bedford College, University of London

DURING an investigation of the blood systems of serpulid worms (Annelida, Polychæta), opportunities occurred to make the following observations on the mode of formation and breakdown of the calcareous tubes in which these animals live.

Although much research has been carried out on the asexual reproduction of *Salmacina* and *Filograna* by Malaquin, Faulkner[1] and others, it is not known how a newly formed individual leaves its parent's tube and makes its own tube. During last summer, specimens of *Salmacina incrustans* Claparède settled on the sides of a glass aquarium in the Zoological Station at Naples, and daily observations were made on the growth of the colonies. The new individual is formed at the posterior end of the parent, and after separation it moves backwards down the parent's tube and makes a hole in the side of the tube from which it protrudes its branchial crown (Fig. 1, *X*). It may destroy the posterior end of the parent's tube and thus separate it from the rest of the colony (*Y*). It may also form a new tube which grows out from the original opening (*Z*). These colonies spread out over the wall of the aquarium. Colonies taken from the sea usually consist of masses of entangled tubes raised off the substratum to which the basal parts are attached. These three-dimensional colonies are built up of tubes with side-branches which are presumably formed in the same way as in the two-dimensional colonies growing in the aquarium.

It is not known how the newly separated bud makes the hole in the side of its parent's tube. One is reminded of the ability of the sabellid *Potamilla* to bore into calcareous rocks[2]. At Naples *Potamilla* often lives inside the walls of the calcareous shell of the mollusc *Vermetus*. How *Potamilla* bores its holes is also unknown. Some observations of Fox[3,4] are interesting in this connexion. He has found that when the anterior end of the tube of *Sabella spallanzanii* is artificially closed, the animal can make a hole in the side of the tube, from which it then protrudes its branchial crown. The tube of *Sabella* consists largely of mucus and is not calcareous.

Alkaline phosphatase is probably concerned in the calcification of bone and in the formation of the calcareous shells of molluscs[5]. It was therefore interesting to find this enzyme in *Pomatoceros triqueter* L. (Fig. 2) which, like the other serpulids, builds a calcareous tube. When *Pomatoceros* is removed from its tube, it begins to form a new one[6]. The new tube first appears on the ventral surface of the anterior part of the thorax under the ventral collar fold. It is not known how this new tube is produced; but it seems likely that it is secreted by glands in this part of the thorax.

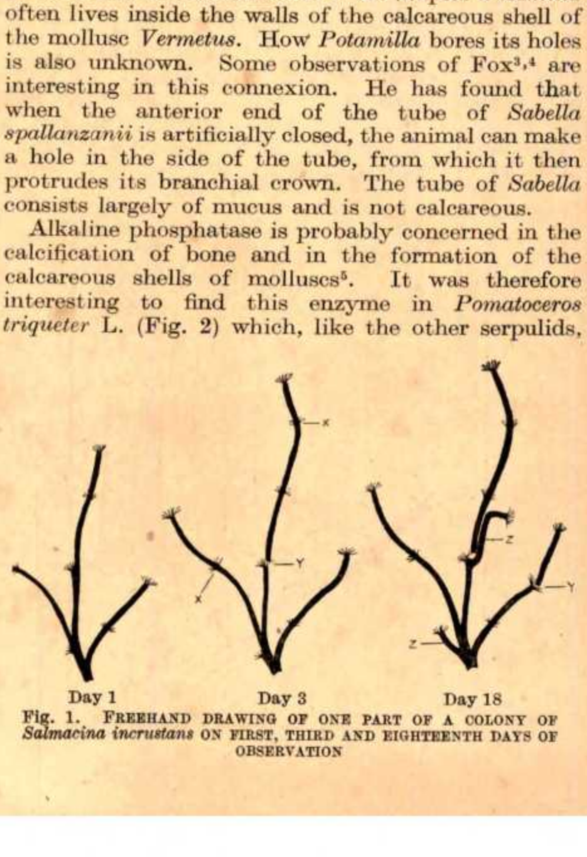

Fig. 1. FREEHAND DRAWING OF ONE PART OF A COLONY OF *Salmacina incrustans* ON FIRST, THIRD AND EIGHTEENTH DAYS OF OBSERVATION

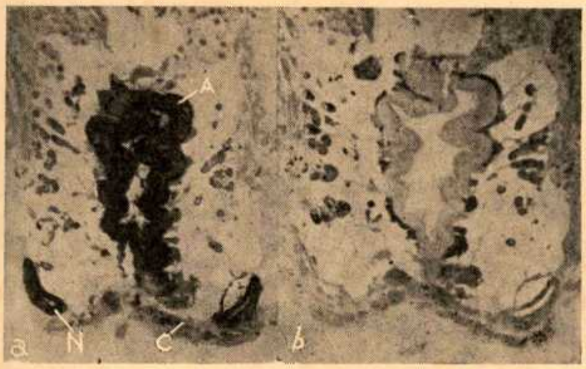

Fig. 2. PHOTOMICROGRAPHS OF HORIZONTAL LONGITUDINAL SECTIONS THROUGH THE THORAX OF *Pomatoceros triqueter*. × 25. (*a*) TREATED BY GÖMORRI'S METHOD FOR ALKALINE PHOSPHATASE (SITES OF ENZYME BLACK); (*b*) CONTROL

One specimen of *Pomatoceros*, fixed immediately after removal from its tube, was sectioned and tested for alkaline phosphatase by Gomori's method[7]. The enzyme was found in the following places:

(1) The epithelium of the alimentary canal (Fig. 2, *A*) from the posterior end of the œsophagus to within a few segments of the anus. This is the part of the alimentary canal concerned with the digestion and absorption of food[8]. Phosphatase was concentrated at the inner and outer borders of the cells and was also found in the nuclei and in small granules in the rest of the cytoplasm. There was a thick deposit of phosphatase on the cilia. Bourne[5] has shown that the enzyme is confined to the absorptive regions of the guinea pig's alimentary canal and is there concentrated in the brush borders of the epithelium. He has discussed the hypothesis that alkaline phosphatase is concerned in the phosphorylation of sugars being absorbed from the canal.

(2) The epithelia of the thoracic nephridia (Fig. 2, *N*) and their ducts. In the excretory sacs of the nephridia the phosphatase was distributed in the same fashion as in the gut epithelium, and was also present on the cilia. Alkaline phosphatase has been seen in the brush borders of the proximal convoluted tubules of the mammalian kidney[7] and in the brush borders of the Malpighian tubules of the goat-moth caterpillar and a spider[9]. Danielli[7] has discussed the suggestion that in the kidney alkaline phosphatase plays a part in the reabsorption of substances from the glomerular filtrate.

(3) The contents of the alimentary canal.

(4) The chloragosomes (yellow- or brown-coloured globules) in the chlorogogen cells which in serpulids lie on the thoracic ring vessels. Globules of similar appearance, also giving a positive phosphatase reaction, are found in the epithelium of the excretory sacs of the thoracic nephridia. According to Liebmann[10] chloragosomes contain food substances, and he has found that in the chloragosomes of the oligochæte *Eisenia fœtida*, phospholipins are transformed into fats, lipoproteins appearing as transitional substances. Alkaline phosphatase may play some part in this process.

A second specimen of *Pomatoceros* was fixed three days after it had been removed from its tube; it had not begun to form a new tube. Alkaline phosphatase was again found in the same four sites as in the other specimen, and also in the following places (Fig. 2):

(5) The borders of small irregular cavities (*C*) situated in the thick epithelium on the ventral surface of the thorax under the ventral collar fold. This is the tissue which probably secretes the calcareous tube, and alkaline phosphatase is perhaps concerned in this process, as it seems to be in the calcification of bone and in the formation of the calcareous shells of molluscs[5].

(6) The epithelium of the dorsal and ventral lips of the mouth.

(7) The nuclei of the endothelium in the walls of the blood vessels in some of the pinnules of the branchial crown. Bourne[5] has found the enzyme in endothelial nuclei of vertebrate capillaries.

I wish to thank the staff of the Zoological Station of Naples, the British Association for the Advancement of Science for the use of its Table, and the University of London for a grant towards travelling expenses. I am also indebted to Dr. A. Stock for advice on the use of Gomori's method.

PLANT VIRUS PROTEINS AND ANTIBODY–ANTIGEN REACTIONS

By R. E. F. MATTHEWS

Plant Virus Research Unit, Molteno Institute, Cambridge

PROTEIN mixtures such as those found in blood have been widely used in the study of antibody–antigen reactions. It is difficult to prepare pure samples of single proteins from such naturally occurring mixtures. On the other hand, preparations of certain plant virus proteins, derived from a single infectious unit, can be isolated in quantities sufficient for experimental work in a state which fulfils all the usual criteria of homogeneity. As they are also good antigens, they would appear to be especially suitable objects for the study of antibody–antigen reactions.

The method used by Boyd[1] has been applied to the study of the turnip yellow mosaic virus antisera produced in rabbits. Successive doses of 0·01, 0·1, 1·0, 10·0, and 100·0 mgm. of turnip yellow mosaic virus[2] (prepared by the method of Markham and Smith[3]) were given intravenously to a single rabbit. Bleedings were taken two weeks after each injection, followed by a rest period of a few days before the next injection.

The antiserum produced by the 0·01 mgm. injection was of low titre with marked suppression of precipitation in the region of antiserum excess. This antiserum would be of the *H* type according to Boyd's classification. With increasing dosage of antigen the antiserum produced gave progressively higher titres, and the type of precipitating system produced tended progressively towards Boyd's *R* type, with less-marked inhibition in the region of antiserum excess.

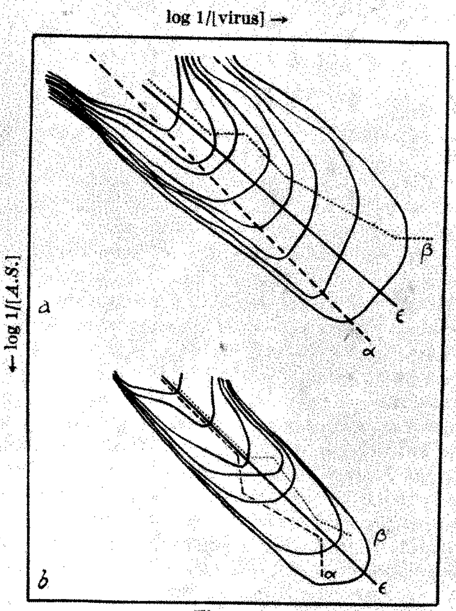

Fig. 1

Fig. 1*a* shows the precipitating system for the antiserum produced after the 0·01 mgm. plus 0·1 mgm. injections. Fig. 2 shows the system for the antiserum from the same rabbit after the full course of injections.

If this antiserum obtained after the full course of injections is diluted with normal serum to make its titre approximate to one of the earlier antisera obtained, then the type of system produced approximates fairly closely to that produced by the earlier bleeding. For example, the antiserum obtained after the full course of injections (with a titre of 1 : 8192) was diluted to 1 : 256 with normal serum and a precipitation diagram prepared (Fig. 1*b*). This antiserum precipitated to a titre of 1 : 64, and there was fairly marked inhibition in the region of antiserum excess similar in amount to that found for the antiserum of Fig. 1*a* with a titre of 1 : 128.

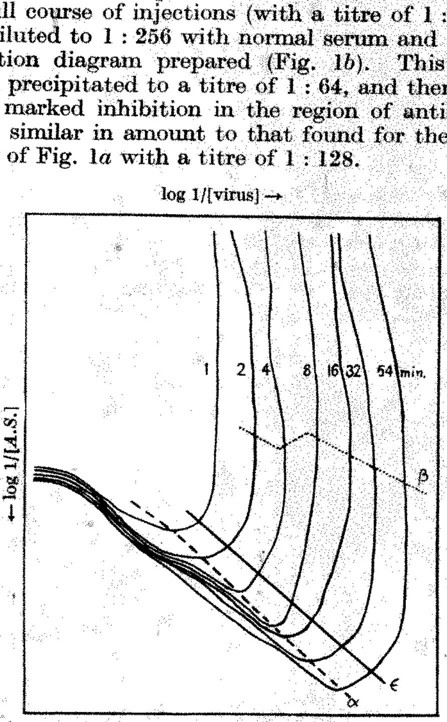

Fig. 2

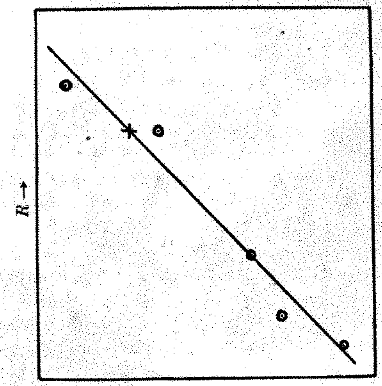

Fig. 3

The lowest concentration of virus which gives a precipitate is in general independent of the antiserum used, at antiserum dilutions where there is no inhibition by antiserum excess. The maximal inhibition by antiserum excess occurs with antiserum at 1 : 1. The ratio between the lowest concentration of virus giving precipitation with antiserum at 1 : 1 to the true virus end-point concentration gives a value for the amount of inhibition by excess antiserum which can be used to compare various antisera.

In Fig. 3 the ratio

$$R = \frac{[V] \text{ for antiserum at } 1:1}{[V] \text{ at real virus end point}},$$

where $[V]$ is end-point concentration of virus in mgm./ml., is plotted against the titre of the antiserum for the five sera used.

The point marked with a cross in Fig. 3 shows the position of the antiserum of Fig. 1*b*.

The inhibition in the region of antiserum excess shown in Fig. 1*b* can be due only to the presence of the non-specific constituents of the normal serum. On this account and in view of the close correlation between titre and amount of inhibition in the region of antiserum excess, it is suggested that the phenomenon of inhibition in the region of antiserum excess, the type of isochrones produced in this region, and the occurrence and position of the β-optimum, can be largely accounted for by some non-specific effect of normal serum constituents, at least in the system under investigation. Any theoretical consideration of the mechanism of this reaction, in the region of antiserum excess, will have to take this fact into account.

Rod-shaped plant viruses give a flocculent *H*-type precipitate whereas the spherical plant viruses give a dense granular *O*-type (Bawden[4]). Advantage has been taken of this fact in an investigation of the type of antiserum produced by a protein mixture. A rabbit was given a single intravenous injection of 1 ml. containing 1 mgm. of turnip yellow mosaic virus plus 1 mgm. of tobacco mosaic virus. An antiserum reacting with both viruses was obtained after two weeks. The same rabbit was given a second dose of 16 mgm. of each virus and a second antiserum obtained, of higher titre. These two antisera were tested against each virus separately, and against a mixture of known amounts of these.

That the two systems were precipitating independently was indicated by the following facts: (1) The position of the two α-optima for the two systems precipitating together was that which could be predicted from the two systems precipitating singly. (2) No significant decrease in titre of the antiserum for one virus was obtained after absorption with the other. (3) In the case of the two systems precipitating together, where the times for precipitation of the two systems were widely different in a single tube, the faster precipitate settled in the tube before the second precipitate formed, so that the latter formed a layer on top of the first.

In tubes where both systems precipitated about the same time, particularly in the higher concentrations, the gross floccules which were observed were homogeneous, and of indeterminate type. In view of the above, it is considered that this may possibly be due to mechanical entanglement of the smaller aggregates.

It is considered that, for the system studied, the antibodies produced in the rabbit are specific for the individual proteins of the mixture injected, and that in the *in vitro* reaction the two systems precipitate independently, except under conditions where the times for precipitation of the two systems are approximately the same, especially with high concentrations of the reagents.

A full account of these and other results will appear elsewhere. I wish to record my thanks to Dr. Roy Markham for his helpful encouragement and criticism.

THE DISORDERING OF β-BRASS BY COLD WORK

By R. W. K. HONEYCOMBE and Dr. W. BOAS
Council for Scientific and Industrial Research, Australia

THE order–disorder transformation in β-brass has received much attention in recent years. However, it has not yet been found possible to obtain the disordered state at room temperature by quenching. Furthermore, an attempt to produce the disordered state by cold work[1] has not been successful, because the maximum amount of deformation which could be given to the pure β-brass was only 9·5 per cent reduction in area by drawing.

Since crystals of β-brass can be very heavily deformed when embedded in crystals of the more ductile α-phase[2], the use of a duplex brass provides a more likely way of producing the disordered state in β-brass. The X-ray method of showing the existence of the super-lattice in the case of β-brass presents great experimental difficulties; consequently we have used the electrical resistivity of the alloy to indicate its state of order. If the order is destroyed by cold work, an increase in resistivity is to be expected, by analogy with experiments which have been made with other alloys[3].

Lengths of duplex brass wire containing 41·3 per cent zinc were annealed for 30 minutes at 800° C., then furnace-cooled to room temperature over a period of 12 hours. This treatment resulted in a coarse structure in which the α- and β-phases were present in approximately equal proportions. The wires were then cold drawn to various reductions in area up to 95·5 per cent, and the electrical resistivities were measured on a Kelvin double bridge within two hours of drawing.

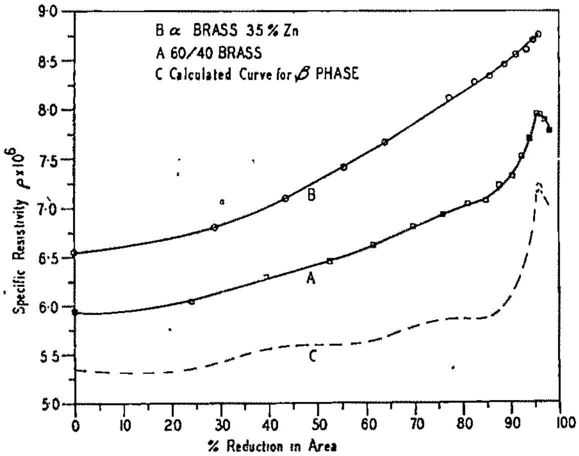

Fig. 1. SPECIFIC RESISTIVITY OF COLD-DRAWN α AND $\alpha + \beta$ BRASS WIRES

In Fig. 1 (curve *A*) the electrical resistivity is plotted against the degree of deformation. The resistivity increases with deformation, at first almost linearly, but more rapidly at higher deformations. After 95 per cent reduction in area, the specific resistivity had increased by about 33 per cent. At still higher deformations the resistivity slightly decreased.

To determine the individual behaviour of the α- and β-phases in the duplex wire, a similar series of measurements was made on a single-phase brass wire containing 35·1 per cent zinc, which is approximately the zinc content of the α-phase in the duplex brass. The results are shown in Fig. 1 (curve *B*). Although the resistivity of the α-brass also increases markedly with deformation, there is no rapid increase after heavy deformations. Assuming that the duplex alloy consists of equal parts by volume of each phase and that the α-phase in it behaves in the same way as the α-phase wire, then the behaviour of a wire consisting entirely of the β-phase can be deduced (Fig. 1, curve *C*). This curve indicates that the resistivity of the β-phase changes little up to 85 per cent reduction in area, where the curve turns steeply upwards. After 95 per cent reduction in area, the curve begins to fall.

In order to ascertain that this increase at high deformations was not a result of cracking, the wires were annealed in hydrogen at 800° C. for 30 minutes and furnace-cooled, that is, they received the same treatment as before deformation. Thus no difference in the distribution of the two phases should have occurred. The results of resistivity measurements on the annealed wires are shown in Fig. 2 (curve *A*), which indicates that all the wires have specific resistivities close to that of the original wire prior to drawing. Moreover, microscopic investigation showed no evidence of cracking, and the mere fact that the wires can be drawn still further points in the same direction. Thus the steep increase in resistivity of the duplex wires after heavy deformations can only be attributed to the disordering of the β-phase. After 95 per cent reduction the β-phase has apparently become completely disordered when further cold work has little effect on the resistivity. That this occurs only after an unusually high extent of total deformation is probably due to the fact that in the duplex alloy the β-phase receives a smaller fraction of the deformation than the ductile α-phase.

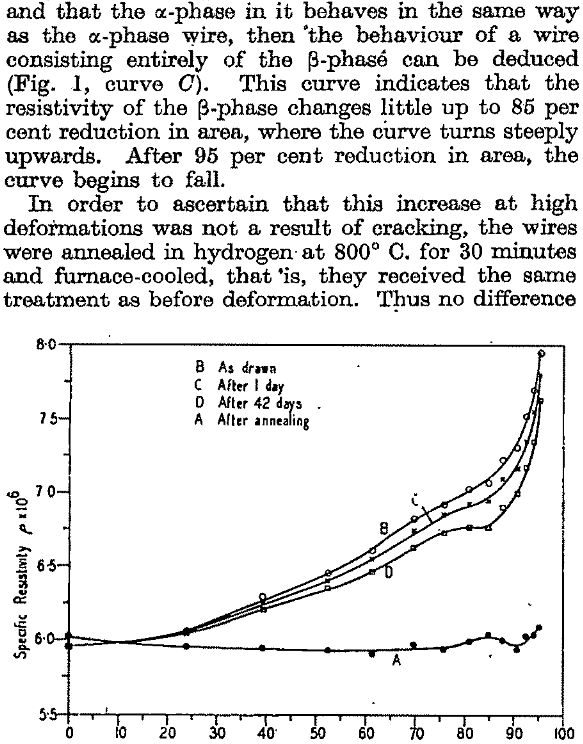

Fig. 2. SPECIFIC RESISTIVITY OF COLD-DRAWN $\alpha - \beta$ BRASS WIRES

The resistivity of the duplex wire decreased with time after drawing. Fig. 2 shows the resistivity on drawing (*B*, corresponding to Fig. 1 *A*) after one day (*C*) and after forty-two days (*D*). It will be seen that after forty-two days the increase in resistivity produced by intensive cold work has decreased by 20 per cent. Further experiments showed that this recovery was in fact complete after twenty-seven days, and a subsequent decrease in resistivity after a period of seventy-nine days was only just measurable. In contrast with these results on duplex wires, α-phase wires showed no pronounced recovery, any decreases being of the order of ½ per cent six days after drawing. It is thus concluded that the β-phase is responsible for the changes in resistivity with time of the drawn duplex brass wires. The disordered state produced in the β-brass is presumably not completely stable, and a certain degree of re-ordering occurs at room temperature.

The marked change in resistivity produced by working a single-phase brass wire (35 per cent zinc) is also interesting. We found that the resistivity of brass wires of other compositions also increased, although that of pure copper did not. This fact is in contrast to statements made in the literature[4] that the electrical resistivities of terminal solid solutions are not affected by cold work. It does not seem improbable that a certain degree of order exists in α-brass and even in other α-solid solutions.

The work described above was carried out as part of the programme of the Section of Tribophysics, of the Council for Scientific and Industrial Research, Australia.

ROOFS SUPPORTED BY AIR PRESSURE

By HERBERT H. STEVENS, JUN.
1270 Sixth Avenue, New York 20

ROOFS supported by air pressure are being seriously considered for long-span building construction as the result of tests conducted at New York University for the United States War Production Board in 1944.

Flat, circular membranes, fixed around the periphery, were stretched above the elastic limit by air pressure to shallow dome shape, and were tested for load-bearing properties and stability at slight, continuously maintained pressures. Neither unsymmetrical loading on sheet steel models up to 12 ft. in diameter nor wind-tunnel tests disclosed undesirable features.

Besides theoretical studies of stress and strain distribution in the membrane, construction features and experience obtained with actual pressure-supported roofs were investigated. One of these structures was a semi-cylindrical roof, 25 ft. radius, 200 ft. long, built of 22-gauge sheet steel on formwork which was supplanted by 0·5 lb. per sq. in. air pressure after the ends were closed with a flexible connexion and the floor rendered airtight. This structure was built in 1934 at Minneapolis and was used as a 70,000-bushel grain bin for a year, after which it was dismantled because grain dust in suspension constituted an explosion hazard. Another structure investigated was a series of flexible-roofed inflated gas holders built of thin steel plates up to 300 ft. in diameter.

Because air-supported roofs offer enormous spans with the minimum of structural materials, they have caused considerable interest. The aeroplane manufacturer, Glenn L. Martin, proposed an 800-ft. diameter roof for a football stadium at Baltimore in 1945, shortly before the construction of amusement structures was forbidden by the U.S. Government. This roof was to have been of 52–SO aluminium alloy 0·109 in. thick with welded seams, and was to be supported by 0·06 lb. per sq. in. (gauge) air pressure maintained by ordinary ventilating fans discharging into the enclosure formed by the walls and ground. Entrance and exit were to be by revolving doors, and means were included for raising the pressure to balance snow loads and to supply power in case of power failure. The roof membrane was to be anchored to a concrete compression ring around the periphery of the stadium having sufficient strength to withstand the inward pull of the membrane to its yield strength. The membrane was to be formed by air pressure to finished shape from a somewhat flatter constructed shape. This would relieve stresses in the welded seams and tight spots in the membrane, and constitute a proof test of the structure. The air pressure to do this was calculated to be about 0·22 lb. per sq. in., a pressure of small physiological importance, and one obtainable with the ventilating blowers. This pressure would be about that needed to support 2·5 ft. of snow; and the roof capable of containing this pressure would also be capable of withstanding the lifting effect of a wind velocity of 125 miles an hour. These figures were based on the experiments previously mentioned. It was also found with a flutter model in the wind tunnel that a slight excess pressure maintained in the structure prevents rippling or flutter of the roof.

A number of other buildings using this roof have been considered, although none, so far, has been built. These include smaller structures about 300 ft. in diameter in which the circular anchor ring is carried overhead on columns and the building space extended underneath to fill out the corners of the lot. Structures ranging upwards to 1,800 ft. in diameter for industrial buildings, storage warehouses, commercial and amusement structures where clear span and low cost were important factors have been investigated. It was discovered that such structures could probably be built over the poorest of soils, since the roof loads were evenly transmitted to the floor and not concentrated at the footings. Another factor of interest is that positive pressure within the structure precludes outside air leakage into the building, making exceptional control of the interior atmosphere possible.

A weatherproof transparent plastic of possible use for these roofs is being developed in the United States. If the material, now in pilot-plant construction, is satisfactory, the utility of these roofs would be enormously extended. An unofficial group in Washington, D.C., is investigating the use of a transparent roof over a central courtyard surrounded by a block of apartments for human habitation, and following a suggestion of Prof. J. D. Bernal, a group in Salt Lake City, Utah, is investigating its possibilities for the growing of plants in waterless areas where the moisture may be conserved by the roof. The possibilities of extending the food-growing areas of the world by a technique involving little more than the cost of the plastic and the anchoring means might be of great importance. Likewise the possibility of inexpensively separating large areas from the prevailing atmosphere, and rendering them climatically inhabitable, may have considerable effect in the tropics.

A British Patent 591985 has been allowed on this construction and is endorsed Licence of Right.

PRODUCTION OF AN ANTIBIOTIC SUBSTANCE ON WHEAT STRAW AND OTHER ORGANIC MATERIALS AND IN THE SOIL

By ERNA GROSSBARD

Experimental and Research Station, Cheshunt

MANY soil micro-organisms produce under artificial conditions antibiotic substances which inhibit the growth of certain plant pathogens. On the assumption that a similar process may take place in the soil, investigations on this problem were commenced at the Research Station, Cheshunt, and an attempt made to devise a method whereby antibiotic substances will be produced abundantly in the soil for the purpose of controlling soil-borne diseases. Blair[1], Garrett[2], Millard and Taylor[3], West and Hildebrand[4], Sanford[5], and others, have reported that organic manuring reduced the incidence of certain soil-borne diseases and have suggested that microbial antagonism may be one of the important factors.

Our experiments here have shown that certain micro-organisms known to produce antibiotic substances on synthetic media, such as *Aspergillus clavatus*, *Aspergillus terreus*, *Penicillium patulum* and *Streptomyces antibioticus*, will do so when grown on autoclaved wheat straw to which water has been added[6].

Penicillium patulum has been studied in detail because patulin (clavacin), the antibiotic substance produced by it, has a considerable inhibitory effect on the growth of certain plant pathogens[6,7,8,9]. The organism grew well on sterilized soil, but aqueous soil extracts did not inhibit the growth of the test organisms *Bacterium coli*, *Bacillus mycoides* and *Bacterium phytophthorum*. An antibiotic substance was formed, however, when the fungus was grown on sterilized wheat straw, bracken and sugar beet

TABLE 1

Medium	Diameter of area of inhibition (mean to nearest mm.)
Straw and water	20
Straw and water and 3·5% glucose	27
Sugar beet waste and water	29
Bracken and water	17
Bracken and 3·5% glucose and water	27

TABLE 2

Medium	Inhibition of *B. mycoides* (1 : 10 suspension)	Diameter of area of inhibition
(*a*) Soil and water	None	—
(*b*) ,, ,, and 2·5% straw	Partial	12
(*c*) ,, ,, and 5% straw	Complete	15
(*d*) Soil, water and 2% glucose	Complete	21
(*e*) ,, ,, and 2 5% straw	Complete	26
(*f*) ,, ,, and 5% straw	Complete	28

waste. The addition of glucose (3·5 per cent by weight) increased the inhibitory action of the wheat straw and bracken cultures. The undiluted culture fluid was assayed by the cylinder plate method. The plates were bulk-seeded with a 1 : 10 suspension of *B. mycoides*.

Among plant pathogens inhibited by the culture fluid of *P. patulum* grown on wheat straw and water were *B. carotovorum*, *B. aroideæ*, *B. phytophthorum* and several species of *Phytophthora*. There are indications that a number of other phytopathogens are also sensitive.

Autoclaved composted wheat straw when inoculated with *P. patulum* gave an antibiotic substance only in the presence of glucose. This also applied to peat, and to some extent to fescue, lucerne, mustard and sainfoin. Without glucose, cultures on the four latter materials gave inconsistent results varying with the sample used. In general, the inhibitory agent appeared to be rather unstable. Fescue gave the best results.

Experiments were then made to determine whether an antibiotic substance could be produced within the soil. Fresh wheat straw, 5 per cent, and water, 50 per cent by weight, were mixed with oven-dried soil, autoclaved and inoculated with *P. patulum*. After incubation the liquid expressed from the soil was assayed against *B. coli*, *B. mycoides* and *B. phytophthorum* by the cylinder plate method. It completely inhibited the growth of the test organisms.

A decrease in the quantity of wheat straw reduced the inhibitory action on the test organisms, while the addition of glucose greatly increased it. When straw was omitted and glucose (2 per cent) added, figures were only slightly lower than those obtained, for example, from a soil, straw (2·5 per cent) and glucose (2 per cent) medium (see photograph, Table 2).

It appears that carbohydrate decomposition is an essential factor for the production of an antibiotic substance in sterilized soil by *P. patulum*. A sterilized medium loam such as was used in this experiment may be an adequate substratum for the growth of the fungus; but it does not provide the conditions necessary for the production of an antibiotic substance. Yet as a matter of precaution it should be said that the absence of an inhibitory agent in the liquid expressed from the soil is not conclusive evidence that the antibiotic substance has not been formed at all. At low concentrations adsorption may take place. Garrett, West and Hildebrand, and Sanford have found that the addition of glucose to the soil decreased the incidence of certain diseases. These workers suggested that glucose effected a favourable modification of the microflora of the soil.

Glucose or other sources of carbohydrates such as wheat straw appear to be necessary for the manufacture of an antibiotic substance by *P. patulum*, at least in sterilized soil. It is tentatively suggested that, apart from altering the microflora, glucose may, in addition, induce the production of antibiotic substances in the soil not only by *P. patulum* but also by other micro-organisms.

This work has been carried out with a grant from the Agricultural Research Council. I am greatly indebted to Dr. W. F. Bewley, director of the Experimental and Research Station, Cheshunt, for guidance and advice.

SEISMOLOGICAL RESEARCH IN GREAT BRITAIN

THE report of the British Association Seismological Committee to Section A (Mathematics and Physics) at the Dundee meeting in September 1947 covers a wide field of work during the period 1942–47.

During the war years, much of the time of the staffs of British seismological stations was devoted to war work. At Kew the three Galitzin instruments and the short-period vertical seismograph were maintained continuously. The Wood–Anderson seismographs were discontinued in May 1942, but were restarted for the Heligoland explosion of April 18, 1947. One of these is to be sent on loan to the Royal Observatory, Helwan. The analysis of seismograms is complete to date, and the Kew monthly bulletin, discontinued in May 1940, is being restarted. During the War, information on the recording of flying bomb and other explosions was supplied to Government departments, and help was given to the Admiralty Research Laboratory at Teddington for studies on the correlation of water-waves and microseisms. At Bidston, the seismograph was maintained so far as possible throughout the War, but at times the supply of paper for recording ran out. At Durham, continuous recording ceased from July 1, 1939 until December 31, 1945. The observatories at Aberdeen, Stonyhurst and West Bromwich were kept going by Dr. A. E. M. Geddes, Rev. J. P. Rowland, and Mr. J. J. Shaw, respectively, as has also the Jagger shock recorder at Comrie, thanks to Messrs. W. Macbeth, Bruce, White and Clark. At Edinburgh the seismograph has been maintained in operation throughout the war years, but in view of the pressure of other work no readings from the records have been made since August 10, 1939. Mr. E. W. Pollard has continued his seismograph at Binstead, Isle of Wight.

Natural earthquakes occurred in Great Britain on December 30, 1944, at Skipton in Yorkshire, and at Spean Bridge (Scotland) on Christmas Day, 1946.

Use of Explosives

A Joint Committee of the Royal Society and the Ministry of Supply was formed early in 1946 to investigate the use of surplus explosives for seismological purposes. It was found impracticable to detonate large charges in Britain, but observations have been made on explosions in Germany. Very thorough arrangements were made for the observation of the results of the detonation of about 6,000 tons of explosive at Heligoland on April 18, 1947, and the seismograph records are being studied at Cambridge, in Germany, and by the U.S. Naval Ordnance Laboratory. From Cambridge, also, parties are examining the cross-sections of steep-sided valleys filled with glacial deposits south of Cambridge, in the Lake District and in Wales. A method has also been evolved of carrying out controlled explosions in the water at sea for seismic purposes, but at present there is some difficulty in borrowing a ship.

International Seismological Summary

The work on the International Seismological Summary has now moved from the University Observatory, Oxford, to its temporary home at Kew Observatory, Richmond, Surrey. It is intended that it shall find in due course a permanent home at Cambridge. As the final part of the work from Oxford, Miss E. F. Bellamy, who has just retired, has published an Index Catalogue of Epicentres for 1931–35. This is a supplement to the Index Catalogue 1913–30. The epicentres are arranged by latitude and longitude into four groups: N. and E.; N. and W.; S. and E.; S. and W.; and the date for each shock is given. At the end of the paper two valuable maps on Mollweide equal-area projections are given showing the epicentres. Seismologists will be indebted to Miss E. F. Bellamy, Prof. H. H. Plaskett and the University Observatory at Oxford for the work and for meeting the cost of the printing, also to the American Museum of Natural History for the outline maps. As the first instalment of the work from Kew, the International Seismological Summary for the period January, February, March 1936 has been issued. This contains the readings from observatories, epicentres in geographic co-ordinates and initial times for 116 earthquakes, eight of which are deep-focus earthquakes. The task of bringing this, the final word anywhere on any earthquake, more up to date is formidable. The United Nations Educational, Scientific and Cultural Organisation is expected to contribute funds, and then with sufficient computational assistance the work can be brought as near to date as observatories can send in their final readings of seismograms.

Applied Seismology

In the realm of applied seismology we have the use of the seismograph to obtain news of storms at sea, and in prospecting for minerals, including mineral oil. Both these ways of utilizing seismological methods are being actively employed in Great Britain. The work on the correlation of sea waves and microseisms carried out by the Admiralty has been described by Dr. G. E. R. Deacon, in *Nature* (**160**, 419; 1947); taken in conjunction with the work of the Jesuit Seismological Association, St. Louis, U.S.A., it is a most important piece of work. This work is being followed up by the Admiralty, by the Jesuit Seismological Association and by the U.S. Coast and Geodetic Survey.

Exploration for oil by the seismic method has been going on for some time. Artificially produced earthquakes are sent through the surface layers of the earth, which, if they have sufficiently diverse elastic properties, affect the waves in such a way that, afte making certain assumptions, the character and thickness of the layers may be deduced from the readings of the seismograms. The seismic method i thus used to locate structures such as closed anticlines or domes of porous material likely to contai mineral oil, capped by impervious shale which prevent the escape of the oil. The 'refraction shooting' metho has been used largely in Great Britain, but 'ar shooting' by the Anglo-Iranian Oil Co. was th deciding factor in the opening up of the Eakrin oilfield in Millstone grit sandstones capped by th coal measure shales of Nottinghamshire, which ha produced to date more than 100 million gallons of oil Traces of mineral oil have also been found in th Cretaceous and Jurassic strata in the south o England, but attempts to extract oil from th Mesozoic beds have proved disappointing.

The search for oil by geophysical means ha incidentally discovered new coalfields in Grea Britain. In the search for coal, extrapolations ar carried out from known geological facts, and th likely areas are then surveyed in order by (1) magnetic (2) gravity, (3) seismic methods; and if the are passes all these tests it is then drilled. The magneti survey is quick and easy to carry out, and gives broad outline of the structure provided there is marked magnetic property associated with th structure. The gravitational survey will give an ide of the variation in density in the underlying strat and is rapid and easy to carry out with such instruments as the Frost gravimeter which is, in effect, very sensitive spring balance. The seismic metho takes longer and is more expensive, but gives better idea of the underlying structure.

So far, an extensive coalfield has been verified b boring to 4,000–5,000 ft. in Central Lincolnshire, an it is hoped that the measures will rise as the approach the Wash. Coal measures have bee disproved by a boring at North Creake in nort Norfolk. Seismic surveys have been completed i the vicinity and to the west and south-west Market Drayton in Shropshire, and between he and Burton-on-Trent. Gravity and magnetic survey have been carried out in Wiltshire as an eastern continuation of the Somerset Coalfield, or there may be an independent coalfield, in the Cotswold country of Gloucestershire and in southern Worcestershire, and in certain areas in Oxfordshire—between Oxford and Reading. Work in eastern Essex was also contemplated. In all the above areas there is a possibility of coal being found. Other areas are under consideration, including extensions of present known coalfields.

UNITED NATIONS CONFERENCE ON THE CONSERVATION AND UTILIZATION OF RESOURCES

A REPORT by the Secretary-General of the United Nations, presented as a result of the decision of the Economic and Social Council on March 28, 1947, to call a Scientific Conference on the Conservation and Utilization of Resources, for the purpose of exchanging information on techniques in this field, their economic costs and benefits and their interrelations, recommends that the Conference should be held in the United States during May 16–June 3, 1949. A note on the financial implications is being prepared on the assumption that it will be held at Lake Success; but possibilities of another location are being explored. Four classes of participants in the Conference are contemplated: representatives from Government services, members of non-Government services and individuals selected by member Governments; individual specialists selected with the advice of the Preparatory Committee to prepare papers or to lead discussion, invited by the Secretary-General, in consultation with the Governments concerned; representatives of the United Nations and its specialized agencies; and representatives of interested international organisations and learned societies, and distinguished members of the professions, to be admitted at the discretion of the Secretary-General.

The primary concern of the Conference is with the practical applications of science to public administration and human needs, rather than with minute refinements in research and scientific methodology, and the Conference should serve a uniquely important function by bringing together experts from many related fields. About half the time of the Conference will be given to primary sessions on subjects of general interest such as resource requirements for industrialization, the contribution of improved agriculture to living standards, the planning of multiple use development of regional resources, education in conservation, and the sources and methods for mobilization of capital and man-power for resource development. Technical sessions in the remaining half of the programme will give experts concurrent opportunity of exchanging information on minerals, fuels, power, water, soils, crops, livestock, forests, fish and wild-life, and though primarily devoted to the discussion of methods for the development of natural resources, will reflect the importance in such developments of techniques relating to standards of health and living. Particular attention will be devoted to the special problems of the under-developed countries.

These technical sessions may be expected to stimulate the economic development of such countries by defining the technical knowledge gained in the last decade in determining the resource requirements for various types of industrialization, by exploring the technical problems involved in raising the standard of living by increased agricultural production, by considering the institution of new techniques and by the modification of existing curricula to facilitate the provision of trained personnel in such countries and by directing the attention of the scientific men and technicians of the world to the research and design problems of these areas. A draft programme is being prepared for circulation to all members of the United Nations for comment, and the Secretary-General also proposes to establish a standing Preparatory Committee as well as to convene in certain regions informal meetings of experts. The Economic and Social Council is also being requested to establish a small temporary Consultative Committee representing about six member Governments.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Tuesday, April 20

ROYAL SOCIETY OF ARTS, DOMINIONS AND COLONIES SECTION (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. A. J. Wakefield: "The New East African Ground Nuts Scheme".

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (in the Chemistry Department, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Dr. W. G. C. Forsyth: "Carbohydrate Metabolism in Soil".*

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Colonel D. H. Gordon: "The Prehistoric Cultures of the Zhob and the Indo-Iranian Connexion".

INSTITUTE OF PHYSICS, ELECTRONICS GROUP (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. C. J. Milner: "Long-Wave Infra-Red Detectors".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. E. A. G. Johnson: "Flooding in the Fens and Remedial Measures Taken".

MANCHESTER GEOGRAPHICAL SOCIETY (in the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Mr. L. Brooks: "Geography in Education and Citizenship".

OIL AND COLOUR CHEMISTS' ASSOCIATION (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. K. McTaggart: "Esters of Titanium".*

ROYAL PHOTOGRAPHIC SOCIETY, SCIENTIFIC AND TECHNICAL GROUP (at 16 Prince's Gate, London, S.W.7), at 7 p.m.—Symposium on "Modern Techniques in Stereoscopy".

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7 p.m.—Mr. F. Turner: "Some Applications of the Supersonic Frequency Detector in Steelworks Inspection".

SOCIETY OF DYERS AND COLOURISTS, SCOTTISH SECTION (at St. Enoch Hotel, Glasgow), at 7 p.m.—Mr. G. H. Lister: "An Investigation into the Practical Aspects of the Absorption of Acid and Chrome Dyes by Wool".

BRITISH POLISH SOCIETY (at the Polish Institute, 81 Portland Place, London, W.1), at 8 p.m.—Prof. S. Loria: "The Organisation of Scientific and Cultural Life in Wroclaw".*

Wednesday, April 21

TEXTILE INSTITUTE (in the Council Chamber, Town Hall, Macclesfield), at 12 noon.—Annual General Meeting; at 2.30 p.m.—Mr. Allan Walton: "Art in relation to the Textile Industry" (Mather Lecture).

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1), at 2.30 p.m.—Dr. D. T. A. Townend: "Recent Developments in Combustion".*

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Robert Robinson, P.R.S.: "The Structural Relationships of some Plant Products" (Trueman Wood Lecture).

ROYAL INSTITUTE OF CHEMISTRY, LONDON AND SOUTH-EASTERN COUNTIES SECTION (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 4 p.m.—Symposium on "Laboratory Layout and Construction".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Dr. H. G. Booker: "Some Problems of Radio-Meteorology" (Symons Memorial Lecture).

ROYAL MICROSCOPICAL SOCIETY (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. E. S. Horning: "Researches on Cosmic Radiations at the High Alpine Scientific Station, Jungfraujoch"; Dr. E. P. George: "Physical Properties of Cosmic Radiation".

British Institution of Radio Engineers, Scottish Section (at the Institution of Engineers and Shipbuilders in Scotland, Elmbank Crescent, Glasgow), at 6.45 p.m.—Mr. J. B. Birks: "The Physical Applications of Microwaves".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "The Publication and Classification of Scientific Knowledge" (Speakers: Sir David Chadwick, Prof. J. D. Bernal, F.R.S., Dr. Alexander King and Dr. H. T. J. Ellingham).

Thursday, April 22

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. A. N. Drury, F.R.S.: "The Lister Institute of Preventive Medicine".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. B. Barnes: "White Flowers in *Ranunculus Flammula* Linn."; Prof. W. E. Le Gros Clark, F.R.S.: "A Review of the African Fossil Primates discovered during the Year 1947".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. J. G. van der Corput: "Properties of Rationality in Geometry".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. B. H. C. Matthews, F.R.S.: "The Nervous System as an Electrical Instrument" (Thirty-ninth Kelvin Lecture).

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Mr. H. King: "Curare Alkaloids—Constitution of *dextro* tubocurarine Chloride and its Botanical Origin"; Mr. P. Oxley, Mr. M. W. Partridge, Mr. D. A. Peak, Mr. T. D. Robson and Mr. W. F. Short: "New Methods for the Preparation of Amidines".

Friday, April 23

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion on "Solar Radio Noise".

Chemical Society, Newcastle and Durham Section (at King's College, Newcastle-upon-Tyne), at 5 p.m.—Prof. Linus C. Pauling: "The Valence of Metals and the Structure of Intermetallic Compounds" (Bedson Club Lecture).

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Newcastle-upon-Tyne), at 6.15 p.m.—Prof. A. F. Burstall: "The Work of the Engineering Department in a University".

Royal Statistical Society, Industrial Applications Section (at the Mining and Technical College, Crumlin, Mon.), at 6.30 p.m.—Dr. B. P. Dudding and Mr. W. J. Jennett: "Applied Statistics and Industrial Efficiency".

Saturday, April 24

Institution of Chemical Engineers, North-Western Branch (in the Reynolds Hall, College of Technology, Manchester), at 3 p.m.—Mr. S. H. Wilkes: "Dust Explosions in Factories".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Responsible Lecturer in Electrical Engineering—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (April 24).

Lecturer or Assistant Lecturer in the Department of Physics—The Registrar, The University, Sheffield (April 24).

Assistant Lecturer in Physics—The Principal, Municipal College of Technology, Manchester (April 26).

Professional Officer (Plankton Research), Division of Fisheries, Department of Commerce and Industries, Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, London, W.C.2 (April 30).

Lectureships and Senior Lectureships in Physics—The Secretary of University Court, The University, Glasgow (April 30).

Museums Assistants in the Victoria and Albert and Science Museums—The Museum Superintendent, Science Museum, or Victoria and Albert Museum, South Kensington, London, S.W.7 (May 1).

Lecturer or Assistant Lecturer in the Department of Civil Engineering—The Registrar, The University, Sheffield (May 1).

Registrar, and a Librarian, of University College, Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (May 1).

Technician (male) in the Pathological Department of the West Midland Forensic Science Laboratory, Birmingham—The Establishment Officer, Home Office, Room 297, Whitehall, London, S.W.1 (May 10).

Chair of Bacteriology at St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 12).

Chair of Physiology at London Hospital Medical College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 13).

Senior Assistant in the Academic Department of the Headquarters Administrative Staff—The Principal, University of London, Senate House, London, W.C.1 (May 15).

Professor in Civil Engineering at Ceylon Technical College—The Ceylon Government Representative, 28 Cockspur Street, London, S.W.1 (May 15).

Assistant Lecturer in the Department of Physics—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (May 20).

Demonstrator in the Department of Geology—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (May 21).

Assistant Lecturer in the Department of Zoology and Comparative Anatomy—The Registrar, University College of South Wales, Cathays Park, Cardiff (May 31).

Chair of Statistics at the London School of Economics and Political Science—The Academic Registrar, University of London, Senate House, W.C.1 (May 31).

Associate Professor of Anatomy (Sub-Department of Human Embryology and Histology) at the University of Queensland, Brisbane—The Agent-General for Queensland, 409 Strand, London, W.C.2, or the Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Brisbane, May 31).

Professor of Physiology, and a Professor of Anatomy, in the University College of the West Indies—The Secretary, Special Committee of the Senate on Higher Education in the Colonies, University of London, Senate House, London, W.C.1 (June 1).

Lecturer in Personnel Practice in the Department of Social Studies, University of Melbourne—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Melbourne, June 30).

Nuffield Fellowships for Experimental and Theoretical Research in Nuclear Physics—Professor of Natural Philosophy, The University, Glasgow, W.2 (June 30).

Senior Lecturer in Botany at Victoria University, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Wellington, June 30).

Fisheries Officers in Malaya—The Director of Recruitment (Colonial Service), 15 Victoria Street, London, S.W.1.

Design Engineers and Planning Engineers in the Department of Atomic Energy (Production)—The Staff Section, Ministry of Supply, Department of Atomic Energy, Risley, Warrington, Lancs.

Lecturer in Biology—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11.

Scientific and Technical Liaison Officer of the International Wool Secretariat for its North American Section, New York—The Secretary, International Wool Secretariat, 18 Regent Street, London, W.1.

Lecturer in Radio Engineering—The Clerk, Northern Polytechnic, Holloway, London, N.7.

Physical Chemist or Physicist to undertake fundamental work on metal finishing problems, including electro-deposition and electro-polishing—The Secretary, British Non-Ferrous Metals Research Association, 81–91 Euston Street, London, N.W.1.

RESPONSIBILITY IN NATIONALIZED INDUSTRIES

ALTHOUGH, as Mr. Wilfred Roberts did well to remind the House of Commons in the debate on nationalized industries on March 3, the public corporation is no new feature of the social and political life of Great Britain, public concern about the efficiency and accountability of such bodies has steadily grown with the execution of the Government's programme of nationalization. The debate on March 3, which was concerned mainly with the extent to which ministers could be held responsible and questioned in Parliament concerning the activities of such bodies, followed up an earlier debate in the House of Lords on December 2 on the problems of nationalized industry. Both Mr. H. R. G. Greaves in his recent book "The Civil Service in the Changing State", and Sir John Anderson in his Romanes Lecture on "The Machinery of Government" have considered some of the fundamental problems involved in this newer type of government organisation, and there have already been published at least two critical full-length appreciations of British experience in this field—notably the study of "Public Enterprise" edited by Dr. W. A. Robson in 1937, and Mr. T. H. O'Brien's book "British Experiments in Public Ownership and Control" of the same year.

The essential problems were, in fact, well displayed fully ten years ago, but neither debate in Parliament suggests that anything like full use has been made of that experience in determining the structure of the industries already nationalized. The Lord President of the Council has on several occasions admitted the importance of proceeding cautiously and not committing ourselves to any one form or type of organisation that would hinder changes which experience might indicate as desirable. He emphasized this point particularly in an address read before the Institute of Public Administration last autumn, and, both in that address and in his reply in the House of Commons debate on March 3, he showed that he is fully aware of the importance of taking account, not merely of the questions of efficiency, accountability and responsibility, but also of ensuring enterprise and of solving the problems of economic and industrial democracy involved in the association of all classes of workers, scientific and technical as well as operatives, in the conduct of the undertaking.

None the less, Mr. Morrison rejected Capt. Crookshank's very moderate suggestion for either informal discussions between representative members of the House or for a Select Committee to investigate and report on the best way of dealing with the specific aspect of ministerial responsibility and the limits of Parliamentary questions. The distinction between administration and management was clearly grasped on all sides of the House, and it was evident that there was a general realization of the importance of the Parliamentary question, the dangers of such procedure if not used with restraint, and the vital importance of the fullest possible information being available for Parliament and the general public. Efficiency, as Mr. Bowles rightly said, would be promoted only by Parliamentary vigilance and interest, and the essential problem is to secure the appropriate balance which will ensure the continual review of institutions and yet not hamper day-to-day management or repress initiative and enterprise.

One of the many dangers, as Mr. Molson observed, is that nationalized industry may be unwilling to move with the times or to admit that mistakes have been made; and on this point he suggested that the annual reports to be presented to Parliament should be examined by a Select Committee analogous to the Public Accounts Committee and assisted by a special permanent staff. A somewhat similar suggestion for an efficiency audit was made by Mr. Diamond; but both these constructive suggestions were dismissed by Mr. Morrison without any alternative proposal being made.

Sir John Anderson's part in the debate was limited to the elaboration of one only of the principles he had emphasized in his Romanes Lecture and earlier, before the Institute of Public Administration, as essential in determining the constitution of the authority to which a particular public task is to be entrusted and the relation of that authority to Ministers and to Parliament. Parliament, he insisted, must have adequate opportunity for inquiry, debate and public judgment; but he addressed himself more particularly to the question of the extent of ministerial control and the limits within which a Minister could be questioned in Parliament. Sir John appeared to suggest that, without interfering in day-to-day matters, a Minister should be willing to deal with questions on matters which might not strictly fall within his responsibility where the supply of information was obviously in the public interest.

The importance of that point was scarcely brought out sufficiently in either House, and Sir John himself did not refer to his own earlier comment that, where an annual report was laid before Parliament under statutory requirement, the report should be debatable. That procedure would go far, if properly implemented, to provide the opportunity for constructive criticism both inside and outside Parliament, and to ensure that there was at least an attempt to secure that, under changing conditions, public corporations could be relied upon to act with vigour, to show initiative and enterprise and to accept such risks as are normally taken by private enterprise. If we must rely on the vigilance of Parliament and the alertness of public opinion to avoid inertness, inefficiency or undue public suspicion, adequate information must be available, and whatever other means are provided, the annual report appears to be one invaluable, if not indispensable, means.

Much experience has clearly to be gained before Parliament can be satisfied that a reliable technique has been evolved, and the recent debates indicated doubts on all sides as to whether we are not being asked to move too quickly. Moreover, as Lord Lindsay pointed out, there is already a large body of common knowledge which should be used to the full both in determining the structure of nationalized industry and in its operation, and it should not be forgotten how powerful an instrument for efficiency local patriotism can be. Conversely, wise decentralization can make a vital contribution not merely to the efficiency of the nationalized industries but also to the health of local government; and doubts may well be entertained as to whether the present organisation, for example, under the Transport Commission, sufficiently meets such criticism or even those of administrative theory.

The two things that stand out most clearly are, first, the necessity for self-restraint in the attitude of Parliament to the public corporations, and secondly, the need for self-restraint on the part of the Government in extending the sphere of nationalized industry before sufficient evidence is acquired that those already nationalized are working sufficiently well to encourage further steps in that direction. The most imperative need is, in fact, that the question should be taken out of the arena of party politics and examined objectively on a scientific plane. The additional and independent scrutiny of the work of nationalized industries demands information beyond that available in published reports and accounts, and if a proper public judgment of their efficiency is to be possible the boards must come into the open. Lord Knollys, for example, suggested that the chairman and other appropriate officers should be required to appear each year before the Select Committee on Estimates and the Public Accounts Committee; but Mr. Diamond, in making his own proposal, gave as one reason the opinion that such scrutiny lies, at least in part, outside the terms of reference of these two Committees. Whatever method may be adopted, however, the boards should anticipate questions by a generous disclosure of information about their plans and activities. If Parliament is to be expected to act with restraint and confine questions to matters for which Ministers are genuinely responsible, information of other kinds must be readily accessible from the corporations. The corporations must not display the resentment which has sometimes been shown, for example, by the governing body of the British Broadcasting Corporation, as a result of requests for public information; and enough should be made known as a matter of course for their progress and difficulties to be assessed accurately and promptly by outside and impartial observers. The boards are public servants and have no need of the reticence of private business in matters of finance; but they are not Civil servants, and they have a right and a duty to answer public criticism as vigorously and as independently as it is made.

That there is room for clear thinking and impartial study of the whole question is obvious from the recent debates, and it is by no means certain that the Government yet appreciates how, until the appropriate structure has been determined, the change from private to public ownership may increase the difficulties of good technical and economic management. There can be no doubt that in time independent investigation, and possibly studies by the British Institute of Management and like bodies or by the universities, as Prof. K. C. Wheare has suggested, may throw much light on the appropriate means of securing accountability and, equally important, public support and understanding of the work of such national boards.

What must be recognized is that, if we are, as the Lord President of the Council admitted, developing a field as yet comparatively unexplored, it is the scientific method that can be our best guide. There must be dispassionate and objective inquiry, self-restraint, and a rigorous refusal to let either sectional or private interest or party dogma interfere with the determination of the appropriate instruments by which to secure that the change from private to public ownership is marked by enterprise, initiative, and the rigorous service of efficiency and of the welfare of the nation. In particular, the question of accountability and of Parliamentary question and control must not be allowed to obscure those equally important issues, to which Dr. W. A. Robson has directed attention, namely, the necessity and extent of centralized control, the relation between size and efficiency in these nationalized undertakings and the means by which we are to measure the efficiency of a public service. Even in private enterprise, too narrow a conception of efficiency may be unsound; in public enterprise, to think of it in rigid financial, mechanical or even economic terms, may be disastrous. Yet when we leave these spheres and enter that of social accountancy, we may well find ourselves without reliable criteria or yardsticks. The devising and application of such yardsticks is one of the outstanding challenges for the student of social and economic science.

Questions of staffing cannot be entirely divorced from these questions of public responsibility, general and social efficiency and independence of pressure from sectional or private interests. Staff possessing the requisite qualities of initiative and enterprise, integrity, judgment and administrative ability will only become available when the service of the corporations is manifestly seen to encourage their exercise and to afford them ample scope as well as commensurate rewards.

INDUCTION OF TUMOURS BY CHEMICAL COMPOUNDS

Radiophysiologie expérimentale, cancer et hormones. 6: Etude de la cancérisation par les substances chimiques exogènes

Par Antoine Lacassagne. (Actualités scientifiques et industrielles, 1026.) Pp. 150. (Paris: Hermann et Cie., 1947.) n.p.

IN the preceding monograph in this series, Prof. A. Lacassagne discussed the chemistry of experimental carcinogenesis. The present work deals with the biological aspect of the subject. The pathology of chemical carcinogenesis, including the transport of carcinogenic substances in the body, the effect of carcinogens on cells, and the action of substances which modify the carcinogenic process, are discussed.

The outstanding known facts about the transport of carcinogenic substances are that they are changed chemically and excreted as derivatives in bile. The details of the chemical transformations which carcinogens undergo are still uncertain, and it is not known with certainty whether chemical change of the carcinogenic substances in the tissues is necessary for them to exert their carcinogenic action. If 1:2:5:6-dibenzanthracene or 3:4-benzpyrene is injected into animals, the greater part of the material is excreted rapidly; but a small fraction appears to remain at the site of injection for many months. The slow nature of the carcinogenic process would suggest that it is the small amount of fixed material which is the cause of the carcinogenesis. The observation of R. R. Bensley and N. C. Hoer (1934) that injected benzpyrene becomes concentrated in the mitochondria of cells is perhaps of importance in the process.

The specific changes which carcinogens are known to produce, apart from the induction of cancer and inhibition of growth, seem rather unimportant. More is known of the factors capable of modifying carcinogenesis. The process of carcinogenesis can be markedly affected by diet. Thus the carcinogenic action of tar or hydrocarbons on the skin is greater in animals maintained on diets with high fat content, and the effect of azo compounds in producing hepatomas is reduced by giving animals diets with high protein and vitamin B content. The carcinogenic action of hydrocarbons in subcutaneous tissue is influenced to some extent by the nature of the solvent used to introduce the carcinogen. These effects do not help much, as yet, in the understanding of the underlying changes of carcinogenesis. A vast amount of work carried out on the modifying action of physical agents on carcinogenesis is reviewed by Prof. Lacassagne, with the conclusion that it is difficult to say whether physical and chemical carcinogenic agents act synergistically, independently or in antagonism.

Prof. Lacassagne describes the growth-inhibitory action of carcinogenic substances discovered by Prof. A. Haddow, and discusses the antagonistic effect of weak carcinogenic compounds on potent carcinogens, which has been largely investigated in the Paris laboratories. In a typical experiment showing the antagonism, carried out by Prof. A. Lacassagne and his colleagues, one group of mice was treated with methylcholanthrene, a potent carcinogen, while a second group was similarly treated with a mixture of methylcholanthrene and a weak carcinogen, 1:2:5:6-dibenzfluorene. Tumours appeared later and life was prolonged in the second group, so that the weak carcinogen appeared to have an anticarcinogenic action, possibly by a blocking or competing mechanism. Even the growth-inhibiting action of 1:2:5:6-dibenzanthracene is reduced by addition of the feebly carcinogenic 1:2:5:6-dibenzacridine. This last result indicates the close correspondence which exists between growth inhibition and carcinogenesis. The action of carcinogenic hydrocarbons is neutralized by agents other than feeble carcinogens, including vesicants and substances which can combine with sulphydryl groups of amino-acids.

Theoretical chemistry has given to students of carcinogenesis a unifying hypothesis, which appears to be possibly more satisfactory than experimental work alone had been able to supply. The development of the theory by O. Schmidt, N. Swartholm and the French workers, R. Daudel, A. Pullman and B. Pullman, is described. Calculations of the distribution of free electrons in many series of polycyclic compounds indicate that there is often particularly high density of electrons about certain bonds between carbon atoms. In the polycyclic carcinogenic compounds, the charge or density of electrons is above a certain limiting level, and high carcinogenic power is associated with high electron density or charge. This hypothesis, if further substantiated, should lead to better understanding of the underlying mechanism of the actions of carcinogenic substances.

Prof. Lacassagne's last chapter contains descriptions of many different substances which have produced tumours in animals. These include carbon tetrachloride, hydrochloric acid and sodium hydroxide in mice, glucose and sodium chloride in rats, and zinc chloride in cockerels. This list of odd carcinogenic agents would give the impression that carcinogenesis is not a specific property associated with definite chemical structures. Most of the work carried out in the field, however, points to definite correlation between structure and carcinogenic action, although the basis of the relationship is as yet unknown. Any comprehensive theory of carcinogenesis must also account for the action of the ionizing radiations, as well as the hundreds of known carcinogenic substances, the hormones and possibly the viruses.

In these monographs, Prof. Lacassagne has stated the main known facts of the subject and so revealed the gaps in our knowledge, and also the way to better understanding of this fascinating corner of science which is so important to mankind.

E. BOYLAND

DOGON PERSONALITY

Les Âmes des Dogons

Par G. Dieterlen. Pp. viii+268+15 plates. 100.70 francs.

Les Devises des Dogons

Par Solange de Ganay. Pp. viii+194+9 plates. 100.70 francs.

(Université de Paris: Travaux et mémoires de l'Institut d'Ethnologie, Tomes 40 and 41.) (Paris: Institut d'Ethnologie, 1941.)

THE social and religious institutions of the Dogon, a cliff-dwelling Negro tribe of Mendi origin who occupy the Bandiagara escarpment of the French Sudan, have formed the subject of extensive study by members of the Institute d'Ethnologie of the University of Paris under the leadership of Prof. M. Griaule. Their eight years of field-work, perhaps the most extensive and sustained yet undertaken in Negro Africa, is now beginning to bear fruit; "Jeux Dogons" and "Masques Dogons", both by Prof. Griaule, appeared in 1938; "Organisation social des Dogons" by Mme. de Paulme-Schaeffner in 1940, and these were followed in 1941 by the two monographs now reviewed, which only recently reached Great Britain.

The first, by Mme. Germaine Dieterlen, is on the Dogon conception of the soul, and is a clear and lucid exposition of a very complicated subject. A Dogon, in addition to his shadow (*kikinu bumone*), has two conceptions to which the term 'soul' could be applied: his *kikinu say*, an oversoul or true soul and a kind of super ego, and his *nyama*, a life-force or under soul, equivalent to his ego or personality. At death the *kikinu say* goes to join the ranks of immortal spirits and ultimately becomes an ancestral spirit, while the *nyama* is transmitted to his descendants. Thus the object of Dogon ancestor worship is to maintain the goodwill of the ancestral *kikinu say* and to sustain the power of his *nyama* among his descendants. For the *nyama* is not reincarnated intact in a particular descendant. A man's *nyama* is a complex affair derived from a number of different sources; part of it comes from the father who begat him, part from a particular ancestor transmitted to him while still in the womb, and part again from the clan and lineage ancestors imparted to him after birth at his naming ceremony.

The second work, by Mme. Solange de Ganay, is a study of the titular forms of address (*tige*) found among the Dogon. This custom of using special terms of address towards a person, or in many cases towards an animal or natural object, is characteristic of the Mandingo, Mossi, Joloff, Susu and other peoples of the French Colonies of Sudan and Senegal; but this is the first specialized study that has been made of it. A Dogon can be addressed by no less than twelve different kinds of *tige* indicating respectively his tribe, village, family and other social groupings, his occupation, his personal idiosyncrasies and even particular parts of his body. The particular *tige* used will show how well known he is to the speaker, and the degree of familiarity that exists between them. The author concludes that these *tige* are no mere empty titles or honourable names recording a particular or a memorable feature, but contain enduring and supernatural qualities which have been transmitted to the bearer from other individuals or groups or supernatural beings, qualities which he bears during his life-time and then transmits to his descendants. As such they are analogous to the complex of *nyama* which compose his personality. To address a person by one of his *tige* is not merely a form of politeness but also an efficacious formula for placing oneself in accord with his personality.

Of the 250 pages of Mme. Dieterlen's monograph fifty are taken up with details of the mythology connected with the foundations of the various component villages of the Dogon tribe. This could well have been relegated to an appendix or omitted altogether, as it has no bearing upon her subject. Had she given instead an outline of Dogon social or economic structure, some background against which this study of their religious beliefs could be set, she would have left the reader with a more adequate and complete impression of Dogon personality. As it is, her study, like the shorter one by Mme. de Ganay, remains an expert piece of dissection of a part of Dogon ritual and belief, but one necessitating a perusal of the three previous works for its proper appreciation.

G. I. JONES

PERSONALITY

The Cultural Background of Personality

By Prof. Ralph Linton. (International Library of Sociology and Social Reconstruction.) Pp. xii + 102. (London: Kegan Paul and Co., Ltd., 1947.) 10*s*. 6*d*. net.

THE late C. P. Scott and H. W. Nevinson were once exchanging stories which had never been printed; Nevinson complained ruefully that when he was sent to report the 'Black and Tans' in Ireland, he was shot at by both sides. Prof. Linton takes a greater risk; in his brave attempt to cross-fertilize several different studies, he may be attacked from three sides. Obviously he cannot be ignored.

During man's long effort to understand himself, there have recently arisen the disciplines of psychology, sociology and anthropology. In Britain there are now few universities without a department of psychology, and few with departments of anthropology or sociology. So perhaps readers in Great Britain will be less touchy about threatened vested interests, but more aware of sins of omission.

Prof. Linton discusses the interrelation of the individual, society and culture, clearly, fairly, with masterly compression, in ninety-nine pages. The present reviewer wishes that reference to the work of psychologists had been less allusive, perhaps even less complimentary. But Prof. Linton writes, "most . . . of the information which we have on personality in non-European societies has been collected by anthropologists who had only a nodding acquaintance with psychology". Characteristically he includes himself in this category.

The author tackles the difficulty presented by the lack of a consistent terminology shared by all three sciences, basing his definitions upon those meanings about which there seems to be general agreement, and ignoring minority usages. As a result, he discusses very successfully the relation of the individual to culture and to society. He deprecates the practice of speaking of societies as if they have needs of their own, as distinct from those of the individuals composing them. His careful definitions of culture may build a bridge across the present gulf between psychologically minded sociologists and 'culturologists'.

There is an excellent study of personality and of attempts to find 'basic personality types' for a society. The author cites many more concrete examples than is usual in a book of this type. Its prevailing mood is enthusiasm, and its sentences are not written with the sole aim of rendering them criticproof. The dedication is "To the students whose questions may induce their professors to read this book". The effects upon both will be excellent.

T. H. Pear

PALÆOBOTANY

An Introduction to Paleobotany

By Prof. Chester A. Arnold. (McGraw-Hill Publicaions in the Botanical Sciences.) Pp. xi+433. New York and London: McGraw-Hill Book Co., nc., 1947.) 27*s.* 6*d.*

THE author of this book is one who has made valuable additions to our knowledge of American ossil plants, especially those of the Devonian period. Here he has produced a very comprehensive treatment of the whole subject, and deals with the history f the plant world from the earliest periods in which we find evidence of the existence of plant-life down to the present day. He discusses the bearing of the vidence furnished by fossil plants on past climates, istribution of floras over the earth's surface and Wegener's theory: there is an excellent chapter on ossilization. Something more might have been added on the methods used in palæobotanical investiations, for they furnish a very clear idea of the physical nature of fossil plants. His deliberate election of American examples makes the book of reater value to the American student than to those ho are not acquainted with details of American eography and geology.

There are many illustrations which have not therto appeared in text-books, and for the European palæobotanist it gives an excellent idea of American palæobotanical material. The illustrations are scarcely adequate for the amount of text, or for a book which claims to be an introduction. The treatment of the groups is rather uneven: in the chapter on the ancient Lycopods there are no figures illustrating the structure of a 'cone', a Stigmarian base or a reconstruction of a complete arborescent Lycopod, although the considerable mass of evidence available would justify one. The Calamites, though less important constituents of carboniferous vegetation, have in comparison adequate illustration. In the later chapters there are twenty-one illustrations of dicotyledonous leaves, which seem more than necessary. The space utilized for two-thirds of them might have been more effectively used in the illustration of other chapters.

The book more nearly approaches a text-book than an introduction to the subject. The very large number of types, many merely introduced by name or with brief descriptions, will make the book rather heavy going for anyone who has not a fairly wide knowledge of the subject already. It is a useful addition to the library of those engaged in palæobotanical research; but it is doubtful whether a university undergraduate would find it of much assistance except for occasional reference.

John Walton

LOGICAL REALISM

A Preface to Logic

By Morris R. Cohen. Pp. xix+202. (London: George Routledge and Sons, Ltd., 1946.) 8*s.* 6*d.* net.

The Revival of Realism: Critical Studies in Contemporary Philosophy

By James Feibleman. Pp. vii+333. (Chapel Hill, N.C.: University of North Carolina Press; London: Oxford University Press, 1946.) 22*s.* net.

THESE two books both advocate logical realism, as opposed to the conceptualism or nominalism which has been fashionable in Western thought since the fourteenth century. Undoubtedly universals are concepts, but concepts are not generic images, as Prof. Cohen points out; nor are universals merely concepts if they play their parts successfully. Undoubtedly names are special kinds of universals, but to say that universals are merely names is to make knowledge illusory.

The greater part of Prof. Feibleman's book is devoted to criticism of recent thinkers. C. S. Pierce, as a realist, is approved; so is Whitehead, with reservations. Dewey, Lovejoy and Russell are dealt with more severely; especially Russell, for deserting his first love and for his prolonged, though half-hearted, flirtation with nominalism. There is an interesting section on history and the views of Toynbee. Prof. Feibleman's methods are Procrustean. If a thinker is not a proper (Aristotelian ?) realist, he is either an idealist, the exaggerated Platonic kind of realist, or a nominalist; and nominalists are either materialists or subjective idealists. This is hard on thinkers who do not fit the labels, like Kant. These, if not actually engaged in crime, are convicted of 'loitering with intent'.

Prof. Cohen's book, though smaller, carries more weight than the other, because he is constructive, never extreme, always balanced in judgment. He discusses topics that lie on the borders of logic; the relation of form and content in assertion and inference; the nature of symbols, meaning, concepts, fictions and probability, and the logic of ethical judgments.

A reading of both books raises the old puzzle of what logic really is. Both writers repudiate the psychological interpretation. Prof. Feibleman says that logic is the general science of system or of types of order, and that pure mathematics are branches of logic. But surely the value of the mathematical sciences comes from dealing with specific types of order which are definitely of one sort and not another sort; as, for example, arithmetic deals with what has certain sorts of serial order and not with anything else. Can there be an entirely general science of order or system as such? Would it not be like that science of pure being, which, in spite of Aristotle and the Schoolmen, has never yet appeared? Aristotle's logic may be, as Prof. Feibleman says, a calculus of substance and a rather inferior business, while recent symbolic logic is a calculus of relation and far superior. Even so, they remain distinct specific sciences, and where is the generic science? Prof. Cohen in his preliminary statements says that logic is the formal element within any science, and does not appear to commit himself further. There seems to be no objection to this view, and perhaps this is all that needs to be said.

A. D. RITCHIE

RECLAMATION DISEASE IN AGRICULTURE

Koper als onmisbaar element voor plant en dier

Door W. J. Melchers en H. J. Gerritsen. Pp. 56+25 plates. (Wageningen: Gebr. Zomer en Keuning, 1944.) 1.90 fl.

"RECLAMATION disease", due to a faulty copper balance in the soil, is of considerable importance in Holland, and much research has been done on it. Melchers and Gerritsen have set out the more recent results dealing with the control of the disease, and an English summary renders the book accessible to a wider circle of readers.

Reclamation disease was originally thought to occur only on peaty-humus soils, but it is now known that it may be associated with various other types, such as pure sandy and also peat bog soils. Apparently soil containing black pitchy heather humus and/or bleached sand is the most susceptible to the disease. Early work assumed that reclamation disease was the result of definite copper deficiency; it is now realized that copper may be present in the soil but fixed in such a form as to make it difficult for the plant to absorb and utilize it.

The susceptibility of crops to reclamation disease varies with the species, cereals and leguminous plants suffering most. The symptoms vary, but usually the reproductive phase is more affected than the vegetative, though white clover offers a good example of profuse flowering and feeble leaf formation in sick plants. The chief agricultural crops are listed according to their liability to reclamation disease, with the special symptoms in each case. On grassland the botanical composition of the herbage may indicate copper deficiency, and the colour is usually strikingly dull and yellow. The better-quality grasses disappear, and the inferior varieties predominate. Cattle grazing on such grassland exhibit symptoms of disease which vary with the type of soil, and these have been proved to be associated with copper deficiency.

The degree of copper deficiency in the soil is usually determined by tests with *Aspergillus niger*, a fungus which requires minimal quantities of copper for its growth and spore formation. The only remedial measure at first used was the application of town compost; but this was limited to areas where transport costs were not prohibitive. Stable manure proved inefficient in action, but good results have been obtained by covering the deficient soils with a layer of sand about 10 cm. thick.

The application of sulphate of copper at the rate of 50–100 kgm. per hectare has proved successful in preventing reclamation disease on ploughed land. On grassland direct application is of little use, and it is necessary to plough up and cultivate the land with other crops for about two years until the lime and copper contents have been adjusted, after which grass can again be sown with more hope of success. The beneficial effect of the copper sulphate will last for several years, but for some crops, as wheat, that are more susceptible to reclamation disease, it may be necessary to give a second application sooner than with others. Finely ground slags containing a low percentage of copper produced by copper foundries are as efficient as copper sulphate, and they may be of special advantage owing to the better distribution obtained by the larger quantities necessary to supply the requisite amount of copper. Such slags are also a useful source of supply of various minor or trace elements. It may well be that continued experiments along these practical lines will do much to improve crop production in areas where reclamation disease is liable to occur.

TEMPERATURE MEASUREMENT

Methods of Measuring Temperature

By Dr. Ezer Griffiths. Third edition, revised and reset. Pp. x+223. (London: Charles Griffin and Co., Ltd., 1947.) 20*s*. net.

THE adequate control of temperature is of fundamental importance in nearly all branches of science, and there are numerous applications i industrial and technical fields. Courses of study an text-books for students of physics, chemistry, engineering and metallurgy, invariably include, in the hea section, a discussion of the methods of temperatur measurement; but, in general, the treatment is to brief and inadequate. The practical difficultie inherent in all thermal measurements are very rarel appreciated, and insufficient regard is paid to th necessity of a correct choice of instrument an method for the temperature or temperature-differenc measurement.

Those responsible for research or for the successf operation of industrial processes involving the precis measurement of temperature, therefore, have nee of a suitable book, which, while giving a gener survey of the subject, pays particular attention to th experimental basis of the methods in general us to the accurate calibration of the instruments, an which points out clearly the errors, and the means c countering such errors, to which pyrometric observ tions are liable. Dr. Ezer Griffiths, who, as a princip scientific officer in the Physics Division of the Nation Physical Laboratory, is engaged in directing researc in this particular field, and who has himself contributed much to the advances made in the subject, is undoubtedly one of the few people well qualified to write such a book. The first edition of his book on temperature measurement appeared in 1917, was quickly exhausted and for four years was unprocurable. In 1925, the second edition, a substantial improvement on the first, was published, and now, after an interval in which the second edition also has been out of print, a completely revised and re-set version has been issued. Both earlier editions were widely accepted, a clear indication that the author succeeded admirably in his task of presenting his material in a form acceptable and useful to those engaged in industry and research.

The second and third editions, superficially, appear to be little different. The chapter and sectional divisions, including their headings, are essentially the same. The illustrations and diagrams, though slightly fewer in number in the new edition, are exactly as before, and, in spite of an interval of twelve years, only minor corrections and additions have had to be made to the numerical tables. A closer examination of the text, however, reveals that the author has made a careful revision in accordance with his own practical experience, and that of others. For example, Chapter 3, on the resistance thermometer, by omitting discussion of the Smith's difference bridge, finds space for the constructional details of the standard resistance thermometers in use at the National Physical Laboratory, and in Chapter 4, on the thermocouple, brief references to thermo-elements suitable for temperature measurements of liquid steels, in gases, and of the cylinder walls of engines, have been added.

In 1927, the International Temperature Scale was provisionally adopted, and due importance is given to this scale by the reproduction, in an appendix, of the specification finally accepted. The composition of temperature-indicating points, and a table of the agreed melting-points of the elements, form two other new appendixes.

The new edition is very well produced, and the reader will find that the larger type now used makes the book easier for reference and more pleasant to use. One minor blemish is that, although the references at the ends of the several chapters have been brought up to date and arranged in chronological order, care has not always been taken to give the complete reference, or to be consistent in the form and abbreviations used. S. WEINTROUB

METEOROLOGY FOR THE PROFESSIONAL METEOROLOGIST

Meteorology

Theoretical and Applied. By Dr. E. Wendell Hewson and Richard W. Longley. Pp. xii+468. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1944.) 4.75 dollars.

THE writers of this book have been ambitious; they have attempted, within their 450 pages, 8¼ in. × 5⅜ in., to provide the physicist with an adequate text on all those parts of meteorology which are likely to be of concern to him in practising his profession in, say, one of the national meteorological services of the world. Whether they can be said to have been successful depends largely upon one's like or dislike of the plan they have adopted, which is to divide the subject somewhat arbitrarily into the two parts indicated by the title, and to make each part more or less self-contained, so that the 'practical' aspects of the subject can, if required, be read separately from the basic theory on which the applications depend. Thus, following an introductory chapter outlining the broad features of observations over the globe, Part 1 on theoretical meteorology comprises chapters on subjects of the expected kind (statics, thermodynamics, radiation, dynamics, etc.), but also one on the principles of meteorological statistics—a rather happy inclusion. Part 2 on applied meteorology deals with instruments and observations; the general circulation; vertical stability, air masses, weather systems and winds; fog, cloud, precipitation and aircraft icing; climatology; chart analysis and weather forecasting; and meteorology in relation to human activities. Rigour is claimed for the treatment in Part 1, to which the reader is referred for the derivation of results used in Part 2, which is more sparing of mathematics than Part 1.

Such a structure has no great appeal to the reviewer, for the content of much of Part 2 is as genuinely theoretical as Part 1, and the student coming to the subject for the first time is liable to get an unbalanced view. It is true that a more formal treatment can result in a lack of knowing 'what the subject is all about'; but that is readily avoided by bringing theory into relation with observation at every possible stage so as to provide the student with a coherent view of atmospheric processes. The writers of the book under review have certainly tackled very successfully the relation between theory or fundamental physical principles and observation in a number of cases, at the expense, however, of an irritating accumulation of cross-references and the loss of logical development in the exposition.

Aspects of the book which appeal to the reviewer are the treatment of instability; the nature, causes and occurrence of fog, cloud and precipitation (within the bounds of existing knowledge); and the application of climatological factors to an understanding of weather and its variations at particular places—one rather regrets, however, the limited definitions of the content of climatology. The rigour claimed for the treatment in Part 1 is not always evident; this is sometimes due to problems being incompletely specified, for example, the transfer of heat and matter by turbulence. There is a frequent insistence that a geostrophic wind field implies a stationary pressure field, but no mention of the fact that this derives from the neglect of the variation of the Coriolis parameter with latitude; on the other hand, there is frequent reference to vertical motion with north–south geostrophic flow—the relation of vertical motion and the equation of continuity to pressure change needs far more careful handling. Occasional looseness in definitions is also evident, as in confusing thermal conductivity with diffusivity and frequency with wave-number.

The book is, however, mainly workmanlike and within its structure attractive. If a second edition is called for, many blemishes can be removed, and the reviewer hopes that the writers will then reconsider their policy of omitting references from the text—a few are given in chapter bibliographies at present. He also hopes they will omit the existing diagram showing the high atmosphere to be composed of helium, unless, of course, some evidence accrues for this in the meantime. P. A. SHEPPARD

Mechanisms of Reactions at Carbon–Carbon Double Bonds

By Prof. Charles C. Price. (Polytechnic Institute of Brooklyn: Lectures on Progress in Chemistry.) Pp. viii+120. (New York and London: Interscience Publishers, Inc., 1946.) 15*s*.

THIS is the first of a proposed series of books by visiting lecturers to the Brooklyn Polytechnic Institute, who are reviewing progress in chemical topics. The treatment is not comprehensive, but stimulates interest by an able summary of many recent trends in olefinic chemistry. About half the book deals with the electronic theory of double-bond reactivity in ionic and free-radical processes; in the remainder these themes are developed with special reference to polymerization. Prof. Price writes from the point of view of an organic chemist; but is quick to perceive relevant physical evidence, and makes a number of interesting suggestions on problems of mechanism.

Particular prominence is given to electrostatic field effects of substituents, especially on π-electrons. Quantitative treatment is carried out by resolving electric dipole moments into bond moments and into separate charges. Rather a wide choice of sizes and arrangements of charges would appear possible, so that while the magnitudes of the effects are fittingly emphasized, the numerical results may well only be accepted with reserve. Descriptions would have been easier if there had been a greater readiness to admit into the vocabulary the term 'resonance', while the distinction drawn in places between this term and mesomerism will mean nothing to many chemists, to whom the words are synonymous.

The chapters on copolymerization and emulsion polymerization are especially interesting, and opportunely emphasize the fact, regretted by academic chemists, that publication of knowledge of these phenomena, though increasing, is still the exception rather than the rule. The apparently established use of the term 'condensation polymerization' for polycondensation is unfortunate.

More description might be given, in the text, of some of the reactions formulated; but the book is pleasantly printed. J. SHERIDAN

The Microscope

Its Theory and Applications. By J. H. Wredden. Pp. xxiv+296. (London: J. and A. Churchill, Ltd., 1947.) 21*s*.

The Intelligent Use of the Microscope

By C. W. Olliver. Pp. viii+182. (London: Chapman and Hall, Ltd., 1947.) 12*s*. 6*d*. net.

BOTH these books give a detailed account of the use and the optical theory of the microscope. It is unfortunate that so little training in the proper use of the instrument is given in biological courses, and the student often arrives at the research stage with little or no knowledge of its finer use, particularly in regard to lighting, screens, sub-stage focusing and the aperture of the objective. These books may then be welcomed as directing attention to the many optical problems affecting the critical use of the microscope. Both are well provided with illustrations, and particular attention is paid to the sub-stage optical equipment and the careful selection of a light source.

Chapters on photomicrography, light filters, and the polarizing microscope are given, and Mr. Wredden, who writes from the point of view of one who uses the microscope in the study of industrial and electrical problems, includes a chapter on micrometry. This book also contains tables of refractive indices of various substances, an index of visibility and a number of useful constants. The chapter on the preparation of specimens, although containing a number of useful hints to the beginner, is not very applicable to biological technique.

While Mr. Olliver goes into rather less detail, his book would be of great value to everyone engaged in microscopic work. At the same time, it may be observed that these instructions are of little use unless improvement is made in the condition of microscopes used by students in some biological departments, for many of these date from the early days of the century and are long past useful service.

Petrographic Micro-technique

A Practical Handbook for the Preparation of Thin Sections of Rocks for use with the Petrological Microscope. By A. V. Weatherhead. Pp. x+102. (London: Arthur Barron, Ltd., 1947.) 12*s*. 6*d*. net.

THE author of this little book has performed a notable feat, namely, to arrive within a reasonable distance of making a manual process comprehensible by means of the printed word. Nothing will compensate for lack of practice (and patience) in making thin petrographic sections, but much fruitless labour will be avoided by following in Mr. Weatherhead's steps. Perhaps the most interesting points are his experience with 'Norbide' (B_4C), as an abrasive of extreme hardness, and his use of complementary colours in controlling thickness in the course of preparation of specimens. To have achieved vertical and horizontal sections of eggshell is remarkable. If a blemish may be mentioned it is the use of the phrase "doubly polarized light". Maybe this is scarcely wrong, but it is not traditional, and is apt to mislead. "Between crossed nicols" (even if in these days we use calcite substitutes) seems preferable as a description. But this is a trifle: as a guide to micro-technique, this monograph is a first-class effort. F. I. G. RAWLINS

Algebra

By Dr. A. Page. Pp. vii+346. (London: University of London Press, Ltd., 1947.) 18*s*. net.

THIS book is designed to meet the requirements of students preparing for examinations of the higher school certificate, intermediate and final general degrees, as well as university scholarships. It is a thoroughly sound course enhanced by many practical applications of algebra to physics, chemistry, engineering, economics and medical science. There is also, among the thirteen chapters, a valuable one on statistics. The difficulties of the subject are skilfully surmounted in an interesting way, and the book is well provided with exercises both on the text of the several chapters, and miscellaneous in the form of revision papers, to all of which answers are supplied. Only one small point calls for comment: the chapter on determinants—the last in the book—seems to come a little too late in the course. Further, it appears to contain no applications to the solution of equations, which is rather a pity, in view of the practical importance of this aspect of the subject. Nevertheless, the book may be confidently recommended as a very useful text-book for students generally, as well as for those studying for the specified examinations.

ORGANISATION AND WORK OF THE CAVENDISH LABORATORY*

By Sir LAWRENCE BRAGG, O.B.E., F.R.S.

THE Cavendish Laboratory is faced with problems which are common to most scientific laboratories in this post-war period, and arise from the great expansion in the numbers of undergraduate and graduate students. Part of this increase is a temporary phenomenon. Men are being released from the Forces who have missed the whole or part of their undergraduate time at the university, and are returning to swell the classes. The increase in the first- and second-year students at Cambridge is perhaps not as great as it is in other universities, because the undergraduate population is limited by college accommodation; in physics these classes at present are some 50 per cent greater than they were before the War. The numbers in the final honours class, however, have almost trebled, because men returning from war-work for the most part join this class, which now has about a hundred and twenty students. It will probably remain considerably higher than its pre-war level, because the recommendations of the Barlow Report reflect the need of the nation for more scientists, and demand is creating a supply. The greatest increase of all is in the number of research students, and here the Laboratory is crowded to capacity, if not overcrowded. Although all available places are used, the number of those who apply for admission as research students is three or four times as great as the number which can be accepted each year. More than a hundred and sixty researchers are now working in the Laboratory, of whom 110 are research students working for their Ph.D. degrees —between one-fifth and one-sixth of the total number registered for research degrees in Cambridge.

This large increase implies a major change in the organisation of the Laboratory. The old days when the head of the department could be in close contact with all his research students are a matter of the past. There would appear to be a limit in organisations of all kinds to the number of men whom any one head can direct by close personal contact, this number being about six. It applies in the direction of research ~~as well~~, and devolving of responsibility is essential when numbers rise above this limit. Even before the War, numbers of researchers in the larger laboratories were approaching the 6^2 level, and now they are in the 6^3 region. In other words, the organisation of the research work involves splitting up the men into large groups under leaders, and these again into smaller groups, so that the head of the department is two removes from the researcher himself. Except in a few special cases of work in which he is particularly interested, he cannot afford to spend that two- or three-hour period every fortnight or so talking over his work with the individual, which is essential for real direction.

The major groups in the Cavendish Laboratory are nuclear, radio and low-temperature physics, crystallography, metal physics and mathematical physics, with some minor groupings. It may be interesting to give some account of the extent to which these groups are independent, and of the common ground on which they meet. The great foe of research is administrative responsibility. A nice adjustment has to be made between giving the heads of groups as much freedom as possible to make their plans for using their facilities to the best advantage, and at the same time relieving them of the more tiresome and mechanical details of administration which can be properly centralized. In our organisation each group has its own allocation of the budget for the year, and its own order-book, so that apparatus and supplies can be bought within that budget; each has its own staff of assistants and its workshop; it has its own secretary for clerical work; further, each group runs its own colloquium, where scientific papers from other laboratories are discussed and the researchers give reports of their progress. The days are past when most researches in a department were on closely related lines and a joint colloquium was possible. A colloquium in one group or another is now an almost daily event, and no individual can spare the time to go to them all. Common touch is kept up by the fortnightly meetings of the Cavendish Physical Society, where the heads of the groups give an account of the work going on in their sections, and distinguished visitors speak, and by more informal meetings of the leading researchers, such as the little club which was founded by Kapitza when he was head of the Mond Laboratory.

The administrative burden of the teaching staff has been much lightened by the appointment by the University of a secretary to the Laboratory. This officer has in his charge finance, appointments of assistant staff and rates of pay, the formal work concerned with admissions, structural alterations and upkeep of the buildings, preparation of agenda for meetings, and other matters of this kind.

A main workshop serves all sections of the Laboratory, where work requiring special tools and skills is carried out; glass-blowing is also centralized. There is also a separate central workshop where research students can use the machine tools, where the young assistants are trained, and where repairs to class-apparatus are carried out. In addition, two special centres deserve mention. It has been found convenient to have a 'special techniques' workshop where the most highly skilled and delicate work of especial kinds is carried out, and to place this workshop in charge of a member of the staff. It is largely concerned with the construction and sealing of Geiger counters, and the purification of the gases with which they are filled. Special thermionic devices are made there, and evacuated, baked and sealed. It manufactures delicate metal parts by a photographic technique, such as supports for thin-walled windows, makes special metal-to-glass or metal-to-silica joints, and has apparatus for preparing thin metal films by evaporation. The other centre, also in charge of a member of the staff, constructs and maintains electronic equipment of all kinds, such as decimal scalars and multiple coincidence circuits, or pulse and D.C. amplifiers for nuclear work. The capital value of the electronic equipment of this kind approaches five figures, and it is a saving of time and money to place it in charge of an expert.

The largest group in the Laboratory is the nuclear physics group, under Prof. O. R. Frisch and Mr. E. S. Shire, with some forty researchers. The Cambridge equipment includes the one-million and two-million volt sets in the high-tension laboratory, and a cyclotron with 37-in. pole-pieces. A five-million volt Van de Graaff generator is being built for the Laboratory by the English Electric Company, and it is hoped to get it running by the end of 1948.

---

* From a course of three lectures at the Royal Institution on March 4, 11 and 18.

The maintenance of these large and complex units introduces problems of a new scale in a physics laboratory. It creates the need for a new type of staff member, the 'technical officer'. He must be a trained physicist, in general a university graduate, but a man who has the engineer's outlook and who is interested in the construction and functioning of the apparatus rather than in the research which is done with it.

The radio group represents the continuation in the Laboratory of the work which Sir Edward Appleton started when he occupied the Jacksonian chair at Cambridge ; it is now under the direction of Mr. J. A. Ratcliffe. It has field stations as well as its section of the main Laboratory. The work on propagation is mainly concerned with the longer wave-lengths which are reflected below the *E*-layer. Another section is making measurements of the waves in the metre wave-length region coming from the sun; recording their intensity and propagation and estimating the size of the source from which they come by a method analogous to Michelson's method of measuring the angular diameter of a star.

The Mond Laboratory is now under the direction of Dr. D. Shoenberg, its former head, Dr. J. F. Allen, having been recently appointed to St. Andrews. A main interest is the properties of superconductors, in particular the penetration of magnetic fields into superconductors. It has equipment for the magnetic method of cooling. Liquid helium is at present made by Kapitza's expansion machine; but a new machine of greater capacity and more orthodox type is under construction.

In crystallography, under Dr. W. H. Taylor, the arrangement of atoms in minerals, alloys, organic compounds and proteins is being studied. The section studying proteins under Dr. M. F. Perutz and J. C. Kendrew has this year been accorded the backing of the Medical Research Council. The elucidation of the structure of such enormous and complex molecules is the most ambitious problem as yet tackled by X-ray analysis, and success would cast a flood of light on the structure of living matter.

The metal physics section, under Dr. E. Orowan, is concerned with problems of slip and plasticity, fracture, crystal growth, and metallic phenomena in general investigated by physical methods.

The Laboratory houses an electron microscope service which is used by all departments of the University. It provides hospitality for several researchers from other departments. Particularly welcome guests are the mathematical physicists, including the Plummer professor, D. R. Hartree, who have rooms in the Laboratory.

It may be of interest to assess in round figures the cost of research in the Cavendish Laboratory. The figures must be approximate, since many of the services are common to teaching and research. As an example, in the following estimate the time of the University staff is regarded as divided equally between teaching and research, and its cost apportioned accordingly. Making similar adjustments for administration, assistant staff, stores and apparatus (almost entirely research) and so forth, the total expenditure on research in the Laboratory (including the Mond) was just short of £60,000 in 1946–47, of which £10,000 came from outside sources. To this must be added a sum to represent the rental of the buildings, which does not appear in the estimates. In estimating the cost per research student, the abnormal position of nuclear research must be taken into account. Not only are the running expenses above the average, but also units such as the cyclotron represent a large outlay of capital, and special grants are made by the Department of Scientific and Industrial Research to meet needs which the University cannot finance from its own resources. Such requirements vary very greatly from year to year, and I have therefore only included a sum for nuclear research which corresponds to the expenditure per researcher in other branches of physics, and which roughly represents the contribution which the University itself makes towards the cost of the nuclear research. On this basis, the cost per research student is £400 a year. If to this is added £350 to represent the average maintenance grant of junior and senior workers, the total cost to the State of maintaining a research worker in the Cavendish Laboratory is £750 a year.

MAN'S ORGANS OF SPEECH

THE Huxley Memorial Lecture for 1947, under the auspices of the Royal Anthropological Institute, was delivered by Dr. W. L. H. Duckworth, reader emeritus in human anatomy in the University of Cambridge. The subject was "Some Complexities of Human Structure"*. The approach was frankly anatomical and was a meticulous and masterful analysis of the facts, anatomical and racial, relating to the organs of speech in man. Duckworth wasted no time on the classical definitions of anthropology ; he ignored the subdivisions of the subject and refused to be drawn into the finer distinctions of zoological anthropology, physical anthropology, social and cultural anthropology and ethnology. He kept clear of the pathological and avoided the theories of aphasia from Broca and Bastian to Henry Head. Here was the approach to the anatomical aspect as emphasized by Galen in his "Methodus Medendi" : "The magnitude of a disease is in proportion to its deviation from the healthy state ; and the extent of the deviation can be ascertained by him only who is perfectly acquainted with the healthy state". Hence the justification for the intensive study of normal structure and function in man as distinct from booksellers' notes about positive health and social medicine.

Duckworth dealt in turn with our present knowledge of the anatomy of the organs of speech, from lips, tongue, jaw, palate to the component parts of the larynx and finally the brain. To listen to so distinguished an anatomist, who is also the doyen of physical anthropologists, survey the field, much of his own ploughing and harrowing, was an intellectual feast. Rarely has a lecturer given facts and their history, as T. H. Huxley demanded, and yet exposed the gaps in our knowledge in both anatomy and physical anthropology. His survey of the work to be done provided bone and grist for many young workers. Here surely was God's plenty for the young anatomist in the laboratory and the young anthropologist in the field. The survey from Cuvier's postulate that articulate speech was the distinctive character of man to the vast modern demands of phonetics, linguistics and psychology was a criticism and yet a stimulus to the biological study of the organs of speech, emphasis being laid on the need for perfect acquaintance with the healthy normal anatomical structure.

---

* Some Complexities of Human Structure. By Dr. W. L. H. Duckworth. (Huxley Memorial Lecture for 1947.) Pp. 12. (London: Royal Anthropological Institute, 1947.) 3*s.* 6*d.*

The description of the racial variation in the muscles of the lips in Australian, Negro, Chinese and White paid due credit to the careful dissections and theories of Huber in the United States and Lightoller in Australia. The gradual change from the coarsely bundled muscles of the bulky lip of the one to the finely bundled and more differentiated muscles of the smaller lip of the White was analysed both in terms of facial expression and speech. Duckworth insisted that the variety of movements accompanying the variety of structure are skilled, and saw no reason why they might not become more skilled in the future. It is interesting to note that this work of Lightoller's, ignored by most anatomists, was seized upon by Dr. E. W. Fish[1] to modify the technique of fitting artificial teeth in the aged. Fish expanded the dentures laterally so that their position was maintained by the modiolus or hub formed by the converging muscles lateral to the angle of the mouth. The utilitarian aspects of transcendental research are ever present, whether it be the grouping of relatively minute and insignificant muscles in the face or the Hertzian waves.

That strange amateur anatomist, F. O. Ward[2], in the middle of last century described the hyoid bone as "the only instance in the human body of a strictly solitary bone . . . supported in its position by the muscles and ligaments to which it gives insertion". The embryologist, immersed solely in the intricacies of the second and third branchial cartilages which contribute to the formation of the hyoid bone, has studied the early development of this bone. The possibility of changes in the structure of the hyoid bone with age, sex and vocal disability ranging from stammering to dumbness still awaits investigation. So far back as 1866, Huxley[3] described the larynx in his famous "Lessons in Elementary Physiology" as "perhaps the most singular motor apparatus in the body". Yet, in spite of Edison's invention of the phonograph in 1877, and the spread of the gramophone and wireless broadcasting in the twentieth century, the larynx has been but little studied by the modern anatomist and physiologist. As Duckworth pointed out, the outstanding contribution of recent years has been the "Mechanism of the Larynx" by Negus[7], a book "absolutely indispensable for every physical anthropologist, and for the purpose of any research in laryngology, whether normal or pathological".

In 1833 a French surgeon, Cavasse[4], pointed out that fracture of the thyroid cartilage, a result of garrotting, never takes place in the mid-line, because the two lateral parts of the cartilage unite by the intervention of a median cartilage, perfectly conscribed, which Rambaud and Regnault[5] called the vocal cartilage. It is visible by transillumination especially in young subjects, and gives attachment to the vocal cords. It is ossified from a separate centre, contains more elastic tissue in the young than the two lateral laminæ of the thyroid cartilage and affects the production of the voice. Yet Quain[6] in 1914 was content with the statement that "in the infant the isthmus of the thyroid cartilage differs from the two laminæ in being less opaque and more flexible". All other anatomical text-books have been dumb on this complexity of human structure, particularly the more recent ones.

In the second century A.D., Galen gave a detailed description of the larynx, and for eighteen centuries he eponym 'nerve of Galen' has been employed for he constant anastomotic branch between the superior and inferior laryngeal nerves. Moreover, Galen first reported the experimental proof of the function of the recurrent laryngeal nerve of the vagus by tying or dividing the nerve and thus weakening or destroying the voice of the animal. Surely, as Benjamin Franklin said, "all our knowledge . . . has been obtained by fragments, and our future acquisitions must be made in the same manner".

This brief and inadequate description of Dr. Duckworth's Huxley Lecture provokes the remark that editorial articles in *Nature* discussing the functions of universities have failed to mention one, namely, to provide for a green old age for scholars and men of science. Little note has been taken that such provision requires an atmosphere devoted to the maintenance of mental activity, cheerful disposition, simplicity of living on one hand, and absence of business urge, desire for wealth, and all tawdry ambitions of worldly importance on the other. At a time when the universities are in danger of being monopolized by the search for smaller atoms, bigger bombs, and diabolical and destructive enzyme poisons, it is well to re-echo Montaigne's last prayer "to know how to enjoy with loyalty our life". As Tocqueville and Lecky tried to make clear, this may be the very basis of anthropology.

INTERACTION OF WATER AND POROUS MATERIALS

A GENERAL Discussion of the Faraday Society on "The Interaction of Water and Porous Materials" was held at University College, Southampton, during March 31–April 2. The four groups of papers on the programme were concerned with (*a*) fundamental, (*b*) botanical, (*c*) zoological, mainly entomological, and (*d*) industrial aspects of the penetration and movement of water in porous materials. They were well chosen to provide topics on which physical chemists, botanists, zoologists, agriculturists and those interested in fibrous materials such as textiles, wood and leather, could discuss problems common to two or more groups.

The factors governing the penetration of liquids into non-living capillary spaces, the diameter of which is greater than the range of molecular attraction, are fairly well understood. The penetration pressure, $P = 2\gamma \cos \theta/r$, where γ is surface tension, r is radius of the capillary considered as a cylinder, and θ is contact angle, determines the conditions of penetration; but the contact angle depends not only on the chemical nature of the solid and liquid, but also on the geometrical structure of the solid, and whether the liquid is advancing over a dry solid or receding from a wet one. The possible reasons for 'hysteresis of the contact angle', that is, the difference between the advancing and receding angles, received much attention; it was variously ascribed to roughness of the surface, overturning of the surface molecules, multi-molecular clusters of adsorbed water on the solid, films of air or other substances adhering to the solid before wetting, and soaking of the liquid into the solid, below the surface, on contact. Any circumstance which increases the adhesion of water to the solid necessarily decreases the contact angle; previous wetting would increase this adhesion, if any of the above mechanisms were present, except perhaps the first. Roughness certainly exaggerates hysteresis, but is perhaps less likely to be its usual cause. As Cassie showed in 1944, the contact angle on a fabric may be very large if there are regular gaps between hairs or yarns, even though the chemical proofing is one which, on a smooth surface, would give only a moderate contact angle. The feathers of ducks, the 'plastron' or air-retaining structure with which some sub-aquatic insects are provided on their outer surfaces, and leather surfaces, are peculiarly repellent to liquid water, but are freely permeable to vapour; they have this type of structure.

In pores the diameter of which is comparable with, or less than, the range of molecular attraction, such as those in zeolites, the finer pores of charcoal, and possibly also some pores in wood, transport of water takes place in the adsorbed film, that is, by surface diffusion within the range of molecular attraction. Further, solids which contain such small pores often come under severe stress when the quantity of liquid in the pores alters; when the pores fill, as in the sorption of vapours by charcoal, the solid expands; when they empty, as in the drying of wood, the strains set up may appear as severe warping, unless the drying is very carefully done. Adsorption hysteresis may be due to extremely narrow pores being wedged open beyond the range of molecular attraction on penetration of the adsorbed substance, so that they do not spontaneously close when the adsorbate is removed.

The state of the water in films adsorbed on a coal surface was discussed, and evidence presented that it is not precisely similar to bulk water, as indeed might have been foreseen. No sharp discontinuity in the volume, or dielectric constant, occurs as the temperature is decreased to − 70° C. The conclusion drawn is that the adsorbed water does not 'freeze'. It might, however, be considered at least partially frozen by the act of adsorption; the coal surface probably orients the first layer of adsorbed water molecules, subsequent adsorbed layers being more or less oriented by contact with the first oriented layer.

'Oleophobic' solid surfaces, which have a large contact angle with oil but are themselves of a hydrocarbon nature, have frequently been reported, but an explanation of their properties is difficult and even their genuine existence was challenged. If they really exist, the adhesion of such a solid surface to liquid paraffin must be substantially less than the adhesion of a liquid paraffin to itself, despite the close similarity in chemical constitution. It was tentatively suggested, in discussion, that the solid paraffin-like surfaces may have the terminal methyl groups, those most likely to be exposed at the surface, spaced apart so as to make the adhesion to liquid paraffin less than that from a liquid paraffin surface. It was also suggested that some instances of apparent oleophobic behaviour are due to the drop of oil dissolving, locally, part of the outer hydrocarbon layers on the solid, and being compressed laterally by the surface pressure of the film remaining on the rest of the surface. In such circumstances the oil drop would show a contact angle with the surface, but that could scarcely be taken as proof that the original surface had oleophobic properties.

A very lively discussion took place on how far the movement of water and dissolved substances in plants can be explained by mechanisms known to exist in non-living pores. R. D. Preston, in his introduction to the botanical section, cast doubt on the classical view that sap is pulled up a tree by tension set up at the top of long continuous columns of water, by the evaporation from the leaves: the columns may easily be broken by air, which will prevent the tension being exerted; and sap rises even if saw cuts are made so as to break every column parallel to the trunk.

In the phloem, ordinary diffusion through the bulk of the liquid (assumed stationary) in the pores appears much too slow a process to account for the speed and quantity of transport. It has been suggested that mass flow may occur, pressure differences being set up osmotically, and maintained by the synthesis of solutes with high osmotic pressure, required for assimilation by the cells, in one region, and their oxidation in another region of the plant.

Particular attention was given, in this discussion, to the possibility of accelerated diffusion along cell surfaces. Van den Honert has shown that a good spreading oil can be transported in ample quantity along a water surface, from a high surface concentration to a low, by a difference of spreading pressure in the two regions; but the not very abundant quantitative data on the rate of transport along *solid* surfaces suggest that this is very slow in comparison with the rate on liquid surfaces. Equilibrium spreading pressures on solids are no doubt considerable; and some mobility, at any rate when the adsorbed layers are held by van der Waals' forces, is usual; but generally the rate of spreading on solid surfaces does not seem nearly high enough. Bennet-Clark and Lundegårdh revived Engelmann's suggestion (1872) that electric endosmose may sometimes be a cause of rapid transport, the bio-electric potential of some tens of millivolts being a high potential gradient if exerted across a very thin membrane. Just possibly these potential differences are caused, and maintained, by differences in the redox potential in two regions. Such suggestions are rather speculative, and seem scarcely adequate to account for the frequent occurrence of accelerated diffusion and transport along cell surfaces. It still seems probable that special 'secretory' mechanisms, utilizing the energy of oxidative or other chemical processes, operate; the nature of such mechanisms is quite unknown at present. Accelerated surface diffusion, whether general or confined to certain specific physiologically important substances, may be properly termed 'secretion', since if powerful enough it could convey a substance from a low to high concentration. Can there be, on biological surfaces, a chemical 'ciliary' structure which propels molecules specifically, or non-specifically, in one direction, as visible cilia propel water *en masse* over some living surfaces?

Discussion in the zoological section was largely concerned with water-proofing. Crisp and Thorpe demonstrated that the spiracles of sub-aquatic insects are covered by a complicated set of minute hairs which exclude liquid water in a manner similar to that in which the duck's feathers keep the bird dry Many insects the normal habitat of which is a dry climate have a very thin layer of waxy material or their extreme outer surface, which greatly hinders the passage of water from the insect to the exterior if this is abraded, loss of water at once increases to a dangerous amount in fairly dry air. There seems no doubt that the cuticle of insects shows 'asymmetrical permeability', that is, moisture can pass more easily in one direction than in the other, across the cuticle. This is simply explained if the cuticle consists of two sides, one side having its permeability to water vapour decreased when in contact with a fairly high humidity, the other side being unaffected, or less affected. Such a complex membrane would pass water more easily from the less moisture-sensitive side than from the other side, because, when the higher humidity is on the side most affected by water, the permeability is decreased.

Cases of actual secretion of water into the body of an insect, from a humidity less than that in equilibrium with the interior of the insect, are not uncommon with *living* insects; one explanation which was suggested at the meeting, perhaps rather too crude to be correct, is that water is first condensed in capillaries so narrow that the meniscus on the top of the condensed column of water in the capillary is very sharply curved, so that condensation takes place below 100 per cent humidity; then the contents of the capillary tube are sucked into the insect's body from below. Very large suctions would have to be exerted.

Other subjects discussed included the behaviour of water in soils, textiles, coal and wood; also the determination of surface area by adsorption of gases, or the negative adsorption of inorganic ions in aqueous solution; and the estimation of pore size from the vapour pressure required for condensation, from the viscous resistance to flow through the porous material, or indirectly from the estimated internal surface of the solid.

The proceedings were pleasantly informal and friendly, as usual, despite the grievous loss the Society has suffered through the death of its honorary secretary, Mr. G. S. W. Marlow. Although the physico-chemical explanation of many of the phenomena which the biologists brought before the meeting remains very uncertain, and some seem to require 'biological' mechanisms much more complex than those found in non-living systems, the discussion was valuable in defining and clarifying some fundamental biological processes, as well as surveying the manner in which water interacts with several important industrial materials.

N. K. ADAM

AN EXPERIMENT IN MARINE FISH CULTIVATION

By L. H. N. COOPER and G. A. STEVEN

MANY stages of the food-cycle in the sea are much better known to-day than a quarter of a century ago. None the less, the synthesis of the scattered pieces of knowledge into a coherent whole and the assessment of the weight to be given to each has scarcely begun. An experiment in marine fish cultivation such as that of Gross, Orr, Marshall and Raymont[1] in Loch Craiglin, Argyllshire, during 1942–44, which has attempted this is therefore of outstanding importance and is worthy of a considered and vigorous criticism. The experiment suffered from many shortcomings which this group of able workers are the first to admit. The aim was set very high and the time that could be devoted to the project—mainly week-ends—under the severe stress of war conditions was inadequate. The experiment failed in its primary objective of demonstrating that marine fish cultivation can be made to pay. In the series of papers embodying the results, one senses that this failure—a failure on the heroic scale—has infected the authors with so great a feeling of disappointment that in the end they have not dared to draw from their data even those conclusions that their results would seem to justify.

One of us[2] has already stated his view that encouragement of fish growth in arms of the open sea such as the North Sea or English Channel by addition of nutrients can never be a paying concern. Indeed, in not so many years there well may be a call for means of recovering nutrients, particularly phosphorus, from the sea. None the less, he feels that the Loch Craiglin experiment shows that in selected basins and arms of the sea a satisfactory return on money expended is a definite possibility.

For the purpose of the experiments, Loch Craiglin is as unsuitable as any basin well could be; but this very unsuitability has thrown into high relief some of the adverse factors with which the marine pisciculturalist will always have to contend. The waters of the Loch were nearly always very strongly stratified. This stability was due not only to heating of the surface layer in summer but also to the presence of a chronic seal of brackish water, the salinity of which varied between 8 and $28\,{}^0/_{00}$. Even under unfertilized conditions, ventilation of the water by exchange of oxygen and carbon dioxide with the atmosphere must have been restricted. The addition of nutrients encouraged the phytoplankton further to strip the surface of carbon dioxide, the *p*H rising to more than 9. At the same time, at a depth of 3 metres in this very opaque stratified water, with Secchi disk readings averaging 2–3 metres, decomposition of the rain of organisms from above lowered the *p*H to 7·5. The corresponding partial pressures of carbon dioxide calculated from Buch's tables[3] would have been about 0·18 and 18×10^{-4} atmospheres, a range of one hundredfold. Animals and plants that can tolerate such a range of conditions are few. Healthy development of a balanced plant and animal community in a fertilized basin can occur only if vertical mixing and ventilation are adequate for the increased task. The authors seem to regard this ill-ventilation as an act of God about which nothing can be done. In Loch Craiglin this is probably so; but, for future development, the engineering problem of turn-over and ventilation is possibly the most important of all. Not only would improved turn-over revivify the bottom water and fertilize the surface water with carbon dioxide, but also it would circulate the added nutrients and iron to the upper layers where plants could re-use them immediately.

The water in Loch Craiglin had always a transparency far less than that of the open sea, Secchi disk readings averaging 2–3 metres, compared with the 10–15 metres in the English Channel; and the extinction coefficient for green light ranged from 0·5 to 14 (coastal water 0·2–0·3). This means that the range of depths well suited to active photosynthesis must have been measured in centimetres rather than metres. Much of the turbidity arose from biological activity within the Loch—activity that must be better understood if a way of dealing with it successfully is to be devised.

The problem of 'weeding' also arose in an acute form. When a field is infected with even such a persistent weed as charlock, a farmer has ways of dealing with it. If he does not, he will not succeed as a farmer for long. In Loch Craiglin, bottom-living plants such as *Enteromorpha*, *Cladophora*, *Zostera* and *Ruppia* took the first large share of the added nutrients. They were weeds and needed to be treated as such, although it is hard to see how this could have been attempted with any great hope of success.

Microflagellates were richer than normal; but no clear-cut dependence on single fertilizations, light or hydrographical factors could be detected. Their growth requirements and physiology are still too little understood.

On the bottom fauna the effect of fertilization was remarkable. By the summer of 1943, sampling and computation indicated that the population density of the bottom fauna in the whole Loch had increased by an average of about 750 per cent over the pre-fertilization value; this despite heavy feeding by the large number of introduced fishes. This high value declined, however, until, in the winter of 1944, it reached a fairly stable level about 300 per cent above the corresponding pre-fertilization winter density of 1942. This increased population density produced an increase of several hundred per cent in total dry organic weight. These increases applied not to one but to all the common species useful as food. For some unexplained reason the chief two invertebrate 'competitor' species, *Anemonia* and *Ciona*, suffered a diminution in numbers. This did not apply to gobies and sticklebacks, which multiplied and flourished to such an extent that in one day, in August, they are computed to have eaten no less than eighteen times as much food as the total population of 'economic' flatfishes.

Too much weight must not be attached to the actual figures; the important point is that they undoubtedly reveal a very large increase in the invertebrate bottom fauna of the Loch due to artificial fertilization. This probably explains, in part at least, the rather unexpected finding that flatfishes in Loch Craiglin continued to feed heavily and even to grow throughout the winter.

The growth-rates of the flatfishes were investigated by means of marking experiments. These were not very successful; the marks became entangled in bottom weed and eelgrass, or inflammation of the wound interfered with growth. There was evidence, however, that unmarked plaice made the equivalent of two years ordinary growth in one year. But most work had to be done with flounders, mainly unmarked. In one year many of these showed weight increases up to about eighteen times that of the normal increment for this species in average natural conditions.

These high growth increments in large numbers of fish were not maintained. In 1943 the flatfish population was as much as 1,000 per acre (2,500 per hectare), but during the year it was very largely wiped out by cormorants, herons and at least one otter. Nevertheless, in spite of failures such as this, these experiments have demonstrated most convincingly that by the application of fertilizers Loch Craiglin, in spite of its 'dirty' bottom and unfavourable hydrographical conditions, was rapidly converted into a feeding ground approaching the richest natural feeding ground known. Although the authors have hesitated to say so, it is reasonable to believe that, if certain salient features could be dealt with, such an enclosed loch might be made far richer in fish production than anything known in Nature. These are:

(1) *Ventilation.* The addition of fertilizers must exacerbate the unbalance of carbon dioxide and pH that always develops in stratified water—and stratification is inevitable in summer or after heavy rainfall. Natural processes of vertical mixing need to be assisted. Here the engineer must be called in to devise some pumping or other mechanism for spreading bottom water on the surface in sufficient quantity to break down the stratification. Could wind power be used to keep the cost within economic limits?

(2) *Fixed plants.* These will thrive less well in deeper water, but are always likely to take toll of added nutrients. Their control provides a problem for research. In the absence of useful fish food-animals that can be encouraged to eat them, an economic outlet must be sought for the seaweeds and eelgrass which would make it worth while to harvest them. This would also reduce their drain on the nutrients.

(3) *Nature of the bottom and fishing gear.* The muddy bottom of Loch Craiglin was in many ways an adverse factor. In particular, catching the fish was undesirably laborious and less successful than it need be. Either special catching gear, perhaps traps, is called for, or a sandy bottom is essential.

(4) *Opacity of the water.* As much as possible of the daylight penetrating into the water needs to be available for photosynthesis. In physical terms, high quantum efficiency of photosynthesis is required. Intensive production of living material in the sea leads everywhere to production of matter, possibly dead plant pigments, that seem to be resistant to breakdown. Their presence restricts absorption of light by the pigments associated with living plant cells. Much more needs to be learned about the chemical substances which bring about light absorption and scattering in 'old water' and how they could be destroyed or turned to account.

Always when discussing marine fish cultivation, it is assumed that nutrients from terrestrial stocks are to be added to the sea. Yet the very great richness of Antarctic water in nutrient salts has come about by a process of concentration within the sea. Current systems, both horizontal and vertical, are such that the loss of nutrients caused by the rain of organic matter falling towards the bottom from the photic zone south of the Antarctic convergence is more than made up by upwelling of deeper and richer water. By contrast, in the Straits of Gibraltar, the relatively rich deep water flows out from the Mediterranean over the sill and is replaced by poorer Atlantic surface water. The net result of the exchange is an impoverishment in nutrients of this great Sea, and consequent poor fisheries. Cannot something be learned from these natural events that could be applied, for example, to a large tidal sea loch with a narrow deep entrance that could be easily dammed? Let it have two sluices, one at the foot of the dam, opened to allow deep nutrient-rich water to enter on the rising tide, the other at tide level to allow surface water, stripped of nutrients, especially in summer, to escape on the falling tide. In time, a concentration of nutrients would build up (as in the Antarctic) higher than would ever be found in the adjacent open sea, and should open up great possibilities of successful fish farming. Under these conditions it would be worth while to remove unwanted fixed plants for use as field dressings.

The cost of building such a dam solely for purposes of an artificial fishery would no doubt prove prohibitive. Equally the construction of such dams to convert tidal energy into electric power has also been burked on the grounds of cost. There should be no loss of hydrostatic height involved in leading the water from the foot of the dam by way of a siphon through a turbine rather than from the incoming surface water, as would normally be done. The combination of simultaneous production of power and fish from the one investment might prove economic. This is another matter for consideration by engineers. In short, this unique experiment has provided such a mass of interesting and important facts as will stimulate academic research and practical endeavour in many parts of the world.

OBITUARIES

Prof. Alexander Ogg

For more than forty years Alexander Ogg, who died on February 23, had been by common consent the much-loved leader in his subject of physics in South Africa. A Scotsman by birth, he graduated in the University of Aberdeen under Prof. Niven and afterwards obtained his doctorate as an 1851 Exhibitioner under Nernst in Göttingen. His interest in thermodynamics arose during this period, and led to his well-known English translation of Planck's classic work on the subject. After this, he was for a time a lecturer at Aberdeen, which he left to become a master in the Royal Naval Engineering College, Devonport. In 1905 he migrated to South Africa to be the first occupant of the chair of physics and applied mathematics at Rhodes University College, Grahamstown. In so doing he became by no means the least illustrious of that band of Scottish teachers who have contributed so much to South Africa.

Ogg's new department at Rhodes College was housed in part of the old military barracks and bore the inscription "Sergeants' Mess" over its door. He set to work with great vigour and in the face of many difficulties to convert it with his own hands into a physics laboratory which would be not only the best in the country but also bear comparison with any overseas. He soon became acknowledged as an inspiring teacher and attracted to his honours courses the best brains of the College, whether they intended to become physicists or not. Year after year, in regular succession, the senior overseas scientific scholarship in the Union was won by one of Ogg's students, all of whom to-day occupy leading positions in the life of the country.

In 1917, after assisting Sir William Bragg for a time in England in military research, he moved to the University of the Witwatersrand, and in 1920 to that of Cape Town, where he remained until his retirement in 1936. When the University of Cape Town moved to Groote Schuur, he planned and fitted up the new de Beers Physical Laboratories, devoting his spare time to making them an outstanding monument to his wide experience and skill.

During his time in Cape Town, Ogg became interested in terrestrial magnetism, and when he retired from university life at the age of sixty-five he began a new one as director of the Government Magnetic Observatory, Hermanus, which again he planned and fitted up himself. Under his direction the Observatory has become well known internationally not only for its observations, which are considered to be among the most accurate in the world, but also for Ogg's papers on K indices of magnetic activity and on magnetic disturbances. He retired from the directorship in 1946, but maintained an active interest in the Observatory, as in all physical research in the Union, up to the time of his death.

The high standing of the subject of physics in South Africa is very largely due to Ogg's own high standards as a teacher and examiner. His students have become members of the staff of practically every university in the country, and his scholarly influence remains imprinted on both schools and universities. His time and energy, particularly in his early period, were so fully occupied with building up his departments that he had little available for research, though some valuable work on X-ray diffraction and crystal structure was done by him in Cape Town.

He was a fellow of the Royal Society of South Africa and its president for five years, a fellow of the Institute of Physics, the Physical Society, the Royal Microscopical Society and the Faraday Society. The University of Cape Town conferred on him the honorary degree of D.Sc. in 1936, and the University of Aberdeen that of LL.D. in the same year.

As a man, Ogg will be remembered for his kindliness and humour, his strict sense of justice and the great personal interest he took in his students. He always exercised an important influence on university affairs, an influence which was all the more effective because of his unassuming integrity.

B. F. J. Schonland

Mr. Harry Price

Through the death of Mr. Harry Price on March 29, psychical research has lost its most distinguished journalist and writer of popular descriptive accounts of adventures with the unknown. He was born in 1881, and from an early age was keenly interested in conjuring and magic, which soon led him to a desire to inquire more fully into the alleged physical phenomena of mediumship. An opportunity was given him in 1922 to visit Munich in order to be present at some sittings with the famous medium Willi Schneider, with whom the late Baron von Schrenck was at that time experimenting. From that period until the day of his death his interest in the problems of mediumship never weakened.

After the first properly equipped séance room had been built and opened by the Society for Psychical Research in February 1924, Mr. Price followed suit, and in December 1925 he opened what he called the National Laboratory of Psychical Research, with premises in the house of the London Spiritualist Alliance in South Kensington. From that date he pursued his inquiries and published his results with unremitting zeal and enthusiasm. His books and magazine articles were written in popular and colloquial style, and it was through them that many people became acquainted with psychical research who would otherwise have taken but little interest in the subject.

Mr. Price had a wide knowledge of his subject, and in course of time accumulated what is undoubtedly the finest collection of books on conjuring and allied arts that exists. This library he placed on permanent loan in the University of London, with the intention of bequeathing the entire collection, together with a sum of money for its maintenance, to the University. He had long hoped that a department for psychical research might be established in the University of London or elsewhere, and the negotiations in connexion with this project were long and protracted but never came to fruition. One of the reasons for this was that Mr. Price's interest in psychical research was much more that of a brilliant journalist seeking sensational copy than that of a sober man of science studying obscure phenomena away from the glitter of *klieg* lights and the hubbub of Press conferences. It was thus that many of his results were greeted with some suspicion, especially as some of the accounts of his own experiences were unverified and in many cases unverifiable. Yet his influence on contemporary psychical research was considerable, and his position in the field he made his own is not likely to be challenged for many years.

WE regret to announce the following deaths:

Sir Franklin Sibly, K.B.E., vice-chancellor of the University of Reading from 1929 until 1946, on April 13, aged sixty-four.

The Rev. Thomas Stephenson, a well-known amateur field botanist, on April 15, aged eighty-two.

NEWS and VIEWS

Félix Vicq d'Azyr (1748–94)

FÉLIX VICQ D'AZYR, who was born at Valognes in Normandy two hundred years ago on April 23, 1748, may properly be styled the greatest comparative anatomist of the eighteenth century before Cuvier. At the wish of his father, a doctor, he went to Paris at the age of seventeen to study medicine, remaining in the capital all his life. His social success and rapid rise to fame he is said to have owed to the French naturalist, Louis Jean Martin Daubenton, whose niece he married. He became permanent secretary to the newly founded Paris Academy of Medicine and succeeded Buffon in the French Academy. He was also consulting physician to the Queen. While his name is specifically immortalized in the 'band of Vicq d'Azyr' (also described by Gennari in 1782) and in the 'bundle of Vicq d'Azyr' (fasciculus mammillo-thalamicus), he made numerous exceedingly distinguished contributions to comparative and to human anatomy. Of particular importance is his comparative study of the limbs of man and animals, which stresses the correspondence between the flexor and extensor muscles of the legs and arms. In the troubled times in which his last years were spent he frequently risked death by attending patients on the proscribed list. He is believed to have caught a chill while watching the burning of the allegorical figure of atheism, and he died on June 20, 1794, at the early age of forty-six. Vicq d'Azyr's writings were published after his death by Moreau de la Sarthe under the title "Oeuvres de Vicq d'Azyr" (6 volumes), Paris, 1805.

Fuel Efficiency Committees

WHEN he opened the Wolverhampton Industrial Centenary Exhibition, Mr. Hugh Gaitskell, Minister of Fuel and Power, announced that he had reconstituted the Fuel Efficiency Committee organisation of the Ministry. This organisation consists of a central Fuel Efficiency Committee and a Fuel Efficiency Committee in each Region. The Fuel Efficiency Committee was first set up in September 1941, under the chairmanship of Dr. E. S. Grumell, who will continue as chairman. As now reconstituted, it will have the following terms of reference: "To advise on the application of measures promoting economy and efficiency in the use and consumption of fuel and power; to survey the progress of the organisations established for this purpose; to report the problems arising from these surveys which appear to require scientific investigation; to advise generally as to the lines on which a policy designed to raise the standards of utilization of fuel and power can best be implemented".

Many members of the previous committees have consented to serve on the new body. Other experts in different branches of fuel technology, and additional representatives of both domestic and industrial consumers have been invited to join. Liaison with both sides of industry will be ensured by the nomination of members of employers' and trade union organisations, and also with the Industrial and Domestic Coal Consumers' Councils, through their chairmen. The Regional Fuel Efficiency Committees are being reconstituted on similar lines, and their chairmen will be *ex officio* members of the main Committee. The committees consist entirely of voluntary unpaid workers.

Grants for Scientific Research in Belgium

THE annual report for 1946 of the Institute for the Encouragement of Scientific Research in Industry and Agriculture, Exercice, Brussels, details the twenty-nine projects for which subsidies were granted in 1946. The largest of these, 2,800,000 francs, was to the Electrical Construction Works of Charleroi, for research on electronic tubes and their applications; a grant of 2,458,000 francs was made to the Foundation for Potato Research for investigations on the breeding of varieties resistant to virus disease, and one of 2,000,000 francs to the Belgian Institute for High Pressures for static and dynamic researches in the field of high pressures, the development of methods for determining the quality of powders and explosives and the study of the metrology of high pressures. A further grant of 1,900,000 francs was made to the Electrical Construction Works of Charleroi for the continuation and extension of research on the mercury vapour arc, while the Belgian Institute for the Improvement of the Beetroot received 1,890,000 francs for continuing agronomic, chemical, biological and mechanical investigations on the improvement of the sugar-beet. To the Union of Belgian Artificial Textile Manufacturers, "Fabelta", 992,000 francs were granted for investigations on the determination of the properties of viscose filaments, and on the deformation of threads of regenerated cellulose. A grant of 891,000 francs was made to the National Research Centre for the Study of Animals Harmful or Useful to Agriculture, for the initiation of a study of the fauna, of means of controlling indigenous pests and nematode phytoparasites, as well as of biological control of agricultural pests. The Colonial Centre for Documentation and Co-ordination of Chemical Research received 844,400 francs for research in medicinal plants and insecticides in the Belgian Congo, while the Belgian Society of Optics and Precision Instruments received 800,000 francs for scientific and technical research on the improvement of optical surfaces, the study of optical systems corresponding with a new range of instruments and on the introduction of rational methods of manufacture into optics. Smaller grants, including 263,000 francs to the Centre for Ecological and Phytosociological Research and 162,500 francs for research on penicillin, brought the grand total to 20,801,300 francs.

Pulse-Counting Photometer

THE January issue of *Sky and Telescope* describes a new photo-electric photometer which counts the number of light pulses coming in from a star. The apparatus, known as the *RCA* 1*P*21 photo-multiplier tube, furnishes a strong pulse which can be amplified to operate special counters supplied by the Radio Corporation of America. In the 1*P*21 tube, each electron emitted when photons strike the light-sensitive surface in turn releases two to five secondary electrons from the first dynode, and repetition of this process through nine stages means that a single photon can be responsible for the emission of a million or more electrons from the last dynode. The addition of an *RCA* precision time-interval counter makes the work automatic; the observer merely sets a time-interval into a predeterminer, and the electronic devices then expose the counter to the output of the photomultiplier for a predetermined time. The number of pulses received in the interval is proportional to the light intensity of the star. Stars as faint as mag. 11·5 have been measured with the new apparatus attached to the 18-in. refractor of the Flower Observatory, and improvements now in progress may extend this by two magnitudes.

Head Wounds: Treatment and Rehabilitation

"WAR SURGERY SUPPLEMENT No. 1" of the *British Journal of Surgery*, with the subtitle "Wounds of the Head" (Bristol: John Wright and Sons, 1947. 30*s*. net), is not only a good record of surgical skill and achievement but also a fine example of British printing and publishing. Liberally illustrated by drawings and photographs, it should be a valuable work of surgical reference. There are twenty-two articles on various aspects of war wounds of the head. The first is by Geoffrey Jefferson, on "Head Wounds and Infections in Two Wars", the second by Sir Hugh Cairns on "Neuro Surgery in the British Army, 1939–45", and the third a remarkable "Atlas of Head Wounds", illustrating in colour standard operative techniques for their treatment. The remaining articles deal with other aspects of this important field of work and there are also notes on rare or obscure cases and a valuable bibliography of "Gunshot Wounds of the Head". Surgeons especially, but also bacteriologists, neurologists and others who are interested in the treatment and in rehabilitation of the patient after severe head injuries will certainly find the experience collected in this volume of very great value. They will look forward with great interest to the appearance of the three other war supplements which are being prepared. No. 2 of these will deal with Abdomino-thoracic Wounds, No. 3 with Wounds of the Extremities, and No. 4 with Plastic Surgery, including Facio-Maxillary Injuries.

Textile Institute

ACCORDING to the annual report of the Textile Institute, presented at the annual general meeting on April 21, membership increased during 1947 by more than 20 per cent, to 3,728; this is more than twice the 1943 total. Correspondingly, there has been a big increase in activity. Further new branches of the Lancashire Section were formed at Oldham and Burnley; sections and branches held more than a hundred meetings. Besides the very successful annual conference held at Portrush, two one-day conferences were held to consider "Modern Methods of Single Fibre Testing" and "End Breakages in Cotton Ring Spinning". Two scholarships were awarded, to Mr. G. H. Ewins and Mr. J. E. Booth, both of Bolton, who have now commenced degree courses in textiles at the Manchester College of Technology. The decision to award a new scholarship of a maximum value of £1,000, to be available to students in all branches of textiles, was also announced. It is hoped that the Institute will be able to ensure "the general recognition and application of technical skill and scientific knowledge within the textile industry on a scale adequate to enable the industry to maintain its place in the increasingly complex economy of a rapidly developing world. The Textile Institute must achieve the status and capacity which is required if textile technology, of which the Institute is the guardian, is adequately to meet the needs of modern times."

Health Education in Guildford

AN earnest attempt to combat infection of food and drink has recently been begun by the Guildford Health Committee and food traders of the town (*Health Educ J.*, 6, No. 1; January 1948). A preliminary survey of 317 food premises carried out in November 1946 by health officials showed that many premises were faulty in structure and had inadequate washing and cleaning facilities and were staffed by men and women who were daily committing unhygienic practices. Instead of using legislative powers to tackle the problem it was decided to gain the willing co-operation of the manufacturers and food handlers. A Guildford Hygienic Food Traders Guild was set up to improve the sanitary arrangements in food-handling premises and to ensure that the statutory standards of food hygiene are observed, as well as to establish codes of practice for different trades which would be voluntarily accepted and applied by member firms of the food trades guild. Time was given for the necessary alterations and improvements to premises to be made, and the scheme took effect from March 1. The support and co-operation of the housewife has been sought by educational propaganda.

Plant Collecting in the Far East

DR. GEORGE TAYLOR joined Frank Ludlow and George Sherriff in 1938 for an expedition to south-eastern Tibet, and an account of the journey has recently appeared (*J. Roy. Hort. Soc.*, **72**, Pts. 4 and 5, April and May 1947), with illustrations (several in colour) of some of the plants of significant horticultural beauty brought to Great Britain. Part of the collection is still unidentified; but the account seeks rather to portray those species which might attract British gardeners. The genus *Meconopsis* is perhaps most strongly represented, followed closely by *Gentiana*, but many other genera are mentioned. Mr. F. Kingdon Ward has also a recent short paper on his war-time explorations in Manipur (*J. Roy. Hort. Soc.*, **73**, Pt. 2, Feb. 1948). He noted many interesting plants and confirmed several earlier records by Watts and Clarke.

Natural History of Butterflies

A 20-page booklet on "Butterfly Migration" by Dr. C. B. Williams, in the "Young Britain" Educational Series of the *Daily Mail*, has recently come to hand. Simply but effectively written and attractively illustrated, it is a publication with an immediate appeal to young naturalists, if not to older ones also. The photographs of the living insects by S. Beaufoy add to its merits, and the chief facts relative to butterfly migration and what to look for in this field of natural history are clearly presented. Details regarding the various publications in the series are to be obtained from the *Daily Mail* School-Aid Department, New Carmelite House, London, E.C.4. The present booklet and many of the others are priced at 1*s.*; some cost a little more, but are excellent value at this low figure.

Archæology of the Missouri Valley

The Government of the United States is undertaking a large flood control and development programme in the Missouri Valley, and this will result in the destruction or submergence of many archæological sites which badly need study. Work in the area is a race against time, and "Prehistory and the Missouri Development Program", by W. R. Wedel (*Smithsonian Misc. Coll.*, **107**, No. 6), is a summary of what is already known about the archæology, together with an account of a preliminary survey, under the auspices of the Smithsonian Institution, done during the field season of 1946, in order to determine which sites ought to be excavated before they are overwhelmed.

A New Mathematical Journal

The Institute for Mathematics and Mechanics of New York University, of which the director is Prof. R. Courant, has now undertaken the production of a new journal entitled *Communications on Applied Mathematics*, which will appear quarterly. The publishers are Interscience Publishers, New York and London, and the subscription is eight dollars a year. The first number, dated January 1948, contains 99 well-printed pages, on good paper, with several diagrams. Most of it consists of an elaborate investigation of non-linear wave propagation in shallow water and open channels by J. J. Stoker. There is also a shorter paper on free boundaries of an ideal fluid by M. Shiffman. The second number will contain other papers on water waves. It is not intended that the new journal shall deal only with hydrodynamics; later numbers will cover a great variety of topics, including quantum theory, elasticity, aerodynamics, combustion, kinetic theory of gases, and the numerical solution of non-linear partial differential equations. Most of the papers will originate from the Institute for Mathematics and Mechanics of New York University.

International Society of Hematology

The International Society of Hematology will hold its bi-annual meeting in Buffalo, New York, during August 23–26. The provisional time-table allows for half-day sessions as follow: general subjects, including radioactive and stable isotopes in hæmatology; problems and diseases related to the red cells; problems and diseases related to the white cells; immunohæmatology, ***Rh–Hr*** (*CDE–cde*) antigens and antibodies, and hæmolytic anæmias (two sessions); coagulation problems and hæmorrhagic diseases. The chairman of the Programme Committee is Dr. Ernest Witebsky, Buffalo General Hospital, Buffalo, New York. Dr. Eduardo Uribe Guerola, Leibnitz 212, Nueva Colonia Anzurez, Mexico, D.F., is responsible for programme arrangements from South and Central America, and Sir Lionel Whitby, University of Cambridge, for papers from Europe. All scientific sessions and exhibits will be open to those interested in hæmatology. The secretary of the Society is Dr. Sol Haberman, William Buchanan Blood Centre, Baylor Hospital, Dallas, Texas, from whom further particulars can be obtained.

International Rheological Congress

An International Rheological Congress will be held at Scheveningen (The Hague) during September 21–24. The Congress will consider theoretical problems; fundamental experimental methods; rheological properties of various systems; rheological problems in biology; and industrial applications. The plasticity of crystallized materials, soil mechanics and geophysical problems will be excluded, since other international congresses will give attention to these subjects during the year. Sectional meetings for the discussion of special subjects will be a feature of the meeting; at these meetings, every speaker will give only a short account of his paper, so that ample time will be available for discussion. Manuscripts in English or French must be received before May 1. The maximum space for a paper is 2,500 words including formulæ and diagrams, since the *Proceedings* must be limited to 500 pages. Preprints of all papers will be available at least a month in advance of the meeting. Owing to generous support from Dutch industry and scientific societies, the congress fee will be 15 florins (about £1 8*s.*); this will cover the cost of preprints, but not the *Proceedings*. The Organising Committee will help participants in obtaining accommodation at Scheveningen. The secretary of the Committee is Ir. H. C. den Daas, Julianalaan 134 (Postbox 66), Delft.

Summer School in the Physics of Solids

A Summer School in the Physics of Solids, with particular reference to the properties of ionic solids, will be held in the H. H. Wills Physical Laboratory of the University of Bristol during September 8–15. Lectures will be given by Prof. N. F. Mott, Dr. J. W. Mitchell and other members of the staff of the Laboratory. A purely theoretical course on the electrical properties of ionic solids was held in 1946. The present course is intended for members of the staffs of Government and industrial laboratories who wish to familiarize themselves with both experimental and theoretical work on the properties of ionic solids, particularly in fields beyond those with which they are directly concerned. For each branch of the subject, parallel lectures will be given on the experimental side and on the theoretical side. Accommodation can be arranged at the University Hall of

Residence, Clifton Hill House. Inquiries should be addressed to the Director of the Department of Adult Education, W. E. Salt, University, Bristol 8; completed application forms should be returned by June 15.

Summer School in Metal Physics

A Summer School in Metal Physics will be held in the Cavendish Laboratory, Cambridge, during August 23–September 3. The School will provide an introduction to the application of physical methods to the examination and utilization of metals, and is intended for those whose researches require a more fundamentally physical approach than is usual in ordinary metallurgical and engineering practice. The lectures and demonstrations will deal with (*a*) application of X-ray methods in the examination of metals, (*b*) physical and mechanical properties of metals. Both parts will be taken by all attending the School, and for Part (*a*) an elementary knowledge of X-ray diffraction methods and of crystal symmetry will be assumed. A detailed syllabus and form of application for admission can be obtained from G. F. Hickson, Secretary of the Board of Extra-Mural Studies, Stuart House, Cambridge, to whom the completed application form should be returned not later than June 1.

University of London: Appointments

The following appointments in the University of London have been announced: Prof. A. C. Offord, professor of mathematics at King's College, Newcastle-upon-Tyne, since 1945, to the University chair of mathematics tenable at Birkbeck College as from October 1; Dr. R. E. M. Wheeler, director-general of archæology in India since 1944, to the chair of the archæology of the Roman Provinces tenable at the Institute of Archæology as from October 1; Miss Mary Barber, lecturer in bacteriology in the British Postgraduate Medical School, to the University readership in bacteriology tenable at St. Thomas's Hospital Medical School as from October 1; Dr. H. E. Rose, lecturer in mechanical engineering at King's College, to the University readership in mechanical engineering tenable at the College as from October 1.

The following titles have been conferred: professor of geology in the University on Dr. Leonard Hawkes (Bedford College); reader in organic chemistry in the University on Dr. A. H. Cook (Imperial College of Science and Technology); reader in chemistry in the University on Dr. H. G. Poole (University College); reader in agricultural chemistry in the University on Dr. R. L. Wain (Wye College).

The degree of D.Sc. has been conferred on Franz Bergel (Lister Institute of Preventive Medicine).

Colonial Service Appointments

The following appointments in the Colonial Service have been announced: J. L. Fleure, survey probationer, Malaya; R. W. Butler, veterinary officer, Tanganyika; R. M. S. Neave, veterinary officer, Kenya; D. Bradwell, analyst, Medical Department, Cyprus; R. L. Hartley, agricultural education officer, Fiji; C. W. D. Kermode, assistant conservator of forests, Tanganyika; J. P. Oliver, agricultural officer, Falkland Islands; L. Ross, assistant meteorologist, Nigeria; A. J. Willis, assistant meteorologist, Nigeria; E. W. Leach (deputy director of agriculture, Trinidad), director of agriculture, Trinidad; W. C. Muir (director of agriculture, Trinidad), director of agriculture, Tanganyika; F. W. Toovey (principal research officer, Oil Palm Research Station, Nigeria), officer-in-charge, Oil Palm Research Station, Nigeria; H. Fraser (assistant conservator of forests, Tanganyika), senior assistant conservator of forests, Tanganyika; H. R. Herring (assistant conservator of forests, Tanganyika), senior assistant conservator of forests, Tanganyika; A. L. C. Thorne (veterinary officer, Gold Coast), veterinary education officer, Nigeria; J. Y. Moggridge (entomologist, Tsetse Research Department, Tanganyika), director, Tsetse Research Control Department, Tanganyika; H. C. Smith (senior assistant livestock officer, Tanganyika), livestock officer, Tanganyika; J. F. B. Watling (senior inspector of produce, Nigeria), principal produce inspector, Nigeria.

New Satellite of Uranus

It is reported from the McDonald Observatory, Texas, that a new satellite of magnitude 17 to the planet Uranus was found on a plate taken on February 15, at the Cassegrain focus of the 82-in. telescope. Two other plates taken on March 1 confirmed the new discovery. Its distance from the planet is about 0·00082 astronomical unit, or 76,500 miles, which implies that its period of revolution is about 31 hours.

Acetylation of Sugars

Referring to the communication by S. D. Nicholas and Dr. F. Smith entitled "Acetylation of Sugars" (*Nature*, March 6, p. 349), Dr. P. H. Plesch, Chemistry Department, University of Manchester, remarks that the use of perchloric acid as catalyst in the acetylation of sugars is by no means new; it has been discussed in some detail by D. Krueger and W. Roman (*Berichte*, **69**, 1830 (1936) and *Angew. Chem.*, **47**, 58 (1934)).

Announcements

Mr. Norris E. Dodd, Under-Secretary of Agriculture in the United States, has been appointed director-general of the United Nations Food and Agriculture Organisation, in succession to Sir John Boyd Orr, who has retired. The British Minister of Food has agreed to release Sir Herbert Broadley, deputy secretary, Ministry of Food, for appointment as deputy director general of the Organisation.

The Fison Lectures of the Animal Health Trust will be delivered by Prof. L. Seekles, of the Veterinary Biochemical School of the University of Utrecht, at the Kingsway Hall, London, on May 10 and 12. He will discuss mineral disturbances in cattle, gastro-intestinal autointoxication in cattle and horses, and conditional deficiencies of trace elements in cattle. Further particulars may be obtained from the Animal Health Trust, 232–235 Abbey House, Victoria Street, London, S.W.1.

The Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland propose to award, for the next academic year, a limited number of postgraduate scholarships in husbandry, agricultural economics, statistics and agricultural and dairy engineering. Particulars may be obtained from the Secretary, Ministry of Agriculture and Fisheries, 2 Cambridge Terrace, Regent's Park, London, N.W.1, or the Secretary, Department of Agriculture for Scotland, St. Andrew's House, Edinburgh 1.

Erratum. In the note on "American Summer Scholarships for European Students" (*Nature*, April 17, p. 593), it should have been stated that applicants must be *less than* thirty-five years of age.

Purification of Anti-pernicious Anæmia Factors from Liver

We have now prepared from ox liver two red pigments both highly active in pernicious anæmia. The crude extract was purified by the methods employed by Emery and Parker[1] and then by repeated chromatography. Full details of these techniques will be offered for publication later. Recently we have used as starting material a proteolysed liver extract made on a manufacturing scale; this has given better yields of a product differing slightly in chromatographic behaviour, and of higher activity. Some preparations of both types have been separated by partition chromatography into two red fractions; the proportions suggest that one arises from the other by proteolysis.

The development of fractionation methods was made possible by the collaboration of Dr. C. C. Ungley, who carried out more than eighty clinical tests on our materials. After it became clear that activity and colour are inseparable, this property was used as a guide in cutting chromatograms. With the invaluable assistance of Mr. L. F. J. Parker, four tons of liver have to date been fully processed, yielding barely a gram of red materials from six separate lots of liver. The minimum effective single dose for the best four preparations from non-proteolysed liver are assessed at about 0·6 mgm., while proteolysed liver has yielded one preparation L.E.445 effective at 0·3 mgm. though not fully purified. It was also effective in three cases of subacute combined degeneration of the spinal cord. A recovery of about 25 per cent of the original clinical activity was achieved in this purification. Ten batches of red materials have all proved clinically active (twenty-six cases in all).

A recent preparation, which appeared to have reached the limit of purification by chromatography, was shown by electrophoresis on the Tiselius apparatus to be still not homogeneous. After the action of mixed bacteria, it was susceptible to further chromatographic purification. The resulting product had eight times the intensity of colour of L.E.445. It has not yet been tested clinically; if activity remains proportional to colour, it should be effective at 0·04 mgm.

The products are amorphous solids having about the colour of cobalt salts, but they show only general absorption of visible and ultra-violet light with very slight steps at 505 and 275 mμ. The low intensity of absorption precludes the presence of more than a few per cent of such bodies as folic acid or xanthopterin. Ultra-violet light produces a very faint blue fluorescence (probably due to a trace of impurity); this is abolished by hydrosulphite, while the colour shows only a slight change of shade. Dr. R. A. Kekwick at the Lister Institute kindly examined a sample in the ultra-centrifuge and reported no sedimentation boundary even at 250,000 *g*, suggesting a molecular weight well below 10,000. The diffusion method has indicated molecular weights of about 3,000 for the pigments from both proteolysed and non-proteolysed liver. We are indebted to Dr. J. E. Page for these determinations and also for polarographic examination and electrometric titration, neither of which revealed any characteristic steps. The optical rotation of various imperfectly purified specimens has ranged from $[\alpha]_D - 150°$ to $-200°$. There is a gradual change in colour from red to orange on exposure to daylight, accompanied by a marked change in chromatographic behaviour.

Our products are exceedingly soluble in water and not readily salted out; they are also soluble in nearly anhydrous alcohol, in acetone containing only a few per cent of water, and in glacial acetic acid; but not in ether, chloroform or non-polar solvents.

Chemical examination has not proceeded very far. Various lots have contained 11·7–13·9 per cent nitrogen. Washing a solution in phenol with dilute acid removed calcium and a little sodium; the phenol solution left a negligible ash. Amorphous precipitates are given by Reinecke acid, rhodanilic acid and phosphotungstic acid. Warm dilute alkali has no effect on the colour, but boiling normal soda quickly destroys it. On the other hand, the colour is remarkably resistant to acid hydrolysis and partially survives boiling with 6 *N* hydrochloric acid for twenty-four hours. After boiling with *N* hydrochloric acid for one hour the pigment is very readily extractable by *n*-butanol. From 23 to 50 per cent of the original weight appeared in the butanol extract, depending on the purity of the preparation. It appears to contain two pigments, one acidic and readily extractable from the butanol with aqueous alkali, the other neutral; the latter is readily soluble in chloroform, the former only slightly; both are insoluble in ether; neither is identical with the photolysed product. These substances have not as yet been examined further.

The residual aqueous acid layers have contained peptides; after further acid hydrolysis these have been examined by Mr. G. A. Childs and Dr. W. F. J. Cuthbertson, by chromatography on paper and (after acetylation) on silica, and by microbiological assay, respectively. Proline, hydroxyproline, leucine, serine, glutamic acid, and *p*-aminobenzoic acid have been detected; but differences in the results for different preparations make it probable that some of the amino-acids arise from peptide impurities.

The following conclusions appear warranted. Our two pigments are differing forms of the classical liver factor first postulated by Minot and Murphy twenty-two years ago[2], and not some incomplete substitute, such as folic acid or thymine. Whatever deficiencies may be found with other macrocytic anæmias, true pernicious anæmia and its associated neurological disturbances do not require a multiplicity of factors as postulated by Jacobson and SubbaRow[3] and others, but respond to a single factor. With an effective dose equivalent to some 20 μgm. daily (possibly 2·5 μgm. only) this is one of the most potent of known physiologically active substances.

Addendum. Since this letter was written, we were privileged, through the courtesy of a confidential disclosure by Dr. R. T. Major of Merck and Co., Inc., Rahway, New Jersey, to read prior to publication the paper by E. L. Rickes, N. G. Brink, F. R. Koniuszy, T. R. Wood and K. Folkers (*Science*;

in press), on the isolation of crystalline vitamin B_{12}, which appears to be the pure anti-pernicious anæmia factor.

A New Extraction Procedure for the Preparation of Heparin

THE usual method of preparing heparin, due to Charles and Scott[1], involves rough extraction of tissues with alkali and subsequent tryptic digestion of the protein precipitate.

Special investigations, which will be reported elsewhere, made it highly desirable to prepare heparin by means of milder extraction methods avoiding the use of alkali. For this purpose, a number of salt solutions of different concentrations were tested. A 10 per cent calcium chloride solution, as used by Meyer *et al.*[2] for the extraction of chondroitin sulphuric acid, proved to be ineffective, and so did several other salt solutions. It was found that solutions of potassium thiocyanate exert a pronounced power of extracting fairly quickly and completely the mast cell granular substance from various tissues (liver and skin). Using *M* potassium thiocyanate solution for twenty-four hours, we obtained about 90 per cent extraction of the metachromatic material in ox liver. Histochemical examination of the tissue residues (cf. Sylvén[3]) showed only insignificant amounts of metachromatic substances left after such extraction. Metachromatic material was not found to adhere to other constituents, such as collagen, as it often does when previous methods are used.

After the extraction, the potassium thiocyanate was readily removed by dialysis. The following fractions then remained to be analysed: tissue residue, precipitate, supernatant and dialysate. The different fractions were treated by tryptic digestion according to Charles and Scott, and the heparin contents were assayed by estimating the anticoagulating effect by means of the thrombin method according to Jaques and Charles[4]. The following amounts of heparin expressed in mgm. 'standard heparin' according to Jorpes[5] were found:

	Amount of heparin obtained from ox liver
Tissue residue	5·5 mgm./kgm.
Precipitate	56·3 ,,
Supernatant	0 ,,
Dialysate	0 ,,
	Total 61·8 ,,

Obviously, the extracted substances displaying heparin activity were precipitated following the removal of thiocyanate. The heparin precipitated during dialysis seems to be bound to proteins. The complex is split by trypsin treatment, and afterwards almost all the heparin can be recovered. The collected yield tallies well with that reported by Wilander[6] (56–75 mgm./kgm. ox liver).

The properties of heparin prepared in this way will be described elsewhere.

We wish to express our thanks to the Consul General, Axel Ax:son Johnson, Stockholm, for financial support.

Effect of Thyroid Deficiency on the Level of Pseudo-Cholinesterase in the Plasma of Rats

THE effect of thyroid deficiency on the level of pseudo-cholinesterase in rat plasma has been examined in the following experiments.

Adult male Wistar rats (200–400 gm.) were used. They were maintained on a diet of chow ('Purina') which has been shown to be adequate for normal growth in the rat colony. All animals were killed by exsanguination through the jugular vein, and plasma from the oxalated blood was used for estimating pseudo-cholinesterase activity. The determinations were carried out by the method previously described[1]. Group I consisted of twenty-seven normal animals which served as controls. Group II was made up of sixteen animals which survived thyroidectomy. In this operation the removal of varying amounts of parathyroid tissue could not be avoided. To offset the effects of parathyroidectomy, daily subcutaneous injections of 2 ml. of a 5 per cent calcium gluconate solution were given for a period of seven days. The animals were killed fourteen days after operation; this time interval seems sufficient for the recovery of the level of pseudo-cholinesterase from the transient decline resulting from surgical intervention[2]. To exclude the possibility that the effects observed were due to parathyroidectomy rather than thyroidectomy, a third group of fifteen rats was treated with thiouracil. These rats received for a period of 23–27 days a water ration containing 0·06 per cent thiouracil. With an average daily intake of 20 ml. of water, the thiouracil consumed by each rat was thus in the neighbourhood of 12 mgm. a day.

It will be seen from the figures in the accompanying table that thyroidectomy and treatment with thiouracil cause an increase in the level of the pseudo-cholinesterase of the plasma.

LEVEL OF ACTIVITY* OF PSEUDO-CHOLINESTERASE IN THE PLASMA OF MALE RATS

Group	Normal I	Thyroidectomized II	Thiouracil-treated III
Number of animals	27	16	15
Average activity	41·0	97·1	117·3
Standard error	2·3	8·7	10·6

* µl. Carbon dioxide evolved by 1 ml. plasma in 20 minutes. Substrate: benzoylcholine chloride (0·006 *M*).

A statistical analysis of the results obtained reveals that the probabilities for the differences in pseudo-cholinesterase activity arising on a basis of pure chance are: for Groups I and II, $2 \cdot 0 \times 10^{-9}$; for Groups I and III, $2 \cdot 6 \times 10^{-12}$; and for Groups II and III, $1 \cdot 3 \times 10^{-1}$. Thus the differences between the levels of pseudo-cholinesterase in the plasma of normal and thyroidectomized and of normal and thiouracil-treated animals are highly significant, whereas the difference between the effect of thyroidectomy and treatment with thiouracil is of doubtful significance.

Since the physiological function of the pseudo-cholinesterase is still obscure, any attempt to interpret the results outlined above would seem premature. This investigation is being continued and the experimental findings will be discussed in greater detail elsewhere.

This research was aided by a grant from the Banting Research Foundation to one of us (M. N.).

Phase Memory of the Ear: a Proof of the Resonance Hypothesis

No experiment has hitherto been recorded which is decisive for or against the resonance hypothesis. The properties of the ear are such that it is difficult to construct an experiment of which the result is neither obscured by an unavoidable margin of error nor capable of alternative interpretations. We believe that the following experiment is unobjectionable on either of these grounds and constitutes a valid proof that the resonance hypothesis is true, and that the resonators of the ear (at all but the lowest audible frequencies) are only lightly damped.

We present to the ear of an observer two alternative stimuli. One stimulus consists of a train of oscillatory pulses of sound, each pulse of the form $F \sin 2\pi ft$ and n cycles duration separated from the next by a silent interval of length corresponding to m cycles, n and m being integers. The other stimulus, which can be substituted for the first by the operation of a single switch, is identical in all respects save that the phase of alternate pulses is reversed. Precautions are taken to ensure that the wave-form of the sound in air corresponds with high accuracy to the intended wave-form. If the observer can distinguish between the two stimuli, it follows that the oscillations in the ear initiated by each pulse have not died down to insignificance at the onset of the next, for the energy of every pulse of both stimuli is identical in magnitude and spectral distribution. No frequency analyser could distinguish between the two stimuli unless its oscillatory time constants were so large that phase was 'remembered' across the silent interval.

We find, for example, that at a frequency, f, of 5 kc./s., an intensity of about 20 db. above threshold and n approximately 10 (the value of n is not critical), the stimuli are readily distinguished provided that m is not much greater than 30. The energy in a resonator decays at the rate of $\frac{20\pi}{Q} \log_{10} e$ db. per cycle ($\doteqdot \frac{27}{Q}$ db. per cycle), where Q defines the degree of resonance in the usual way. It is evident that if Q were low, say, 10, the residual energy at the end of a silent period of 30 cycles would be insignificant (40 db. below threshold). The only explanation of the result is that at this frequency the value of Q must be so high that the residual energy at the end of the silent period is a significant fraction of the energy available from the next pulse. This indicates a value for Q of at least 100 and probably substantially more.

We have published[1] an estimate of Q for the resonators of the ear by a different method, giving a value of about 250 at 5 kc./s. The experiment described above constitutes a proof that our previous interpretation was correct, and that in fact it was the Q of the resonant elements which we determined and not, as has been suggested, a time constant associated with some subsequent process in the chain which results ultimately in a sensation in consciousness. It also strongly supports the conclusion that, in essence, Helmholtz's interpretation of the structure of the ear was correct[2]. Consequently the results of experiments which have been interpreted as indications that the resonators of the ear were highly damped must be re-examined. So far as we can see, an alternative explanation consistent with the resonance hypothesis is in every case the probable one.

One of us (T. G.) was assisted by a grant from the Medical Research Council.

Osmotic Work Performed by the Renal Tubules

A method for the derivation of an 'index of renal tubular activity' has recently been suggested by Barclay and Kenney[1]. An alternative method of deriving this index, which is suggested in this note, lends support to Barclay and Kenney's claim that their ratio represents tubular activity.

Consider a small region of the tubule, where the concentration of the solute in the tubular urine exceeds the concentration of the same solute in the plasma by a small amount, dC'. Let the osmotic pressure difference between the plasma and the tubular urine in this region be equal to p', for this particular constituent solute.

Then:

$$p' = RT.dC',$$

where R is the gas constant, and T the absolute temperature.

Now the work performed in withdrawing a volume of water, dv, against this osmotic pressure, p', is

$$w' = RT.dC'.dv.$$

To obtain the total work performed along the whole length of the tubule, we can take the sum of the work done in the regions from the glomerulus to the end of the tubule: that is, from the region where $dC' = 0$, to the region where $dC' = (U' - P')$, U' and P' being the concentrations of the substance in the urine and plasma, respectively.

If the work done along the whole length of the tubule is summed, the value of dv may be written as a constant, k; and dC' becomes $(U' - P')$. If this value for the work along the whole length of the tubule is referred to a constant rate of filtration of the solute under consideration, we can obtain an expression for the total work, per mole of the solute filtered :

$$W_0' = RT.k.(U' - P')/G.P', \qquad (1)$$

where G represents the glomerular filtration-rate.

Similarly, for a second solute :

$$W_0 = RT.k.(U - P)/G.P. \qquad (2)$$

Therefore the ratio of the osmotic work performed in withdrawing water against the osmotic pressure of the second solute to that performed in withdrawing water against the osmotic pressure of the first is given by :

$$W_0/W_0' = P.P'(c - 1)/P'.P(c' - 1),$$

where $c = U/P$ and $c' = U'/P'$.

$$\text{Hence } W_0/W_0' = (c - 1)/(c' - 1). \qquad (3)$$

Where the 'reference solute', represented above by U', P', etc., is a substance which is neither excreted nor reabsorbed by the tubule cells, this ratio becomes identical with that proposed by Barclay and Kenney.

The above equations hold in the case of non-electrolytes. For electrolytes we must consider the activity coefficient. For two electrolytes having the same values for activity and dissociation, equation (3) above will hold. If we consider any electrolyte, and compare it with a reference solute, such as inulin, we are fulfilling the conditions under which the index of Barclay and Kenney is applied.

This would indicate that the index, E, referred to above, represents the ratio of the osmotic work performed in withdrawing water against the osmotic pressure of a particular solute, to that performed in withdrawing water against the osmotic pressure of a solute which is neither excreted nor reabsorbed by the renal tubules.

White-eyed Mutants of Diptera

RECENTLY, Sturtevant[1] has criticized work on white-eyed mutants of *Culex*[2], *Calliphora*[3] and *Phormica* (= *Phormia*)[4], on the grounds that such mutations are not comparable with white-eyed types in *Drosophila*. Sturtevant claims that while there are two pigments, a red and a brown, in the wild-type eye of *Drosophila*, there is only one pigment, a brown, in *Calliphora*, and that this is the usual condition in insects. Thus, the wild-type eye of *Calliphora* would be like the brown mutant of *Drosophila* in which red pigment is absent ; and, moreover, in that case it would not be possible to distinguish morphologically white, vermilion, cinnabar and scarlet mutants in *Calliphora* or in other Diptera in which red pigment is not present in the wild-type eye. In support of this view, Sturtevant quotes the work of Becker[5] on the eye-pigments of Arthropods.

Microscopical examination of the wild-type eye of *Culex pipiens* confirms the absence of red pigment granules in this species ; but it is only necessary to tease out in saline and examine microscopically an adult wild-type eye of *Calliphora erythrocephala* to prove conclusively that abundant red pigment granules are present. In a paper now in the press[6], I have shown that during pupal life the sequence of pigment formation in *C. erythrocephala* is yellow, brown and red. Moreover, there is a close parallelism between *Drosophila* and *Calliphora* both in the sequence of development of pigment granules and in the distribution of the different types of granules in the various pigment cells of wild-type eyes, except that in *Calliphora* the late-phase deposition of pigment and the appearance of red granules do not occur until a few hours before the emergence of the adult fly (at 24° C.). In the mature wild-type eye of *C. erythrocephala*, red pigment granules are present in the basal regions of the primary pigment cells and are densely packed throughout the body and fringes of the secondary pigment cells. Brown pigment granules are densely packed throughout the primary pigment cells except for their basal regions, but occur only in the distal tips of the secondary pigment cells.

I have shown[7] previously that the nature and location of the red and brown pigments in *Calliphora* render possible the occurrence of 'red' mutants as in *Drosophila* ; but this paper, which followed that in which the white-eyed mutant of *Calliphora* was described[3], apparently has been overlooked by Sturtevant. It was shown that, in certain circumstances, namely, keeping developing pupæ at about 4° C., it is sometimes possible to induce the formation of red pigment granules in the eyes of white-eyed mutant females of *Calliphora*. In such cases red is present in the absence of brown pigment, and the eye of the adult female is 'pink' or 'red'. This shows that potentially the 'red' series of mutants is possible in *Calliphora* in the absence of brown pigment ; and, presumably, in the absence of 'red', a series of brown mutants could appear. Finally, the absence of *both* red and brown pigments gives the white-eyed mutant.

It can be concluded, therefore, that in the wild-type eye of *Calliphora erythrocephala* both red and brown pigment granules are present. In mutant forms the red pigment may be present in the absence of brown. In the white-eyed mutant both red and brown pigments are absent. There is a close parallelism between the type, development and distribution of pigment granules in wild-type eyes of *Drosophila* and of *Calliphora*.

There is thus no basis for the contention of Sturtevant that the white-eyed mutation which I have described in *Calliphora erythrocephala* is not comparable with white-eyed types in *Drosophila*. The main interest, however, of the white-eyed mutant of *Calliphora*, as I emphasized in previous papers, is that, in spite of the similarity to *Drosophila* in details of type and distribution of pigment granules and in the location of the mutant gene in the X-chromosome, there is a fundamental difference in the mode of inheritance of the mutant gene in *Calliphora*. The white-eyed gene in *Calliphora* is sex-linked, as in *Drosophila* ; but, as I have shown[3], it is unique among known eye-mutants of *Diptera* in being sex-limited and appearing only in the double recessive female. This sex-limitation is due to the presence of an allelomorph for wild-type eye in the Y-chromosome, which is dominant over the recessive mutant gene in the X-chromosome. The male *Calliphora*, therefore, never manifests the white-eyed character even when it carries the mutant gene in the X-chromosome of the XY pair in this sex. In Diptera the only other comparable cases of sex-limitation of mutant genes, caused by the presence of normal allelomorphs in the *Y*-chromosome, are the mutant 'bobbed' described by Mohr[8] in *Drosophila melanogaster* in 1923 and the 'lethal' described by Schubel[9] in 1934 in the same species.

Action of Heating on *Rh*-Positive Human Red Cells

Lubinski and Portnuff[1] have demonstrated that heating at 56° reduces or destroys the agglutinability of *Rh*-positive cells by anti-*Rh* sera. They have studied also the action of diluted formalin, which seems to be somewhat similar. Many workers have observed that preservation in saline affects the *Rh*-positive cells in the same way and recommend the use of fresh suspensions when performing *Rh*-testing.

These facts lead to the idea that the *Rh* receptor is probably more superficial or fragile than the *A* and *B* receptors, for example. We have tested this idea by the following experiment: 1 ml. of *O Rh*+ (*CDe, cDE*) cells are washed three times and suspended in an equal volume of saline adjusted to *p*H 7·2. The mixture is heated for fifteen to twenty minutes in a water-bath at 56° C., and the cells separated from the medium by centrifuging. The cells are washed three times and distributed in a series of titrations with a powerful anti-*Rh* (anti-*D*) serum. Controls are made with unheated *Rh*+ and *Rh*− (*cde, cde*) cells and with heated *Rh*− cells. It is easily verified that heating abolishes the agglutinability of the *Rh*-positive cells. The supernatant fluid to both *Rh*+ and *Rh*− heated cells is mixed with an equal volume of anti-*Rh* serum and allowed to stand at room temperature for half an hour. The two mixtures are then titrated in saline with fresh *Rh*-positive cells. In these conditions, a marked inhibition effect takes place in the first series (supernatant fluid of *Rh*+ cells), while the second shows no evident change in the anti-*Rh* titre.

This experiment was performed with several anti-*Rh* sera, and the same results were obtained.

It appears that heating at 56° C. affects the agglutinability of *Rh*-positive cells by splitting off from the surface of the cell a substance which diffuses in the medium; this may prove to be the *Rh*-receptor.

We are indebted to Dr. R. R. Race and A. E. Mourant for having given us the test-sera used in the genotype determination.

A Method for Estimating Percentage Germination of Fungal Spores

METHODS previously used for estimating the percentage germination of fungal spores have involved hanging-drop or slide cultures. The environmental conditions, when using these methods, have always been difficult to standardize, though it may be argued that for pathological work they simulate those existing on the surface of fruits and leaves.

We have evolved, during fermentation studies, a method which could be applied to fundamental investigation of the physiology and biochemistry of spore-germination. This method possesses the following advantages: (*a*) conditions are readily standardized; (*b*) it is rapid and easily operated; (*c*) large serial samples can be taken from the same population; (*d*) the samples can be kept for further reference.

The technique involves addition of spores to a liquid nutrient medium contained in a plugged vessel so that the final concentration is not less than 1×10^6 spores per ml. of medium. The vessel is shaken on a rotary or reciprocal shaking machine at a known temperature, and samples are taken at intervals. The spores in the samples are fixed and afterwards examined as convenient.

The degree of accuracy of this method is illustrated by the results of the following typical experiment. Conidia of *Penicillium chrysogenum Q* 176 were used. Each of eight 750-ml. conical flasks containing 100 ml. of a nutrient medium was inoculated with 1×10^8 conidia. The flasks were maintained at 24° C., on a rotary shaker. Later, when germination was about 50 per cent, three samples were taken from each flask and fixed in 10 per cent formalin. Three counts per sample, each of about 500 spores, were made.

A statistical analysis of the results showed that no significant variation existed between the repeat samples from the flasks, the repeat counts per sample and the mean count from flask to flask. The variation between the nine counts within each flask was not greater than the theoretical error of counting[1]. The conidial suspension was thus uniform, was capable of accurate sampling and remained stable. The theoretical standard error of percentage germination is $100\sqrt{n(N-n)/N^3}$, where N is the total number of spores counted and n is the number germinated. For the results of this series, this was approximately 2·2 per cent actual.

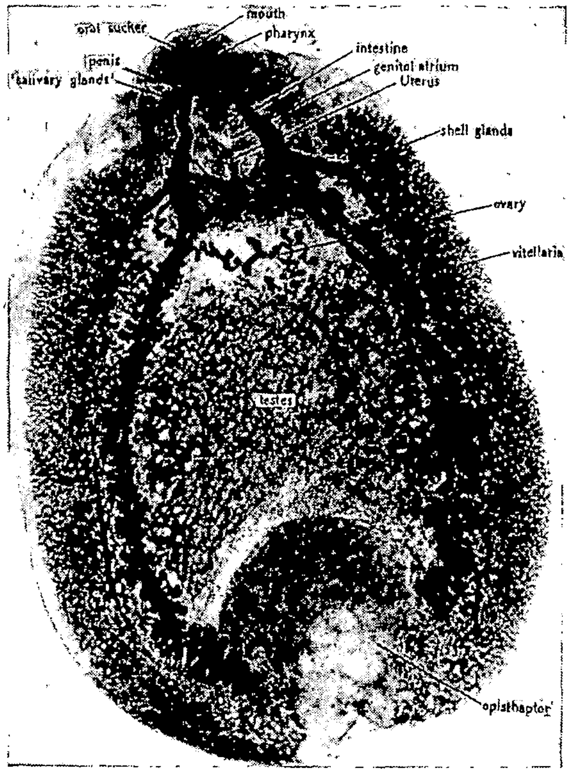
A Rare Cœlom-Dwelling Trematode

CŒLOM-dwelling trematodes are very rare. The only monogenetic form ever found in the cœlom of a vertebrate is *Dictyocotyle cœliaca* Nybelin, 1941. A solitary specimen was found at Göteborg on April 1, 1940, attached to the surface of the liver in a ray (*Raja lintea* Fries) caught the previous day near Skagen. At first sight the trematode was mistaken for the well-known cloacal parasite *Calicotyle kroyeri*, but closer inspection revealed several distinctive characters, notably the irregular arrangement of numerous



Calicotyle cœliaca; FIRST SPECIMEN. NEGATIVE PREPARED BY MESSRS. H. MALIES AND M. V. SALMON; PRINT BY WALLACE HEATON, LTD.

shallow loculi on the posterior disk (opisthaptor), which was devoid of hooks, the reticular nature of the testes and the five finger-like terminations of the filiform ovary[1]. In contrast, the opisthaptor of *Calicotyle* has one central loculus and seven peripheral loculi and bears one pair of hooks with recurved points, the testes are diffuse and follicular and the ovary terminates in a single lobe.

A second specimen was afterwards found among specimens of *Calicotyle kroyeri* in the Natural History Museum, Göteborg. It had been found by Swenander thirty-five years earlier in the cœlom of a starry ray (*Raja radiata* Donovan) caught near Trondhjem, and was somewhat deformed. Three specimens found several years later at Cambridge on the liver of a young skate (*Raja* sp.) obtained from Plymouth were mature but mutilated, each of them having lost the opisthaptor[2]. Thus, until the present time, only one good specimen of this species was known.

In my recent book[3] I commented on the difficulty of resolving the taxonomic status of *Dictyocotyle cœliaca*, which I chose to regard as an abnormal form of a species of *Calicotyle*, probably *C. kroyeri*, which had entered the cœlom of the host by way of one ot the abdominal canals and had either failed to perfecf the larval haptor normally or else regenerated an abnormal haptor after losing the normal one. In the absence of young forms we cannot improve on these speculations; but as two new adult specimens have turned up in Britain, some further comments are called for. The specimens came to me as stained whole mounts through the courtesy of Mr. Eric B. Francis, from the Zoological Laboratory, University of Sheffield. They were found on the outside of the stomach in a thornback ray (*Raja clavata* L.) during the course of a dissection. About twenty other rays of the same batch (believed to have been landed at Brixham) were examined for similar parasites, but without success.

Both specimens are somewhat larger than Nybelin's specimen *A*, being 8·3 mm. and 8·1 mm. long and 6·3 mm. and 6·0 mm. broad (0·76 and 0·73 body-length), but smaller than his specimen *B* which, to judge from a figure and scale, must have exceeded 11 mm. in length. The unarmed, multiloculate opisthaptor is about 2·5 mm. in diameter (0·3 body-length) in each specimen, that is, relatively large, and the oral sucker is about 1·0 mm. broad and 0·7 mm. long. In other respects the specimens display the distinctive characters described by Nybelin; the reticular testes occupy most of the space available in the mid-body, and in front of them is seen the thread-like ovary with its five almost spherical terminations, each about 0·1 mm. in diameter (see reproduction). Other characters include well-developed glands associated with the base of the pharynx, the mean size of which is 0·42 mm. × 0·37 mm., intestinal crura with short and simple diverticula and also larger, compound outgrowths in the posterior region, well-developed vitellaria and shell glands, a common genital atrium and pore, complicated male genital organs—including a cuticularized penis—and a pair of vaginæ. What is almost certainly an extruded egg is caught on a fold of the body margin in one specimen; it is pyriform, measures 0·186 mm. × 0·100 mm. and has a single polar filament 0·019 mm. long.

With this confirmation of Nybelin's observations on the cœlom-dwelling trematode from rays captured in the Skager Rak, the North Sea and the English Channel comes the conviction that it deserves the status of a species, but is a species of *Calicotyle*, namely, *C. cœliaca* (Nybelin, 1941). The location in the host indicates only deeper penetration, for *C. kroyeri* and *C. affinis* enter the rectum and rectal gland of *Chimæra monstrosa*, *C. stossichi* enters the rectum of *Mustelus lævis* and *C. inermis* and lives in the oviducts of *Pristiophorus cirratus*. The absence of hooks on the opisthaptor is also a character of the last-named species. Little can be said at present about the loculi on the opisthaptor, except that they number about one hundred and vary in degree of development (see reproduction).

For further study of this obscure and interesting trematode new specimens are needed, particularly young forms, and I hope that a look-out will be kept for them not only in the cœlom, but also in locations such as the rectum and the oviducts, in laboratories where skates and rays are dissected.

Interspecific Fertilization in Ascidians

THE only experimental work on interspecific fertilization in Ascidians known to me is that of Reverberi[1], who succeeded in fertilizing *Ciona intestinalis* eggs with *Phallusia mamillata* sperms after removal of the egg membranes. He availed himself of Morgan's observation that in *Ciona* only the egg membranes oppose self-fertilization.

Following Prof. Reverberi's suggestions, interspecific crosses have been tried between eggs and sperms of five species of Ascidians : *Ciona intestinalis* (Lin.) ; *Phallusia mamillata* (Cuv.) ; *Ascidia malaca* (Traust.) ; *Ascidia mentula* (O. F. Müller) ; *Ascidiella aspersa* (O. F. Müller). The experiments were carried out during September–December, 1947, at the Zoological Station of Naples.

Egg membranes were removed by means of steel needles ; chemical methods (such as digestion by enzymes from Decapod hepatopancreas) were avoided in order not to modify the egg cortex. The preliminary results may be summarized as follows.

Fertilization with heterospecific sperms succeeded in every case, except where *Ascidiella* sperms were used : it was observed that these sperms very rarely fertilize eggs of their own species after removal of the egg membranes. Probably this result is connected with the fact that *Ascidiella* eggs, which normally are buoyant, sink when their membranes are removed. The percentage of fertilized eggs varied considerably in the different kinds of crosses, but was fairly constant in experiments with the same cross. The lowest percentage was obtained with *Ciona* sperms.

In no case did interspecific fertilization succeed with eggs still inside their membranes, in spite of the fact that in certain species (*Phallusia* ; *Ascidia mentula*), unlike *Ciona*, self-fertilization is a normal process.

Time intervals between sperm addition and actual fertilization varied widely, even in the same experiment (from a few minutes, as normal, to more than twenty-four hours). This result is perhaps correlated with enzymatic activity of the sperms. Sperms of the same *Ascidiella* specimen clotted constantly around the eggs of certain species (*Phallusia* ; *Ascidia malaca*), but not of others (*Ascidia mentula*).

In a high percentage of cases fertilized eggs developed. In the following cases normal tadpoles were obtained : ♀ *Phallusia* × ♂ *A. mentula* (27 per cent) ; ♀ *A. malaca* × ♂ *Ciona* (7·7 per cent) ; ♀ *A. malaca* × ♂ *Phallusia* (68·5 per cent) ; ♀ *A. malaca* × ♂ *A. mentula* (83 per cent) ; ♀ *A. mentula* × ♂ *Phallusia* (11 per cent). These larvæ showed only maternal characters. The development-rate was always that characteristic of the maternal species. The larvæ did not metamorphose, probably due to culture conditions ; but sometimes tail resorption occurred.

In the other cases, a tadpole stage was not reached. But gastrulation took place (apart from ♀ *A. mentula* × ♂ *Ciona*, where the eggs were only abnormally activated), and in a few cases some differentiation was observed (testal membrane, superficial pigment spots).

Cytological study of the material has not yet been made, so it is not possible to decide whether true hybrids were obtained or development was parthenogenetic. In most cases two polar bodies were extruded, and in some the conjugation of pronuclei was actually observed.

Toxicity of Azo-Compounds and Other Substances to the Fruit Tree Red Spider Mite

LITTLE is known of the susceptibility to synthetic organic substances of the summer stages of the fruit tree red spider mite, *Metatetranychus ulmi* (Koch) (syn. *Paratetranychus pilosus* C. and F.), although recent work on this pest[1], and on the related mite *Tetranychus telarius* L.[2-5], has suggested that azobenzene is appreciably toxic. Consequently, we have recently examined in the laboratory, using *M. ulmi* as a test-organism, a series of compounds related to azobenzene, with the view of investigating the relation between toxicity and chemical structure.

A group of twenty-eight compounds was tested against the summer eggs on one hand and the adult female stage on the other; and, on arranging the compounds in order of toxicity, no well-defined parallelism was evident between the two series. There are, however, individual exceptions to this : notably, azobenzene, azoxybenzene and benzyl benzoate appear appreciably toxic to both stages, whereas 4-hydroxy-azobenzene, 4-amino-azobenzene, benzene-azo-*o*-cresol, diphenyl urea and diphenyl thiourea have little effect on either stage. The effect of substitution in the benzene nuclei has not yet been investigated in detail, but in the few cases examined such substitution products are less toxic than the parent compound. Thus, 4-amino-azobenzene, 4-hydroxy-azobenzene, 3 : 3′-dimethyl-azobenzene and benzene-azo-*o*-cresol are far less toxic than azobenzene, while 4 : 4′-diamino-diphenyl and benzaldehyde 2 : 4-dinitrophenylhydrazone are less toxic than diphenyl and benzaldehyde phenylhydrazone.

The azo-group does not appear to be essential to toxicity, since it may be replaced without loss by a variety of other atomic groupings. On the other hand, there is evidence that the precise nature of the grouping is of importance, and the accompanying table shows the toxic effect of compounds containing various alternative linkages between the two benzene nuclei.

EFFECT ON TOXICITY OF ALTERING THE BRIDGING GROUP BETWEEN TWO BENZENE NUCLEI

Toxicity	Alternative bridging group	
	Summer egg	Adult female
As toxic as azobenzene	$-CO-O-CH_2-$ $-\overset{\overset{O}{\|}}{N}=N-$ $-SO_2-$ $-\overset{\overset{NO}{\vert}}{N}-$ $-NH-NH-$	$-CO-O-CH_2-$ $-\overset{\overset{O}{\|}}{N}=N-$ $-CH=N-NH-$
Somewhat less toxic	$-CH_2-NH-CH_2-$ $-CH=CH-$ $-CO-O-$ $-CH_2-CH_2-$ $-NH-$	$-CH_2-NH-CH_2-$ $-NH-NH-$ $-CO-CO-$
Appreciably less toxic	$-CH=CH-CO-$ $-O-$ $-CH=N-NH-$ $-N=N-NH-$ No bridging group (diphenyl)	$-CH=CH-CO-$ $-O-$ $-NH-$ $-CO-O-$ $-CH=CH-$ $-\overset{\overset{NO}{\vert}}{N}-$ $-CH_2-CH_2-$ $-SO_2-$ $-CH(OH)-CO-$
Much less toxic	$-CO-CO-$ $-CH(OH)-CO-$ $-NH-CO-NH-$ $-NH-CS-NH-$	No bridging group (diphenyl) $-N=N-NH-$ $-NH-CO-NH-$ $-NH-CS-NH-$

It will be noted that, under the conditions of our tests, azoxybenzene and benzyl benzoate were the only compounds with toxicity to both summer eggs and adult females comparable to that of azobenzene. Diphenyl sulphone was more toxic to the egg stage than any of the other compounds tested.

Further details of this and related work will be published elsewhere.

Height of Meson Formation

In an earlier publication[1], it was reported that the intensity of cosmic rays appears to be closely related with the height of the 7·5-cm. mercury pressure-level. It was found that the correlation of cosmic-ray intensity at constant atmospheric pressure with the height of lower pressure-levels is rather low, though gradually increasing with height. When the 7·5-cm. pressure-level is chosen—the highest for which sufficient meteorological data were then available—this correlation reaches the value − 0·67. On the basis of the instability of the meson and by assuming that the bulk of the penetrating component originates at this presure-level, the value 18·6 km. was obtained for the mean range of mesons. In support of this hypothesis is the fact that if we take for the mass 180 m_e and for the average momentum of the mesons along their path down to sea-level the value 2,800 MeV./c. given by Rossi[2], then we have for the rest-life the value $2 \cdot 04 \times 10^{-6}$ sec., which agrees with the one generally accepted.

A study of the results obtained for the effect of ground temperature on cosmic-ray intensity in different parts of the world has now been made. It appears from this study that the mean value of the temperature coefficient α_1 obtained by using variations from day to day is about half the value, α_2, obtained by the use of variations from month to month. In addition to this it is known that α_1 shows a marked seasonal change[4].

Using upper-air data kindly supplied by the Meteorological Office, I have found that the difference between α_1 and α_2, as well as the seasonal change of α_1, for which so far as I know no explanation has been offered, can be accounted for as an effect of meson decay if we assume as before that mesons originate at the 7·5-cm. pressure-level, and take 18·6 km. for the mean range. The twelve-monthly variation in cosmic-ray intensity as obtained by Forbush[5] appears to be fairly well explained also by the same hypothesis.

We might therefore conclude from these results that the bulk of mesons is generated at the 7·5-cm. mercury pressure-level.

To see, however, what the results would be if a higher pressure-level had been assumed for the layer of meson formation, I have taken the 3-cm. pressure-level, the highest for which sufficient meteorological data are now available.

	α_1	α_2	12-monthly variation amplitude
Observed values . . .	−0·10%	−0·18%	1·43%
From 7·5 cm. Hg pressure-level .	−0·10	−0·24	1·65
,, 3·0 ,, ,, ,, .	−0·15	−0·43	2·40

The accompanying table compares the results so obtained with the previous results.

It can be seen that the hypothesis of meson formation at the 3-cm. pressure-level leads to values which are roughly fifty per cent higher than those for the 7·5 cm. mercury pressure-level. To reconcile them with the experimental results, we should clearly have to take for the mean range of mesons a value of 28 km., a fifty per cent increase; but this value, together with the fact that in this case we should have to take for the average momentum of the mesons along their path[6] 2,100 MeV./c., would lead to a rest-life of $4 \cdot 0 \times 10^{-6}$ sec., a 100 per cent increase over the accepted value.

The conclusion appears, therefore, to be that the bulk of mesons is generated at, or little above, the 7·5-cm. pressure-level, at the height of the maximum of the Pfotzer curve for the intensity of the total radiation.

If the average layer for meson formation lies at that height, it follows that the intensity of the meson component should be decreasing at the 3-cm. mercury pressure-level (22 km.). On the other hand, the experimental result of Schein, Jesse and Wollan[7] shows that the hard component increases gradually up to the height of 2 cm. mercury pressure reached in their experiment. The two results, however, are not necessarily mutually exclusive if, as generally supposed, the mesons are formed by primary protons the penetrating power of which is not too different from that of the hard component. The intensity of the primary protons should increase gradually with height.

A complete account of this investigation is being sent to the Physical Society of London.

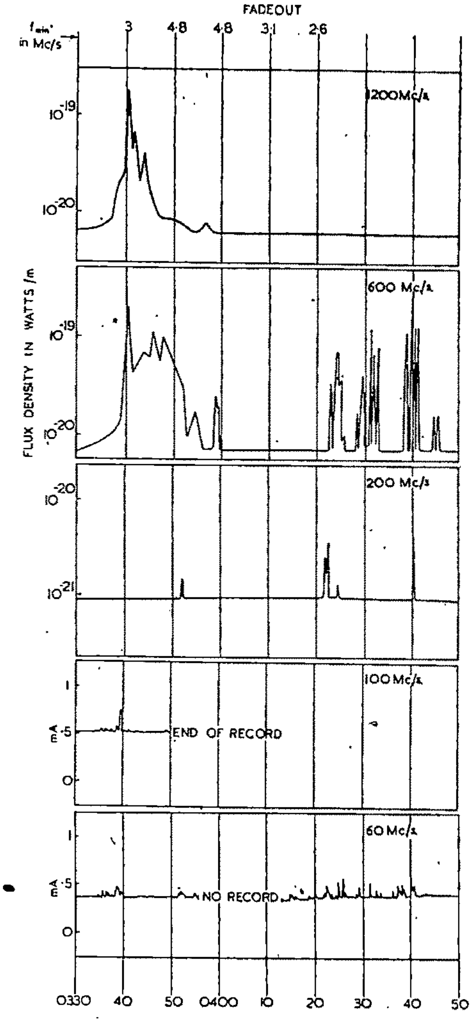
A Solar Noise Outburst at 600 Mc./s. and 1,200 Mc./s.

Simultaneous records of solar radiation at 200 Mc./s., 600 Mc./s. and 1,200 Mc./s. have been made at this laboratory for approximately two hours per day since August 18, 1947. In general, the 200 Mc./s. radiation is similar in character to that described by McCready, Pawsey and Payne-Scott[1], showing a considerable number of short bursts and an increase in general level as some sun-spots cross the meridian. The 600 and 1,200 Mc./s. records, on the other hand, show almost a complete absence of bursts, the level remaining fairly constant for any one day. The radiation received when the sun is almost free from sunspots corresponds to a solar black-body temperature of 0·5 million degrees



Kelvin at 600 Mc./s. and 0·1 million degrees Kelvin at 1,200 Mc./s. and is almost certainly thermal in origin. As sunspots appear, the temperatures rise gradually and show close correlation with sunspot area. The maximum steady levels recorded to date are 1·0 million degrees at 600 Mc./s. and 0·2 million degrees at 1,200 Mc./s. The absence of rapid changes in level suggests that the radiation is still thermal in character, and it is thought that the increase is due to the magnetic field of the sunspots raising parts of the effective radiating shells into the corona[2], which is at a temperature of at least 1 million degrees.

An isolated exception to the above general behaviour occurred on October 4, when there was an outburst of radiation on 600 Mc./s. and 1,200 Mc./s. Both levels increased to thirty times their normal value and remained high for approximately ten minutes, showing the typical characteristics of an outburst. A radio fadeout was reported by the Mount Stromlo ionospheric recording station at the same time. On 600 Mc./s. another disturbed period characterized by a series of bursts began twenty minutes later. The 200 Mc./s. record was that of a quiet sun with only a few isolated bursts. For part of this period records are also available on 60 Mc./s. and 100 Mc./s. On these frequencies no outburst occurred, but a group of bursts coincided with the commencement of the outburst at the higher frequencies. The records are shown in the accompanying figure.

The 200 Mc./s., 600 Mc./s. and 1,200 Mc./s. levels are plotted in terms of flux density. If this were done for the 60 Mc./s. and 100 Mc./s. records, even small bursts would appear as large increases in flux density and a false emphasis of relative solar activity would result. Consequently the records have been left in the arbitrary scale of receiver output current, and indicate in this instance mild solar activity at 60 Mc./s. and 100 Mc./s.

The absence of an outburst on 200 Mc./s. was not due to an instrumental defect, because the aerial was directed away from the sun several times during the period and gave a consistent reduction in receiver output. This indicated that a definite and steady noise contribution was being obtained from the sun.

It is of interest to note that the only other solar disturbance recorded for frequencies above 200 Mc./s. is a 480 Mc./s. storm reported by Reber[3], which also coincided closely with a radio fadeout[4]. In both Reber's case and ours, the occurrence of the fadeout may be taken as fairly certain evidence that a chromospheric flare occurred at the same time. Allen[5] and Appleton and Hey[6], observing at 200 Mc./s. and 64 Mc./s. (4·7 metres) respectively, have noted that some flares are accompanied by solar noise outbursts. As the noise radiation at 600 Mc./s. and 1,200 Mc./s. is believed to arise at lower levels in the sun's atmosphere, a closer correlation between outbursts and flares might be expected on these higher frequencies.

This work is part of the research programme of the Radiophysics Laboratory, Commonwealth Council for Scientific and Industrial Research.

Cosmic Rays and the Magnetic Field of the Moon

IN a recent communication, S. Chapman[1] has calculated, on the basis of the theory of proportionality between magnetic moment and angular momentum developed recently by P. M. S. Blackett[2], that the ratio M_M/M_E between the magnetic dipole moment of the moon and that of the earth is 1/38,400. It may be readily shown that if this result is correct the magnetic field of the moon can only affect particles of primary cosmic radiation of very small energy, which are able to reach the earth only in the immediate vicinity of the geomagnetic poles. In fact, we have[3]

$$M_M/M_E = (D_M/R_E)^2 (r_E/r_M)^2,$$

which on replacing M_M/M_E by Chapman's value, taking for the ratio D_M/R_E (D_M, distance from the earth to the moon; R_E, radius of the earth) its known value, and using for r_M the limiting value $r_M = 0\cdot414$, gives $r_E = 0\cdot05$ millistörmers, or approximately 0·1 MeV. (1 MeV. = 10^6 eV.) if the primary particles are protons, 0·3 MeV. if electrons.

It is therefore clear that the present difficulties[4] concerning the origin of the diurnal and seasonal variations of the intensity of cosmic radiation cannot be traced to a possible magnetic field of the moon of the magnitude predicted by Blackett's theory. It is also obvious from the foregoing discussion that scarcely any measurable effects on cosmic radiation can be expected to arise from the possible existence of such a field.

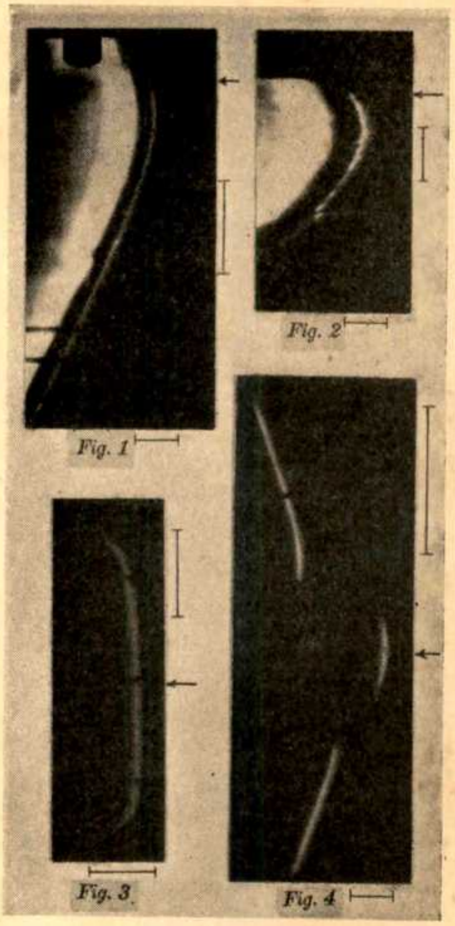
Initiation of High Explosives

IN several communications in *Nature*[1–4], the spread of the detonation wave near the point of initiation has been discussed. During 1943–46, we carried out similar experiments at the University of Saskatchewan (sponsored by the National Research Council of Canada). Since our conclusions differ in several points from those in the above-mentioned letters, it may perhaps be of interest to summarize some of our results[5].

We used a rotating mirror camera with an image speed of 2,000 m./sec., which is twenty times that used by Weibull[1]. With this high speed it is possible to study changes in the detonation waves within much smaller intervals of space and time than has been done by Weibull and others.

Contrary to the results of Weibull[1], and of Mitchell and Paterson[3], we found that in all cases investigated by us the apparent centre of the spherical detonation wave is some distance (initiation distance) *in front of* the detonator. Fig. 1 shows a rotating mirror photograph of the detonation of three cylindrical cyclonite pellets (containing 9 per cent beeswax) of density 1·55 in tandem, initiated by a No. 6 detonator in contact with the centre of (but not embedded in) the top surface. The time axis is horizontal; the detonation proceeds from top to bottom. The explosive was contained in a wide glass tube filled with propane, which served to suppress the shock-wave luminosity. The thin track to the right is the detonation track; the broad and bright track to the left is due to the impact of the shock wave on the glass wall. Fig. 2 gives a similar picture for a pressed T.N.T. pellet of 32 mm. diameter and 22 mm. height, initiated by a No. 8 detonator (as used by Weibull). The important feature of these tracks is the bending back at the top (hook effect), which indicates that the centre of the spherical wave is *below* the top surface in spite of the fact that the initiation occurred at the top surface. It should be emphasized that the same effect was found consistently in many shots of this type, not only for cyclonite and T.N.T., but also for tetryl and NENO[6] (the latter both pressed and cast). The initiation distance is approximately constant for a given explosive in different shots. It varies from about 2 mm. for tetryl to 7 mm. for T.N.T. A positive initiation distance has also been found for liquid explosives (super-cooled NENO, and DINA[6] at about 70° C.) and even for lead azide (the latter initiated in a glass tube by a hot wire above the top surface).



HORIZONTAL LINES UNDER PHOTOGRAPHS INDICATE TIME OF 1 MICROSEC. VERTICAL LINES INDICATE LENGTH OF 1 CM. AT CHARGE; ARROWS INDICATE POINTS OF INITIATION. BLACK LINES THROUGH DETONATION TRACKS ARE IDENTIFICATION MARKS

When the explosive is initiated by a detonator placed near the surface that faces the camera rather than in the centre of the top surface of the cylindrical pellets, no hook effect is observed, in agreement with expectation. Instead, a dark space is observed; that is, for a distance equal to the initiation distance, no detonation luminosity is found.

Further evidence was obtained by the detonation of hemicylindrical charges initiated in the centre of the flat face, the axis of the cylinder being horizontal. If the spherical detonation wave originated at the point of contact of the detonator, it would reach all points along the intersection of a vertical plane with the surface of the cylinder at the same time. Actually, as Fig. 3 shows for cyclonite (density 1·5), the observed traces are not straight but bent back at top and bottom. This is again in agreement with the assumption of an initiation distance.

It appears to us that the interpretation of these results can only be that the detonator sets up a low-order detonation, which, after travelling for a distance, changes over within a rather small region of the wave front to high-order detonation. The low-order detonation described here seems to be of a fundamentally different type from the low-order detonations discussed by Shepherd[2] and by Jones and Mitchell[4] which we have also observed. While in the latter a change to high-order detonation occurs more or less uniformly and simultaneously over the whole wave front, in the former the transformation takes place in a small part of the wave front only, which forms the centre of the high-order spherical detonation wave. Moreover, this new type of low-order detonation appears even for rather strong initiation and never extends over large distances. Only by reducing the strength of the initiation (by interposing sheets of paper between detonator and high explosive) to a point very close to the limit where failure occurs have we been able to increase the length of the initiation distance by a factor of two or three. From our experience it would appear that this type of low-order detonation is a necessary preliminary in each individual initiation process.

In T.N.T. the situation is apparently more complicated, since in a number of photographs we found a slowing down of the high-order detonation, leading either to a fading out, or, at a certain place, to a second speeding up to the final high-order detonation. This second transformation is of the type observed by Shepherd[2] and by Jones and Mitchell[4]. The peculiar behaviour of T.N.T. may be due to the fact that the T.N.T. used in the pellets had a rather large particle size (about 1 mm.).

Very striking results confirming the peculiar behaviour of the new type of low-order detonations were obtained when thin flat pellets of a thickness of a few millimetres (that is, of the order of the initiation distance) were initiated in the centre of one flat face while the other flat face was facing the camera. Fig. 4 shows a photograph obtained with cyclonite. Instead of one single track, there are three apparently unrelated partial tracks. They represent three different high-order detonations produced at different points of one and the same pellet and at slightly different times by one and the same initiation. It appears that the initial low-order detonation changes to high-order at different places and times. In larger charges the first formed detonation wave will soon spread and leave no explosive for the others. But in sufficiently thin charges the different waves can be observed, as in Fig. 4. By putting a steel plate behind the thin pellets, we have checked that the different tracks are not due to different fragments of the detonator.

From the width of the track in Fig. 1 and similar photographs, an upper limit for the duration of the luminosity may be estimated. It is 0·05 microsec. (only a sixth of the limit given by Mitchell and Paterson). In the case of cyclonite it was found from other evidence that the actual value is close to this limit.

Principle of a Counter-streaming Centrifuge for the Separation of Particles of Different Sizes

When a liquid containing suspended particles of uniform density streams through a conical tube, the velocity of the particles is greatest at the apex of the cone and decreases in the direction of the base. If the tube is placed in a centrifuge with the apex pointed away from the centre of rotation, in the direction of which the liquid is made to flow, the particles acquire, in addition to the velocity due to the liquid stream, a velocity in the opposite direction owing to the centrifugal effect. If Z is the distance between the apex and the centre of rotation, R the radius of the cone at the distance L from the apex, V the volume of liquid passing across any section of the tube in unit time, and x the distance from the centre of rotation, then the streaming velocity f over any cross-section of the tube is

$$f = \frac{V}{\pi(R/L^2)\,(Z-x)^2}.$$

The velocity of the particles in the direction away from the centre of rotation, however, increases linearly with the distance from the latter. In a certain cross-section (e) the two velocities are equal for a given particle size. Particles of this size situated centripetally from e are transported in the centrifugal direction and vice versa. Thus, when dynamic equilibrium has been attained, they have been accumulated in a very short section of the tube. Other particles are similarly accumulated in sections characteristic of their sizes; the smaller their radii (r), the nearer the centre of rotation are their planes of equilibrium. The distribution of these planes along the radius of rotation is derived from Stokes' law and the above expression for the streaming velocity:

$$r = \frac{3}{2\pi n} \cdot \sqrt{\frac{\eta \,.\, V}{2\pi(S-S')}} \cdot \frac{1}{\sqrt{X}\,.\,(R/L)\,(Z-x)},$$

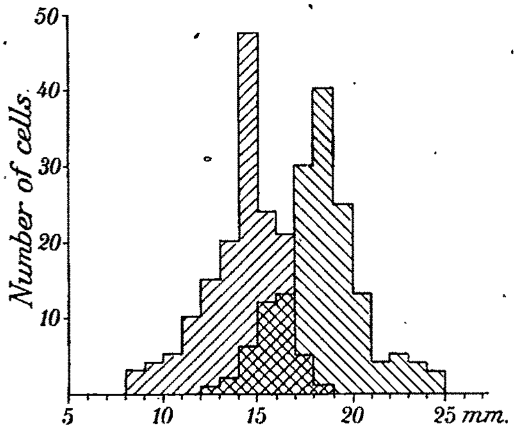
where n is number of revolutions per min., η is viscosity of liquid, S is density of particles, S' is density of suspension medium. For $x = Z/3$, r has a minimum value:

$$r_{\text{min.}} = \frac{3}{2\pi n} \cdot \sqrt{\frac{\eta \,.\, V}{2\pi(S-S')}} \cdot \frac{1}{\frac{2}{3} \cdot \frac{R}{L} Z \sqrt{Z/3}}.$$

This implies that only particles with radii smaller than $r_{\text{min.}}$ can pass with the liquid stream through the tube. This minimum value, characteristic of each tube, is dependent only on R/L (that is, the apical angle of the cone), other things being equal.

As soon, however, as particles accumulate in a centripetal segment of the tube, the centrifugal part of which contains a less dense suspension or pure liquid, the heavier layer breaks up, forming a centrifugally directed current. Also particles with radii smaller than $r_{\text{min.}}$ are carried by this current and caught in a kind of circuit current formed between the chief and the centrifugally directed currents. To avoid interactions between these two currents, that flowing centrifugally is conducted outside the tube through a side channel, the particles being introduced again near the apex and thus made to pass through the separating tube several times. Because of the influence of rotation on the moving liquid and particles, the centripetal part of the tube should be turned towards the direction of rotation. If two tubes with suitable chosen values of R/L are coupled in series so that the tube with a larger $r_{\text{min.}}$ is first passed by the particles, any desired fraction of particles can be removed from the suspension.

In work with large particles having a high density compared to that of the liquid, and a low liquid viscosity, a necessary condition is that the influence of gravity on the particles is eliminated. This can be realized by rotating the centrifuge in the vertical plane.



BAKER'S YEAST CELLS SUSPENDED IN TAP WATER AND CENTRIFUGED FOR 60 MINUTES. ABSCISSA, GREATEST DIAMETER OF THE CELLS (× 2,350). SHADED AREAS SHOW NUMBERS OF LARGER CELLS RETAINED IN THE SEPARATING TUBE AND IN A FOLLOWING TUBE RESPECTIVELY; THE OVERLAPPING WILL DIMINISH ON PROLONGED CENTRIFUGATION

A trial centrifuge has been constructed on these principles and is at present being employed for the fractionation of yeast cells (see graph) and other biological material. A detailed description will shortly be published elsewhere.

Electrokinetic Potential and Surface Structure of Barium Sulphate

WHILE there are many investigations on the influence of electrolytes on the electrokinetic or ζ-potential of solids, very few investigators have considered the relation between the ζ-potential and the structure and composition of the solid itself. This is partly due to the fact that in many systems the potential-determining ions are foreign to the solid.

We are at present investigating the ζ-potential of sparingly soluble ionic solids such as barium sulphate against their saturated solution by the streaming potential method. In this case, the potential-determining ions originate from the solid. Precipitated barium sulphate is unsuitable for investigation, because the validity of the electrokinetic equations is limited to systems in which the diameter of the 'pores' of a plug is greater than the thickness of the electric double layer. We therefore prepared larger crystals (up to 2 mm.)—which could be ground afterwards to any desired size—by recrystallizing barium sulphate from hot concentrated sulphuric acid and subsequent ignition. The following results are typical:

	ζ in mV.
Recrystallized barium sulphate, sample 1	+ 24·2
Recrystallized barium sulphate, sample 3	+ 25·0 ; 24·3
Recrystallized barium sulphate, sample 4	+ 26·6 ; 27·1
Natural barite, sample *B*, ignited	+ 5·4 ; 5·3
Natural barite, sample *C*, ignited	+ 8·4

In spite of the fact that during preparation of recrystallized barium sulphate there was always an excess of sulphate ion, the potential is *positive* and well reproducible within 1 mV. for each sample. The ignition temperature (500–1,000° C.) has no influence on the potential. Most electrolytes change the potential *reversibly* at room temperature; barium salts increase it, sulphates decrease it; but when, after treatment with the electrolyte solution, the potential is then measured against a saturated barium sulphate solution, the original value is always obtained. This value must therefore be regarded as a property of the sample. This behaviour is shown both by recrystallized barium sulphate and natural barite.

There is, however, a striking difference between the high potential of recrystallized barium sulphate and the much lower potential of natural barite. Spectroscopic analysis of our samples revealed that natural barite contains strontium and traces of calcium as impurities. However, these impurities cannot be responsible for the difference in potential. We incorporated such impurities into the recrystallized barium sulphate (during recrystallization); but, as a result, the potential was slightly increased, never decreased. Moreover, when natural barite is recrystallized from sulphuric acid, a high potential (27 mV.) is obtained.

These and similar observations, which will be discussed in more detail elsewhere, lead us to the conclusion that the difference in potential between recrystallized barium sulphate and natural barite is not due to a difference in composition. The most likely cause is a difference in structure (geometrical or otherwise) of the surface. Natural barite, even after crushing, has even crystal surfaces, whereas recrystallized barium sulphate has very irregular surfaces. This is shown by an investigation in an optical as well as in an electron microscope, for the latter of which we are indebted to Dr. A. L. G. Rees and Mr. A. J. Hodge, of the Division of Industrial Chemistry of the Council for Scientific and Industrial Research. It is likely that the field of force is less well balanced in an irregular surface than in an even one.

Bikerman[1] suggested that the ζ-potential of a rough surface should be different from that of a smooth one for purely geometrical reasons. However, the distortion of the field of force in the surface as a factor influencing the electric potential at a surface is a somewhat unfamiliar concept in the field of electrokinetics. Nevertheless, besides our own observations, there are several findings of other investigators[2,3] which suggest that the ζ-potential of a crystalline solid is not solely determined by the composition of the system.

Chemical Effects of Ionizing Radiations

In 1944 it was suggested[1] that the primary net process in the action of penetrating radiations (γ-rays, X-rays, etc.) on the water molecule consists in its splitting in the following way:

$$H_2O \rightarrow OH + H,$$

which presumably takes place by way of the formation of H_2O^+ and H_2O^-. All the known chemical effects in aqueous solutions can be interpreted on this basis[1,2], which furthermore permits an adequate description of the biological effects of radiations[3,4]. Recently, Dainton[5] found that acrylonitrile in dilute aqueous solution on irradiation by X-rays or γ-rays shows polymerization, which he attributed to the action of primarily formed hydroxyl radicals (according to the above scheme) in view of the fact that these radicals are known to initiate polymerizations[6].

We have now succeeded in demonstrating the mode of action of penetrating radiations in aqueous solutions by investigating the reaction products formed by irradiating some simple organic substances such as benzene and benzoic acid in dilute aqueous systems. If hydroxyl radicals are formed primarily, it should be possible to isolate some of the corresponding substances containing OH groups, that is, products of hydroxylation. This, indeed, proved to be the case.

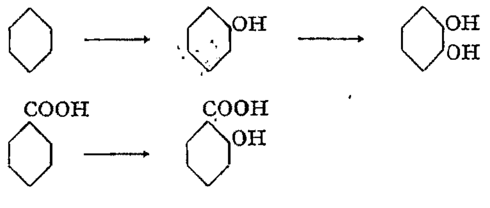
Benzene, suspended in water from which oxygen had been carefully excluded, was irradiated by X-rays by bringing it close to the target of a 200-kV. tube, and a dose of the order of 10^6 r. units was given. This resulted in about 0·1 millimol. of phenol being formed, which was identified as the tribromo derivative. A number of other substances were also found in smaller quantities, among which diphenyl was isolated.

In the irradiation of dilute aqueous solutions of benzoic acid by X-rays, under similar conditions, approximately 0·1 millimol. of hydroxybenzoic acids were formed. Salicylic acid was isolated and was identified by colour reactions and as *p*-nitrobenzene-azo-salicylic acid[7]. (The X-ray irradiations were carried out at the Royal Victoria Infirmary, Newcastle-upon-Tyne; we are indebted to Dr. F. T. Farmer, who made all the quantitative determinations of the X-ray dosage.)

We have also carried out similar experiments using a neutron – γ-ray source (corresponding to 1 gm. of radium mixed with beryllium powder). With this source, benzene gave, in addition to the products mentioned above, catechol and products originating from the opening of the benzene ring. This difference is presumably due to the higher local concentration of radical produced by the recoil protons (from the neutrons).

In all these cases the total yield of the hydroxylated reaction products depends on the *p*H of the solutions.

The above results suggest the following sequence of reactions in the case of benzene and benzoic acid:



In the case of benzene, the intermediate formation of free phenyl radicals is suggested by the appearance of small amounts of diphenyl among the reaction products. The dehydrogenation to the phenyl radical may be due to a reaction with the hydroxyl radical or possibly with hydrogen atoms. Experiments to decide this are in progress.

The results indicate that: (i) Hydroxyl radicals are formed by the action of radiations on aqueous systems, since the reaction products found are the same as those obtained by the action of hydroxyl radicals produced chemically (for example, by the system $H_2O_2 - Fe^{II}$ salt). (ii) The oxidation products are very similar to those obtained in the biological oxidation of these substances, which suggests that hydroxyl radicals may play an important part in certain biological oxidations[8].

We are indebted to Prof. F. A. Paneth for permission to carry out the neutron experiments in the Londonderry Laboratory for Radiochemistry at Durham.

A full account of this work will be published elsewhere.

A Coefficient of Viscous Extension

While working on a generalized theory on straining of amorphous or quasi-amorphous solids, it became clear that one could include the straining of viscous fluids by means of a suitable stress-strain parameter λ which I call a 'coefficient of viscous extension' related to the 'coefficient of viscous shear' usually called[1] the coefficient of viscosity μ. In this communication only the flow strain component of a deformed substance[2] is considered, so that the elastic and plastic components[3] are neglected and, further, only isotropic substances are discussed.

An infinitesimal angle γ_{ij} of shear 'slide' has twice the arithmetical value of the normal strain e_{ij} in the 'auxiliary' plane at 45° to the planes on which the shear stress S_{ij} operates[3,4]. Hence, differentiating with respect to time t and using the coefficient of viscosity gives

$$2\frac{\partial e_{ij}}{\partial t} = \frac{\partial \gamma_{ij}}{\partial t} = \frac{S_{ij}}{\mu}. \qquad (1)$$

But the normal strain e_{ij} due to shear can be regarded as due to the 'partial' strains ε_{ij}, ε_{ji} and transverse contraction ratio q[5,1,2,3]. But the partial strain ε_{ji} is equal to but of opposite sign to ε_{ij}, so that

$$e_{ij} = (1+q)\varepsilon_{ij}. \qquad (2)$$

The normal stress T_{ij} is 'auxiliary' to, and of the same arithmetical value as, the shear stress S_{ij} if the displacements are to be single-valued[2]. Hence, if we *define*

$$T_{ij} = \lambda \frac{\partial \varepsilon_{ij}}{\partial t}, \qquad (3)$$

then from (1), (2), (3)

$$\lambda = 2(1 + q)\mu. \qquad (4)$$

This 'coefficient of viscous extension' allows one to synthesize the Navier–Stokes viscous fluid theory with a theory on the straining of solids. The coefficient λ in the flow case is analogous to Young's modulus in the static strain case. However, it should be noted that in (1) and (3) only *time-rates of straining* occur, so that my theory on strains of any magnitude can be used to give a general theory on straining that incorporates flow in solids and viscous fluids. As presented here, the coefficient of viscous extension λ is a non-constant tangent modulus if the substance is quasi-viscous[6]. The transverse contraction ratio q will have the value $\frac{1}{2}$ in solids as well as liquids if volume changes do not occur. However, caution is necessary in view of the static 'plastic' transverse contraction ratio value 0·36 for duralumin[7] found by me; this has been checked with a photo-grid and a specially designed optical extensometer[8]. Further, the same value was found for changes in thickness of the tensile specimen.

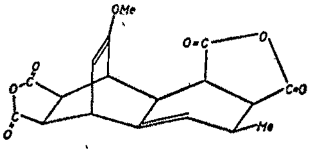
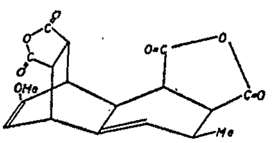
Addition of Maleic Anhydride to Anethole

ONE of us[1] has earlier obtained a small amount of a crystalline compound (m.p. 241°, decomp.) of anethole with two moles of maleic anhydride, the main bulk of the reaction product being a heteropolymer[1,2,3]. We found that, if a small amount of dimethylaniline is added, the formation of the heteropolymer product is prevented and the yield of the crystalline adduct was as high as 60 per cent. We have confirmed the structure previously proposed[1] and our work led further to the determination of the steric configuration of the compound.

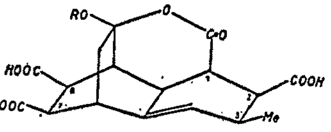
If we assume an endo-*cis* type addition[4] and start from anethole, which may be supposed to be a *trans* anethole, then the formation of four possible stereoisomers (that is, two racemates) could be expected, namely, I, II and their respective antipodes. The properties of our compound agree with those expected from I.



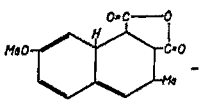
I.



II.



a...R=Me III. b...R=H



IV.

The following reactions may be cited in favour of I and excluding II. Mild alkaline hydrolysis leads to III (*a*); if the hydrolysis is more energetic, III (*b*) is obtained. The ultra-violet absorption spectrum of III (*b*) does not show the characteristic band of a carbonyl group. This acid forms heterocyclic compounds with hydroxylamine as well as with phenylhydrazine; hence one of the carboxyl groups participates also in the condensation. When III (*b*) was boiled with 5 *N* hydrochloric acid, the carboxyl groups in positions 1 and 8 became a *trans* position and an isomeric *trans* keto-acid was obtained containing a free carbonyl group, the presence of which was revealed by the ready formation of a regular oxime and by its absorption spectrum. The olefinic bond of III (*b*), which is resistant to catalytic hydrogenation, was confirmed by the addition of two hydroxyl groups. If compound I is heated with sulphur to 300°, it decomposes with formation of maleic anhydride and the anhydride of 3-methyl-7-methoxy-naphthalene-1 : 2-dicarboxylic acid.

The formation of the compound I makes it clear that, from the point of view of diene synthesis, anethole behaves as a conjugated tetraene, that is, it gives first with one mole of maleic anhydride the labile primary compound IV, which in turn reacts instantaneously with another mole of maleic anhydride, forming the stable end-product I.

Our observation seems to be of interest from the following two points of view: (1) So far as we know, this is the first *proved* example of the possibility of disturbing the aromatic character of a mononuclear system through a Diels–Alder reaction. Such a process leading to a compound of analogous structure to I had been suggested but later rejected by Wagner-Jauregg[5] in the case of the Diels – Alder reaction of *as.* diphenylethylene. This structure has, however, recently been accepted by Bergmann and co-workers[6], but was not established by them in a decisive manner. (2) From our results it is probable that the Diels – Alder reaction of some styrene derivatives is initiated by the heteropolar resonance form of the partners[7].

The full details of these investigations will be published elsewhere.

OSCILLOGRAPHIC ANALYSIS OF THE NON-ACOUSTIC FUNCTIONS OF THE VERTEBRATE EAR

By Dr. OTTO LOWENSTEIN
Department of Zoology, University of Glasgow

THE non-acoustic functions of the vertebrate ear are localized in the semi-circular canals with their ampullary end organs, and the utriculus, the anterior or uppermost of the two or three otolith organs of the vestibulum[1]. The function of the semi-circular canals is restricted to the perception of angular accelerations occurring during rotational movements, chiefly at their onset and cessation. The utriculus, on the other hand, is held responsible for the perception of changes in position within the gravitational field, of linear accelerations brought about by straight-line movements, and of the centrifugal effect during relatively fast rotations.

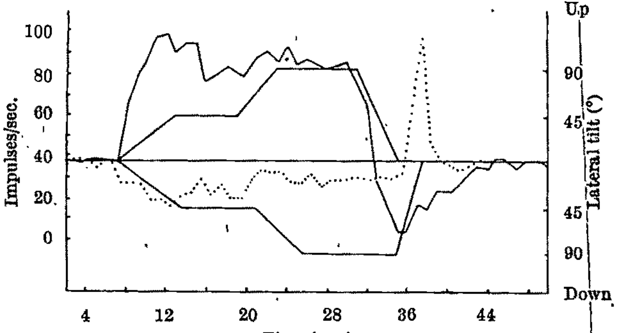
Until recently, analysis of the equilibrium function of the labyrinth was based entirely on evidence obtained by elimination experiments in which operative removal of the organ as a whole or in parts or transection of the various branches of the eighth nerve was followed, in the surviving animal, by observation of the equilibrium reflexes of head, eyes, or limbs, and their comparison with the normal labyrinthine reflexes. With the development of Adrian's technique of oscillographic recording of the electrical activity of sense organs arose the possibility of the direct analysis of the equilibrium function of the labyrinth. The first attempts in this field were reported by Ashcroft and Hallpike[2], and Ross[3] on the frog, and by Lowenstein and Sand[4] on the dogfish. Thanks to the ideal conditions offered by the cartilagenous nature of the elasmobranch cranium, it was found possible in the intact dogfish to record directly from the nerve-branch supplying the ampulla of the horizontal semi-circular canal. This led to the discovery that the intrinsic mechanism of canal function is based upon a background of resting discharge the frequency of which is, in the horizontal canal, increased by homolateral, and decreased by contralateral angular acceleration in the plane of the canal, with corresponding post-rotatory after-effects in response to deceleration. This mechanism clearly provides the means by which a single ampullary rotation-receptor unit can signal to the centre opposite phases of angular acceleration and deceleration in a given plane. The corresponding ampullæ on both sides of the head work antagonistically, and the reflex responses in the intact animal depend on the balance of the afferent discharges from left and right labyrinths.

Apart from serving as a background for this two-directional response, the resting discharge was also claimed to provide a continuous source of tonus supply to the musculature; and this could afterwards be demonstrated by means of elimination experiments carried out on the horizontal canal of the pike[5]. The analysis of the function of the ampullary end-organs in the two vertical canals which proved impracticable in the intact animal was carried out on the surviving preparation of the labyrinth in the isolated cranium of the ray[6]. As a result, a complete picture of the integrated action of all six semi-circular canals during rotation about the three primary axes was obtained, which could be correlated with the known eye muscle reflexes normally evoked by these rotations. In contrast to the horizontal canals, which respond to angular accelerations in or near their plane only, each vertical canal responds to rotation about all three primary axes. They are laterally synergic on rotation about the longitudinal axis, transversely synergic on rotation about the transverse axis, and react with reduced sensitivity to rotations about the vertical axis, when they are found to be diagonally synergic. An analysis of the integrated activity of the six semi-circular canals in relation to the known eye muscle reflexes evoked by rotational stimuli yielded a consistent picture, which furnished evidence for the vestibular origin of the simultaneous contraction of pairs of antagonistic eye muscles, occurring during labyrinthine eye nystagmus. These have been recorded myographically in the rabbit by Lorente de Nó[7], who described them as pivoting reactions, postulating their central nervous origin.

In a consequent quantitative study of the mechanism of canal function carried out on the horizontal semi-circular canal of the isolated labyrinth of the ray[8], single-fibre discharges were recorded in response to different intensities of angular acceleration and during rotations at constant angular velocities. During uniform angular acceleration the impulse frequency increases and decreases in a linear manner proportional to the acceleration and deceleration. The threshold acceleration was found to be as low as 3°/sec./sec., a fact which suggests that high turntable speeds often used in equilibrium experiments and in clinical tests may involve angular accelerations representing considerable overstimulation of the sense organ. During prolonged rotation at constant speed, the frequency of discharge, after reaching a maximum or minimum during the initial acceleration, gradually returns to the value of the resting discharge. It is interesting to note that the maximum time of 20–30 sec. taken for this return is the same as that described by Steinhausen[9] in his experiments on the physical properties of the living cupula terminalis of the semi-circular canals in the pike. It also agrees with the duration of post-rotatory after-effects, for example, nystagmus and vertigo, observed in all vertebrates, including man. Results on the human subject obtained by Jonkees and Groen (Utrecht), according to private intimation by the authors, also bear out this fundamental similarity in time relations. All this fully justifies the interpretation of reflexes to angular acceleration in terms of the elastic properties of the cupula, and makes unnecessary the assumption of their central elaboration.

The analysis of the mode of function of the vestibular receptor for gravitational stimuli and linear accelerations, namely, the otolith organ in the recessus utriculi, had been held up by the War, but has now been attempted in collaboration with my colleague, Mr. T. D. M. Roberts. The work was carried out at the laboratory of the Marine Biological Association at Plymouth during the summer of 1947, with the aid of a Royal Society grant from the Parliamentary Grant-in-aid of Scientific Investigations, and with the privilege of the use of the British Association Table at the Plymouth Laboratory. The results to be reviewed in this communication will be the subject of a fully documented publication elsewhere.

The method used was similar to that described in the publications on the function of the semi-circular canals. Considerable technical difficulties had, however, to be overcome in the attempt to record from



Horizontal line across graph indicates basic discharge level

RESPONSES TO LATERAL TILT FROM A 2–3 FIBRE PREPARATION FROM THE UTRICULUS OF THE ISOLATED LABYRINTH OF THE RAY. THE STRAIGHT LINES TRACE THE COURSE AND TIME RELATION OF LATERAL UP AND DOWN DISPLACEMENTS FROM THE NORMAL. THE CURVES SHOW THE COURSE OF THE RESPONSE IN IMPULSES PER SEC. AS DESCRIBED IN THE TEXT. ——— RESPONSE TO UPWARDS TILT, ... RESPONSE TO DOWNWARDS TILT. THE PREPARATION SHOWED A BASIC DISCHARGE FREQUENCY OF 38 IMPULSES/SEC. WHEN AT REST IN THE NORMAL POSITION

the branch of the eighth nerve supplying the macula utriculi. In a ray of a wing span of more than twenty inches this is only 5–6 mm. long, measured from its origin at the brain to the final terminations of its fibres in the macula, and of this about 2 mm. only were suitable for electrical pick-up. By carefully peeling off minute strands from the nerve fan on the lateral wall of the utriculus, preparations were made from which analysable records could be obtained of the activity of single sense endings or of groups of small numbers of independently firing units.

Again, as in the case of the semi-circular canal, it was found that, when at rest in the normal orientation in space, the sense endings in the macula utriculi fire off a continuous stream of low-frequency impulses, between 6 and 12 per sec. at 20° C. The frequency level of this discharge remains constant unless the spatial position of the preparation is changed. This could be achieved by slowly rotating the preparation and electrode system fixed in a holder about axes corresponding to the transverse and longitudinal body axes. By means of a clamping device, the preparation could be held stationary in any desired position in space. The accompanying figure shows the result of tilting a two to three unit preparation around the longitudinal axis to positions of 45° and 90° lateral tilt homolateral side upwards and downwards. It will be seen that during the rotation into the new position the discharge frequency changes, increasing during upwards and decreasing during downwards tilt. After the preparation becomes stationary in the 45° and 90° positions a certain return of the discharge frequency towards the level characteristic for the normal position occurs; but after a few seconds the frequency becomes stabilized significantly above or below the 'normal' level. During the return movement a drastic change in the discharge frequency takes place in a sense opposite to that brought about by the initial displacement from the normal. Back in the normal position the discharge returns to the original frequency level. If the same preparation is now rotated about the transverse axis to positions 45° and 90° nose up or down it is found to respond with equal sensitivity to this displacement. The preparation from which the curves shown in the diagram were derived yielded similar responses on rotation about the transverse axis, with an increased frequency level in nose up, and a decrease in frequency in nose down positions, and correspondingly similar behaviour during the rotation to and from the out-of-level positions.

Responses from preparations that yielded analysable records can be classified into four groups, namely, showing increased discharge (*a*) on side up and nose up, (*b*) on side up and nose down, (*c*) on side down and nose down, (*d*) on side down and nose up, while correspondingly reversed displacements bring about a decrease in the discharge frequency. We have not found preparations without a resting discharge or preparations which were capable of responding by either increase or decrease only. We also failed to find preparations which were confined to responding to displacements about either the longitudinal or transverse axis only; and the fact that the two-axis response with its diagonal plane of maximum sensitivity could be demonstrated in a single-unit preparation counters the suspicion that in few-fibre preparations this might have been due to recruitment from two different types of receptors, an assumption which could not be completely refuted on any other grounds.

The present results are based on the evidence from twelve successful preparations with the following numerical distribution of types: Type *a* : 2; *b* : 2; *c* : 1; *d* : 1; of the remaining six preparations, in which for technical reasons the response to displacement about the longitudinal axis could not be recorded, two showed an increase of discharge on nose up, and four on nose down displacement. As all these preparations were obtained from a relatively restricted area of the utricular macula, the conclusion appears unavoidable that the four types of sense endings are dispersed over the whole macula. Their typical mode of reaction will, in this case, have to be ascribed to their minute distribution in or around deformable structures intervening between macula and otolith membrane. We hope that a study of the microscopic pattern of the macula which we are about to carry out will throw further light on this question.

Experiments in which utriculus preparations were subjected to linear accelerations showed repeatable responses of fairly low threshold to straight-line movements in all three planes of space. This result is of special interest in view of the fact that no reliable reflex responses to linear accelerations have so far been detected in fishes[10].

It can thus be stated that the otolith organ of the utriculus is sensitive to positional changes about any horizontal axis, longitudinal, transverse and intermediary. In contrast to the semi-circular canals which respond to angular accelerations only, the otolith organ responds during tilting to angular accelerations and to rotation with constant speed; furthermore, it shows lasting responses to prolonged out-of-level positions. Its ready response to linear acceleration during straight-line translation makes it a certainty that it will also respond to centrifugal effects. The localization of all these functions in the utriculus adds further weighty evidence in favour of the contention that, contrary to the classical theory[11], the utriculus may well be the only otolith organ concerned with the maintenance of equilibrium. Its fundamental sensory mechanism recalls that found in the semi-circular canals, in so far as the responses appear against a background of a steady basic discharge activity which can be modulated in opposite directions.

So far as I am aware, gravity responses to positional changes have only twice before been studied by the oscillographic method. Recording from filaments selected at random from the cranial stumps of the anterior and posterior rami of the eighth nerve of the frog, Ross[3] described gravity responses from the anterior ramus which were presumed to be derived from the utriculus and generally reacted to one only of two opposite directions of tilting in the 'maximally stimulating' plane. The reaction obtained from the posterior ramus also included typical gravity responses, the accurate localization of which was, however, impossible.

Single-unit discharges from the vestibular nucleus of the brain-stem of the cat were recorded by Adrian[12], who was able to distinguish between gravity-controlled and rotation-controlled responses. The gravity receptors were increasingly stimulated during displacement from the normal. In the level position a low-frequency resting discharge was sometimes found which could be abolished by tilting in one direction and increased by tilting in the opposite direction. Response to lateral tilt and to fore-and-aft tilting was found to be separately localized in the vestibular nucleus, but Adrian points out in the discussion of his results that this does not necessarily imply their localization in two different otolith organs.

A discussion of these findings in comparison with the evidence reported in the present communication will be appended to the forthcoming full account of the work.

POWER AND PERSONAL LEADERSHIP

THE Thomas W. Salmon Memorial Lectures, given in previous years by psychiatrists, were delivered at the New York Academy of Medicine last November by Prof. H. D. Lasswell, a social scientist known mainly for his studies of propaganda and his application of psychoanalytic concepts to problems of political science. His topic was "The Dynamics of Power and Personality". "The long-run aim of societies aspiring towards human freedom," said Prof. Lasswell, "is to get rid of power and to bring into existence a free-man's commonwealth in which coercion is neither threatened, applied nor desired. This is the thread of anarchist idealism that appears in all uncompromising applications of the key conception of human dignity." But the more accessible goal, to which Prof. Lasswell gave his main attention, is to secure a democracy in which power is shared as widely as possible and is subordinated to respect for the dignity of the human personality. He therefore discussed the types of people who in our society seek for power and provide leadership. He saw them as drawn very largely from the middle class, as a result not of economic accident but of the psychological characteristics of the class, in particular its tradition of sacrificing immediate gratifications to the acquisition of skills which will ultimately bring a larger reward. "We know that middle-class homes are hothouses of ambition, holding their children to high standards of achievement, and providing the tension between indulgence and deprivation so congenial to the accentuation of power [as a goal]." Within the middle class, professional families contribute a disproportionately large number of leaders, partly because their tradition of public service deters them from seeking purely private advantage in business life. Prof. Lasswell seemed to imply that political leaders' ideals of public service are largely rationalizations of narrower personal needs for power.

It was the less admirable types of power-holder to whom Prof. Lasswell gave most attention. He distinguished the compulsive (or obsessional) type, often bureaucratic in inclination; the dramatizing type, highly concerned with the emotional response he can elicit from others, and characteristically producing the agitator; and the detached type, whose own emotional response is largely screened from his consciousness, and who may supply "useful judges, arbitrators, conciliators, diplomatic negotiators and scientists", but in whom "the absence of lively emotional states can lead to calm, pitiless, destructive conduct". Apropos the obsessional bureaucrat, Prof. Lasswell developed the interesting suggestion that he harbours strong unconscious hostility to the authority of the system he is serving, and by excessive scruples and doubts in interpreting detailed rules he forces his superiors to take responsibility which they had intended to delegate, and so undermines the authority that he means most scrupulously to obey.

Prof. Lasswell pointed out that to understand the destructive form of power seen in war we must attend not only to war itself but also to manifestations of power found everywhere in our social structure; and he suggested that "concentrations of destructive impulse" occur as a result of competitive practices that we take for granted in commerce, industry and public life. "It is impossible to abolish acute destructiveness without altering the equilibrium of the entire social process, since such acute disturbances mainly give vent to stress that has accumulated through the social system as a whole." Hence he advocated a "social psychiatry", one function of which would be to study the tensions created by "the struggle to express native impulses in ways forbidden by authority", the sexual impulse providing one example. For the rest, his prescription against war was "Physical Defence, Psychological Offence", and he urged the opponents of Marxism to emulate the Marxists' effectiveness in political education and propaganda, especially in giving the public as clear a conception as possible of the goal of national policies.

THE FOURTH SOUTH AMERICAN CHEMICAL CONGRESS

THE Fourth South American Chemical Congress was held in Santiago, Chile, during March 1–7, with more than four hundred delegates attending from all the South American republics. Invitations to attend were also extended to a number of countries outside South America: Great Britain was represented by Prof. J. W. Cook, Prof. E. C. Dodds and Dr. F. N. Woodward, the United States of America by Dr. Alfred Gauger, Sweden by Prof. The. Svedberg and Republican Spain by Dr. Francisco Giral.

At the inaugural session in the Law School of the University of Chile, where most of the sessions were held, the delegates and representatives were welcomed by Don Enrique Molina, the Minister for Education, and Don Juvenal Hernández, rector of the University; Dr. Felipe Justo, president of the Chemical Society of Argentina, replied on behalf of the delegates.

In his speech formally opening the Congress, Dr. Edouardo Cruz-Coke, professor of biochemistry in the University of Chile and president of the executive committee of the Congress, stated that this Congress was the largest yet held in South America and was planned to cover a wider field of chemistry than was possible at the Third Congress held at Rio de Janeiro in 1940. He indicated the executive committee's particular pleasure at the presence of so many representatives of non-South American countries, and later accepted on behalf of the committee a letter of greetings from the president of the Chemical Society brought from London by Prof. Cook and a copy of the fellows' register presented by Prof. Dodds on behalf of the Royal Society.

The Congress, which was particularly well organised, due largely to the efforts of Prof. Cruz-Coke, the two secretaries, Prof. Jorge Mardones and Prof. Hermann Schmidt-Hebbel, and their associates on the executive committee, was divided into thirteen sections. These covered the fields of physical and electro-chemistry, inorganic and geochemistry, organic chemistry, biochemistry, chemistry in relation to medicine and toxicology, nutritional chemistry, chemistry in relation to agriculture and applied botany, industrial inorganic and organic chemistry, metallurgy, fuels, chemical engineering and chemical education. During the course of the week, some four hundred papers were read, abstracts of which were made available to delegates in the form of a well-prepared 131-page printed booklet before the opening of the Congress. In addition to these, there were also eight 'Conferencia', two of which were given by British representatives. On March 3 Prof. Cook read a paper on "The Chemical and Biochemical Oxidation of the Aromatic Polynuclear Hydrocarbons", and on the following day Prof. Dodds lectured on "The Proteins as Biochemically Active Substances".

During the course of the week, the British representatives, who were very hospitably received, were given an opportunity of visiting many of the Chilean chemical and medical schools, museums and industrial organisations. The tour around the impressively equipped and staffed Hospital del Salvador was made in the company of Profs. Alessandri and De Amesti, who have been largely responsible for making this one of the most modern and efficient hospitals in South America, comparing favourably with the best European and North American hospitals.

The work of Profs. Edouardo Cruz-Coke and Hector Croxatto and their colleagues at the Medical Schools of the University of Chile and the Catholic University respectively on a wide variety of subjects, including the cardiac stimulants, the biochemistry f the hormones and vitamins, biological oxidations, organic iodo compounds, antibiotics, etc., was found to be both academic and developmental in outlook and conception. The science schools of the Chilean universities, unlike those in Britain and the United States, rely on outside sources for much of their income, and the teachers and students of these two chools consequently associate themselves closely ith certain industrial organisations, and particularly ith the Instituto Médico Técnico "Sanitas" S.A., a company producing a wide variety of organic chemicals including penicillin, organic arsenicals, D.D.T., and the more common pharmaceuticals. The Government-sponsored Instituto Bacteriologico operates in a similar field, and like Sanitas has modern and well-equipped factories and laboratories, and a well-informed and research-minded staff.

For the final sessions, the delegates were taken by road and special train to Valparaiso, where they were first entertained by the directors of the Nitrate Corporation at an impressive alfresco luncheon in the beautiful Parque de Salitre under conditions reminiscent, as one distinguished delegate observed, of Europe before the First World War. In the afternoon, the delegates were shown round the Santa Maria Technical University, where the formal closing session was held later.

The week's activities were rounded off at a colourful reception at the Vergara Palace, in the hills behind Vina del Mar, the beautiful and world-famous South Pacific health resort.

SCIENCE MASTERS' ASSOCIATION (SCOTTISH BRANCH)

THE first annual general meeting of the Scottish Branch of the Science Masters' Association took the form of a three-day meeting in the University of Glasgow during April 1–3, under the presidency of Sir Hector Hetherington, principal of the University. The meeting was attended by about 250 members of the Branch, and there were many visitors. The close and active co-operation of the staffs of the various departments of the University resulted in many exhibitions and demonstrations being available.

During the first day the Department of Chemistry staged exhibitions of the first-year practical course, new apparatus for esterification and distillation, fluorescence spectroscopy and photochemistry. Specimens of rare chemicals were also on view. The Department of Natural Philosophy had much to show in connexion with research in nuclear physics. Cloud-chamber experiments were demonstrated, a large magnet was seen in course of erection for cosmic ray studies, and various artificial radioactive isotopes were produced by neutron bombardment. Great interest was shown in the new 30-million volt synchrotron, under construction by Messrs. Metropolitan-Vickers, and the million-volt proton accelerator attracted many visitors. Prof. W. M. Smart, of the Department of Astronomy, arranged for the Observatory to be open for inspection during the afternoon, while in the Zoology Department the magnificent museum was open to members, and new biology films were shown. The Botany Department contributed a series of demonstrations in plant physiology, antibiotics (penicillin and streptomycin) and products manufactured from marine algæ. New methods of preserving biological specimens in transparent plastics were also shown.

The afternoon of the second day was set apart for visits to well-known Scottish firms specializing in the manufacture of special steels, coal-cutting machinery, nautical instruments, optical instruments, sulphuric acid and in shipbuilding.

One feature of the meeting was the exhibition of apparatus designed and constructed by members, and there was a special exhibit showing surplus apparatus available at very low prices to schools through the Ministry of Supply and the Scottish Education Department. In cases where service apparatus could not be used in schools without adaptation, methods of doing this were demonstrated.

Mr. F. A. Meier, of the London Institute of Education, gave two lecture-demonstrations on the construction and use of scientific apparatus, and lectures were given by Prof. J. W. Cook, on "The Effects of Some Chemical Compounds on the Growth of Cells", by Prof. P. I. Dee, on "The Elementary Particles of Matter", and by Dr. H. F. Steedman, on "Practical Methods in Zoology".

At a discussion on "School and University Teaching", the chair was taken by Sir Hector Hetherington, and leading parts were taken by Prof. J. Walton, Prof. W. M. Smart and Mr. F. G. Daldy, of Trinity College, Glenalmond. Many other members of the Association joined in the discussion, and in response to suggestions put forward steps have been taken to promote a closer liaison between Scottish members of the Science Masters' Association and the faculties of science in the Scottish universities.

At the annual business meeting, Mr. H. S. Sowrey, Glasgow Academy, was elected chairman of the Branch in succession to Mr. W. J. Lodge, Fettes College. The joint secretaries are F. G. Daldy, Trinity College, Glenalmond, and J. Wallace, Melville College, Edinburgh, and the treasurer is W. P. D. Wightman, Edinburgh Academy.

A 150-TON UNIVERSAL STRUCTURE TESTING MACHINE

W. AND T. AVERY, LTD., of Birmingham have recently designed and built a 150-ton universal structure testing machine for Short Bros. and Harland, Ltd. (*Engineer*, December 26, pp. 594–596).

It is significant that it is no longer considered sufficient to carry out tests on the material from which a complicated structure is made, and to base design upon calculations made from the results of such tests alone. There is a growing need to apply as near full-scale tests as possible. Geometrical similarity in test-pieces tested under laboratory conditions show a dimensional effect which it is often difficult to explain, except by assuming an anisotropy or inhomogeneity of the material. It is still more difficult to predict the behaviour of a material under complicated stress distributions from the results of the standard mechanical tests carried out on carefully prepared samples of shapes designed to make the interpretation of the results as simple as possible.

The new Avery machine can accommodate specimens up to 9 ft. 9 in. long in tension and 15 ft. in compression, while it can also be adapted for carrying out transverse tests on specimens up to 7 ft. span.

The tension and compression units are separate. They are, in fact, two testing machines but having a common hydraulic oil pump for applying loads and a dynamometer and indicator cabinet which can be used with either. The advantages to be gained by the separate units are that the effective height is greater, so that longer specimens may be used; and although the two units cannot be used simultaneously, setting-up can proceed in one while testing goes on in the other. This is an important consideration when it is desired to attach the large number of strain gauges often required for the full interpretation of complicated sections or built-up structures. Against the separation of the testing units must be set one disadvantage, namely, the far greater space occupied by the whole machine.

The method of operation and load-recording is similar to previous machines made by Avery's and to other machines of this type. There are four load-ranges: 0–150 tons in increments of 0·5 ton being the highest and 0–15 tons in increments of 0·05 ton the lowest. It is doubtful whether a machine of this capacity can, in fact, be used with any degree of accuracy on the lower range, and it would appear to be preferable to omit this range entirely and to use the machine for the purpose for which it was designed and for which it is eminently suitable.

C. F. TIPPER

GROWTH-PROMOTING SUBSTANCES IN HORTICULTURE

A CONCISE review by Dr. T. Swarbrick of recent developments in the application of growth-promoting substances in horticulture, with special reference to the researches carried out at Long Ashton since 1939, appears in Occasional Publications on Scientific Horticulture No. 5 (published by the Horticultural Education Association, c/o Gibbs and Sons, 16 Orange Street, Canterbury, Kent). Present applications include the acceleration of rooting in cuttings, the prevention of pre-harvest drop in apples and pears, the induction of parthenocarpic development in tomato and other plants, and finally their employment as selective weed killers.

Parthenocarpic fruits of apple and pear have been obtained with certain varieties but not with others, employing 2-4 dichloro-phenoxy-acetic acid, 2-6 dichloro-phenoxy-acetic acid and also beta-naphthoxy-acetic acid. In all cases, however, the artificially 'set' fruit grew slowly and never attained normal size. Similar development was induced in Miller's seedling apple and Conference pear following frost damage to the 'set' fruit during the spring of 1945. Beta-naphthoxy-acetic acid has also proved effective in inducing a very marked increase in 'set' and yiel of the self-sterile varieties of strawberry, Tardive d Leopold and Oberschlesien.

Two interesting lines of investigation are suggeste by the fact that crude extracts of the flowers hav been found to induce parthenocarpic developmen in tomato, and secondly, that stilbœstrol, a syntheti œstrogen of high potency in animals, is similarly effective. Certain of these growth substances, when use at concentrations higher than that required to induc parthenocarpy, produce modification of leaf shape an venation and clearing of the veins closely simulatin many characteristic symptoms of virus infectio This raises interesting conjectures concerning th nature of the action of virus on host. The effect o tri-iodo-benzoic acid in modifying lateral and terminal vegetative shoots of tomato to form flow trusses constitutes an interesting parallel to th suspected action of naturally occurring hormon which are believed to initiate the formation of flow primordia.

The progress already achieved in this field sugges that a joint attack by biochemist and plant physi logist may be expected to lead to a rapid expansi in our knowledge of the biochemical control development and reproduction in plants.

FORAGE RESOURCES OF LATIN AMERICA

BULLETIN 37 of the Imperial Bureau of Pasture and Forage Crops, Aberystwyth, has been prepared by Hugo W. Alberts, in association with the Technical Collaboration Branch, Office of Foreign Agricultural Relations, United States Department of Agriculture. It has been issued by the Imperial Agricultural Bureaux (Pp. 24. 2*s.* 6*d.*).

Grazing and browsing, as it is best known to the forester, of domestic or semi-domestic animals has become an increasingly intensified problem in the modern world. The present monograph gives information in some detail on the position in Peru and their forage resources. The author divides the country roughly into three geographic regions, the coastal region, the sierra and the oriente or montana. The latter, situated to the east of the Andes, consists mainly of tropical forest, the grazing and pasture question having little importance. Since remote times, the Andean Indians of Peru have grazed llamas and alpacas, native to the grasslands of the sierra. These animals had been domesticated and raised for their meat and hides by the time the Spaniards arrived. The llamas were used also as pack animals. On account of the nature of the grasses in many of the mountain valleys, there was always some grazing even in the driest times, because there were two general types of forage, consisting of short grasses, fairly high in palatability, and tall grasses, of lower food value. The tall grasses were not eaten during the rainy season when there was plenty of the short grass available, and consequently the former formed a reserve for the winter months and periods of drought.

Along the coast, forage is produced chiefly to feed dairy cattle. In the sierra, native range grasses supply forage for sheep, llamas, alpacas and some beef and dairy animals. The kinds of forage grown along the coast are principally alfalfa and para grass, supplemented by maize, which is cut and fed in the green state. The native range lands of the sierra produce various species of grasses, which may be classified into two general groups, namely, tall grasses and short grasses, already alluded to. Tropical rain forest species of grasses comprise the principal forage in the oriente.

Some of the pasture lands in different regions are irrigated. The number of animals which can be grazed on areas of from two to three hectares varies considerably, and probably requires a further close study.

EARTHQUAKES DURING JULY–AUGUST, 1947

TWELVE large earthquakes and a score of smaller ones were recorded by the world's seismographs during July, and nine large shocks with numerous smaller ones during August. Provisional epicentres for the large earthquakes have been determined by the U.S. Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association.

The largest earthquakes of the two-monthly period were those of July 29 and August 5. That of July 29 occurred on the borders of Tibet and Burma, and was recorded in America, New Zealand and Europe. At Kew the resulting ground amplitude reached 290 μ at maximum. The earthquake of August 5 had its epicentre about lat. 25° N., long. 62° E. in the Arabian Sea, south of Baluchistan. It was registered in America and Europe, where the ground amplitude reached 250 μ at Stuttgart. It is not yet known whether the Tibet earthquake did any serious damage or not.

Deep-focus earthquakes occurred on July 13 east of the Fiji Islands (100 km. deep), on July 25 in the northern Argentine (400 km. deep) and on September 2 west of the Tonga Islands (200 km. deep). These demonstrate that the viscosity of the material in the earth was large at these depths, places and times, thus giving a clue to earth structure.

Two unusual epicentres are placed in North America; one on July 10 in Baffin Bay, recorded at American stations and Stuttgart, and the other on August 10 at lat. 41·9° N., long. 84·5° W., in southern Michigan, recorded in North America but not in Europe.

Also during the period movement was going on in mid-Atlantic, where an earthquake occurred at lat. 54° S., long. 30° W. near South Georgia on July 23, and one on August 9 at lat. 1° N., long. 28° W., the latter known to be a seismic area. On July 15 repeated earthquake shocks brought down the dome of the church of San Felipe at Pasto, Colombia, and destroyed the high altar. Houses also collapsed and serious damage was done to the University and to the airport. Four people were seriously injured, and the tremors may have been associated with the eruption of a volcano near the city. This shock may have been the one which was registered at De Bilt, Belgrade and Stuttgart near 14h. 30m. G.M.T.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, April 26

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Industrial Applications of Photo-electric Cells" (to be opened by Mr. F. Baxendale).

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5.30 p.m.—Dr. Edward Lynam: "English Surveyors and Mapmakers, 1555–1611".

INSTITUTION OF THE RUBBER INDUSTRY, MANCHESTER SECTION (at the Engineers' Club, Albert Square, Manchester), at 6.15 p.m.—Annual General Meeting.

Tuesday, April 27

BRITISH SOCIETY FOR INTERNATIONAL BIBLIOGRAPHY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2.30 p.m.—Papers.

UNIVERSITY COLLEGE, LONDON (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. D. B. Fry: "Speech". (Further lectures on May 4 and 11.)*

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. J. Wishart: "The Teaching of Statistics".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—James Forrest Lecture.

MANCHESTER GEOGRAPHICAL SOCIETY (in the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Dr. Mary Clarke: "Impressions of a Visit to China".

SOCIETY OF INSTRUMENT TECHNOLOGY (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Mr. A. J. Young: "Some Impressions of Modern American Instrumentation".

Tuesday, April 27—Friday, April 30

INSTITUTE OF WELDING (at Manchester).—Annual Spring Meeting.

Wednesday, April 28

PHYSICAL SOCIETY, COLOUR GROUP (at the Royal Photographic Society, 16 Prince's Gate, London, S.W.7), at 3.30 p.m.—Dr. R. K. Schofield: "The Report on Colour Terminology"; Discussion on "The Correlation of Colour Terms used in Physics, Industry and Ordinary Speech".

Royal Microscopical Society, Section of Industrial Microscopy (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 6 p.m.—Dr. F. Smithson: "Microscopy of Ceramic and Raw Materials".

Society of Chemical Industry, Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Seventeenth Annual General Meeting; Dr. E. B. Hughes: "On the Chemistry of Coffee".

Thursday, April 29

British Glaciological Society (joint meeting with the British Rheologists' Club and the Institute of Metals, at 4 Grosvenor Gardens, London, S.W.1), at 3.45 p.m.—Film illustrating the Methods of Glacier Research in the Field used by the Jungfraujoch Glaciological Research Party, 1938; at 5 p.m.—Discussion on "The Flow of Ice and of other Solids" (to be opened by Dr. E. Orowan, F.R.S., and Dr. M. F. Perutz).*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. D. M. S. Watson, F.R.S.: "The Mechanism of Evolution" (Hooker Lecture).

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. R. B. Giles: "The Economical Utilization of Electricity in Great Britain".

Royal Statistical Society, Sheffield Group of the Industrial Applications Section (at the Royal Victoria Hotel, Sheffield), at 6.30 p.m.—Mr. R. A. Nowlan: "Statistical Methods Applied to the Inspection and Testing of Aeronautical Materials".

Royal Institute of Chemistry, Manchester and District Section (at the Engineers' Club, Albert Square, Manchester), at 7 p.m.—Annual General Meeting; Mr. J. R. Whinfield: "Terylene".

Royal Photographic Society, Scientific and Technical Group (at 16 Prince's Gate, London, S.W.7), at 7 p.m.—Mr. G. A. Jones: "Tone Control with Unsharp Masks".

Friday, April 30

Physical Society, Optical Group (in the Physics Department, Imperial College of Science, Imperial Institute Road, London, S.W.7), at 3 p.m.—Seventh Annual General Meeting; at 3.15 p.m.—Prof. S. Tolansky: "Some Further Applications of Multiple-Beam Interferometry".

British Institution of Radio Engineers, Midland Section (at the Technical College, The Butts, Coventry), at 6.30 p.m.—Mr. J. Moir: "The Acoustic Aspects of High Quality Reproduction".

Institute of Physics, Manchester and District Branch (in the New Physics Theatre, The University, Manchester), at 6.30 p.m.—Annual General Meeting; at 7 p.m.—Dr. D. Shoenberg: "Superconductivity".

Institution of Electronics, North-Western Branch (in the Reynolds Hall, College of Technology, Manchester), at 6.30 p.m.—Mr. D. M. Corke: "The Application of Electronics to Vibration Research".

Manchester Statistical Society, Industrial Group (at the Society of Architects, 16 St. Mary's Parsonage, Manchester), at 6.45 p.m.—Mr. E. C. Fieller: "The Mathematics Division of the National Physical Laboratory, with special reference to Statistical Methods".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Harold Spencer Jones, F.R.S.: "The Age of the Universe".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Biologist, with B.Sc. in Zoology or Biology, and a Chemist, with B.Sc., preferably in Biochemistry—The Clerk, Birmingham Tame and Rea District Drainage Board, 117 Colmore Row, Birmingham 3 (April 30).

Engineering Scientist to the research department of a group of Companies in the North-West manufacturing a large range of textile machinery—The Ministry of Labour and National Service, Technical and Scientific Register, K Section, York House, Kingsway, London, W.C.2, quoting A.43/48A. (April 30).

Lecturer in Agriculture (Grassland Husbandry)—The Registrar, Wye College, Wye, Kent (April 30).

University Lecturer in Geography—The Secretary, Appointments Committee of the Faculty of Geography and Geology, Department of Geography, Downing Place, Cambridge (May 1).

Graduate Assistant in the Department of Biochemistry—The Administrator, Radcliffe Infirmary, Oxford (May 1).

Readership in Entomology at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 3).

Assistant Horticulturist in the Department of Agriculture, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (May 5).

Assistant Lecturer or a Lecturer in Geology, a Lecturer in Pure Mathematics, Assistant Lecturers in Applied Mathematics and Botany, an Assistant Lecturer in Geography, and a Demonstrator in Physics—The Registrar, University College, Singleton Park, Swansea (May 8).

Assistant Lecturer or Lecturer in the Department of Geography, an Assistant Lecturer or Lecturer in the Department of Physics, and an Assistant Lecturer in Economic Statistics—The Registrar, The University, Leeds 2 (May 8).

Assistant Lecturer in Mathematics, and a Lecturer or Assistant Lecturer in Geology—The Registrar, King's College, Strand, London, W.C.2 (May 8).

Lecturers (3) and an Assistant Lecturer in Natural Philosophy, and a Lecturer in Mathematics—The Secretary, The University, Aberdeen (May 10).

Senior Entomologist in a survey team investigating pest infestation in Nigeria—The Under-Secretary of State, Research Department, Colonial Office, Palace Chambers, Bridge Street, London, S.W.1 (May 10).

Demonstrator in the Department of Chemistry—The Secretary, Bedford College for Women, Regent's Park. London, N.W.1 (May 14).

Assistant Lecturer in Geology—The Registrar, University College, Southampton (May 15).

Lecturer in Experimental Physics—The Secretary, Queen's University, Belfast (May 15).

Lecturer or Assistant Lecturer in the Department of Geography—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (May 21).

Principal Research Officer or Senior Research Officer (Plant Physiologist), Division of Plant Industry, Canberra, Australia—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1642 (May 22).

Assistant Experimental Officers in Scientific Establishments in various Government Departments—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2162 (May 27).

Professor of Metallurgy at King's College, Newcastle-upon-Tyne—The Registrar, University Office, 46 North Bailey, Durham (May 28).

Lecturer (Grade II) in the Department of Chemistry (with special qualifications in organic chemistry)—The Registrar, Queen Mary College, Mile End Road, London, E.1 (May 31).

Head of the Department of Social and Economic Research, University College of the West Indies—The Under-Secretary of State, Research Department, Colonial Office, Palace Chambers, Bridge Street, London, S.W.1 (May 31).

Lecturer and an Assistant Lecturer in Statistics—The Registrar, Trinity College, Dublin (June 15).

Scientific Assistant for miscellaneous duties connected with a scientific information service and an abstracting journal—The Director, Commonwealth Bureau of Dairy Science, Shinfield, Reading, Berks.

Assistant Curator—The Curator of the Museum, Institute of Jamaica, Kingston, Jamaica, B.W.I.

Laboratory Technician (Grade B), and a Junior Student Laboratory Technician (Grade C), in the Department of Morbid Anatomy—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

Lecturer in Pedology—The Registrar, Wye College, Wye, Kent.

Inorganic Chemist for research—The Director, Tin Research Institute, Fraser Road, Greenford, Middlesex.

Lecturer in the Physics Department—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Laboratory Technician—The Director, British Welding Research Association, 29 Park Crescent, London, W.1.

Scientific Assistant (university graduate in science or agriculture)—The Director, Commonwealth Bureau of Animal Nutrition, Rowett Research Institute, Bucksburn, Aberdeenshire.

REHABILITATION OF EUROPE

IN April 1947, a report on the "Economic Conditions of Germany To-day and its International Repercussions" was issued by the special committee of the International Chamber of Commerce; a revised edition, submitted last November to the Council of the International Chamber, has now been published*. Certain of the recommendations of the original report have indeed already been adopted, wholly or in part. For example, a time limit has been given for completion of the earmarking of German machinery and equipment on reparations account, and plants not so earmarked are then to be finally freed from the threat of being taken for reparations. Great emphasis has been given to the problem of coal production, and German industrialists have been given incentive to export by permission to use part of the foreign exchange earned by the products exported to buy raw materials. There has been improvement in the procedure for exporting, and the steel output has now been raised to a limit of 10·7 instead of 5·8 million tons. The Committee, which again recommends that economic authority be given as much as possible to Germans, welcomes the initiative of the British and American authorities in creating a German Economic Council in their bizonal area, with full economic powers, subject to the overriding authority of the Allied Military Government. It also welcomes the adoption of the principle of the rapid devolution of power to central German agencies, and urges the resolute pursuit of this policy.

To restore incentive to the German workers and employers, four measures are recommended: monetary reform, involving a drastic reduction of the present volume of money, restoration of the market over an ever-widening area of the German economy by freeing the prices of non-essentials and gradual adjustment of the prices of controlled goods; fixing a new parity for the mark; extension of the system whereby family rations vary with the output and type of work done by the main wage-earner, and the gradual raising of normal rations; and provision for workers of greater quantities of consumer goods from domestic output and from limited and carefully selected imports, distributed so as to afford the maximum incentive to production. The Committee recommends that the goal should be for the management of Germany's heavy industries to be returned to private enterprise; but the substantial directive control, shareholding and management should be retained in Allied hands for reasons of security.

An increase in Germany's coal output is essential, both for the recovery of Western Europe and in order to terminate Germany's dependence on foreign financial aid; and every possible step should be taken to stimulate production as well as the work of repair and construction of Germany's transport system, and especially of locomotives and rolling stock.

The general aim of policy set out in the report is to reduce government controls as rapidly as possible, and to restore a system of free enterprise under which a genuinely democratic society and Government might be established. In framing their policy, the Control Authorities should bear in mind the needs of the rest of Europe and avoid a narrow outlook. The prime task of Europe to-day is to raise its overall production. That requires the use of the Continent's resources, transport and inland waterway facilities in the most efficient way possible, thereby minimizing Europe's overall foreign exchange deficit. If each country—and the Occupying Powers in Germany—seek to minimize their individual foreign exchange deficit unilaterally, the whole process of European reconstruction will be retarded and much effort wasted. Finally, the Committee observes that when political and other considerations make it possible to form a customs union or low-tariff area in Europe to which Germany could be joined, the solution of the economic difficulties of Germany and of the whole of Europe will be materially assisted.

---

* The Economic Conditions of Germany To-day and its International Repercussions. (Brochure No. 123.) Pp. 46. (Paris: International Chamber of Commerce, 38 Cours Albert 1.)

These recommendations, however, only indicate the scope of the report, which gives a clear picture of the situation to-day; quite apart from the suggestions as to the action required, it should materially assist in grasping the position now confronting us. An equally valuable contribution to that end is to be found in a broadsheet, "Local Government in Bizonia", which has been issued by Political and Economic Planning. This broadsheet, moreover, is a valuable study of the nature of democracy which merits attention quite as much from the point of view of the reorganisation of local government in Great Britain with which we are now faced.

The broadsheet is not intended to depreciate the difficulties involved in creating in Germany a democratic local government, or the value of the experiment that is being made in the British Zone. It questions, however, the wisdom of the British policy of following closely the system which has worked well in Britain, and suggests that the utmost flexibility and encouragement of bold improvisation are required. It recommends that much more freedom should be given in the British Zone, as is already done in the American Zone, for experiment, subject to supervision of general policy rather than of constitutional details, and exercised by people aware of local government as an adaptable instrument of administration.

The principles suggested in this broadsheet are not put forward as other than indicative rather than exhaustive. First, a clear line should be drawn between political appointments, whether full or part-time, and the non-political local government service under their direction. The best guarantee that legislation on these lines will be enforced is likely to be found in the service itself when its professional responsibility and *esprit de corps* can be developed. Full-time political administrators, it is thought, must either be elected directly by the people or indirectly by the German Economic Council, and in either case should be subject to re-election at frequent intervals as now happens in the American Zone. Financial control should remain with the Council, and the Council's officers must be answerable to the Council only. Where there is delegation of powers, it must be to the Council as a whole, which should be responsible for seeing that the work is carried out properly. The rights of party minorities must be recognized, and elected members are responsible to the electorate and not to outside members of their party. This means that while there may reasonably be consultation with outside organisations, decisions must be taken by the councillors, and outsiders have no right to see documents or to receive information not available to all electors.

The report from the International Chamber of Commerce makes it plain how closely Britain's own recovery is linked with that of Germany, and it is interesting to note a close parallelism of thought between that report and a recent "Design for Freedom" pamphlet. This pamphlet, entitled "Design For Recovery"*, argues that the failure of Britain to make the expected recovery from the effects of war is due largely to the Government's attempt to centralize the control of industry and to conduct trade on bilateral lines, as well as to irresponsible equalitarian propaganda, which has damped down individual effort. The recovery of Britain, it is urged, depends upon our overseas trade, and in this connexion emphasis is laid on the need for greatly increased production of the goods our customers require at prices they can afford, a restoration of multilateral trading, the re-establishment of sterling in its old position as an internationally accepted currency, and of freedom for the individual producer and trader to show his initiative.

Although the first recommendation is for a reduction of income tax by one third, the measures proposed in the pamphlet differ much less than might be expected from the policies of the Government. The earned income reliefs announced by Sir Stafford Cripps are designed to restore the incentives to greater production, which is the purpose of the reduction of the rate of tax advocated in the pamphlet; while the Government has already given evidence that it is concerned, where possible, to reduce the number of physical controls, to return to multilateral trade and to encourage the development of new sources of wealth. Even the strengthening of financial control, such as the rates of interest, control of credit and scientific taxation so as to reduce inflationary pressure, appear to be less distasteful; although there is as yet no evidence that either of the principal political parties is prepared to consider the fundamental reconstruction of the whole basis of taxation policy.

Much is said in the pamphlet about the importance of Colonial development; the present Government certainly cannot be accused of neglect of the latent resources of Colonial territories. The pamphlet, however, tends to neglect the practical and psychological difficulties which face any Government; although its support for the development of new resources, the encouragement of invention and the use of science to control pests and increase production should be welcome to the Government in view of some of its new proposals. Its criticism, moreover, points a way by which financial controls to reduce inflationary pressure may in themselves facilitate a large reduction of the physical controls which cause delay and waste, and encourage more fruitful co-ordination and stimulation in a freer economic life.

---

* Design for Recovery. Pp. 44. (Design for Freedom Committee, 22 Chester Square, S.W.1.)

Where the pamphlet links up its design with the International Chamber of Commerce report, however, is in its emphasis on European economic unity as essential to recovery. It urges as a first step the development of a system of currency interchangeability on the lines of the recent agreement by France, Italy and the Benelux countries, and that this agreement, utilizing the Bank of International Settlements, should be extended to all the sixteen nations participating in the European recovery programme. When Sir Brian Robertson, in his address on April 7 to the State Assembly of Rhine–Westphalia at Düsseldorf, affirmed the will of the Western Powers to pursue their plans for German recovery in face of the 'Iron Curtain' and the tense situation in Berlin, he called on the new Germany to take its place as one of the great nations of Western Europe. In his broad review of the political and economic scene, he gave no forecast of allied intentions for the progressive development of German political organisations or for the transfer of authority and responsibility to German hands; although he did emphasize that the ultimate objective of the bizonal administration in Frankfurt is to lay a foundation on which German unity with an independent, freely elected and representative government could be restored, a unity which would ensure to the people of Germany and their children the elementary freedoms of President Roosevelt.

The implications of this speech are as important as its content. The appeal to accept the prospects of security and reconstruction which the Marshall Plan and the Western Defence Pact offer mean that there can be no retreat at Berlin. While the division in Germany is absolute for the time being, Sir Brian's speech makes it clear that everything must be done to secure the confidence of the German people that the Western Powers will stand firm. Without that, plans and prospects everywhere in Germany, if not in Western Europe, will be shattered.

It is well that the British people as well as the German people should clearly understand what is at stake and how their future is interlocked. There has already been tabled in the House of Commons a motion urging the creation in Western Europe of a political union strong enough to save European democracy and the values of Western civilization, and a trading area large enough with the Colonial territories to enable its component parts to achieve economic recovery and stability. For this purpose the motion advocates the establishment forthwith of a Council of Western Europe consisting of representatives of the sixteen countries participating in the European Recovery Plan and Western Germany, with power to set up permanent international staffs to co-ordinate the social, economic and defence policies.

The first and most important task of the economic staff would be to frame concrete proposals for stabilizing the currencies of Western Europe, for the development of trade, for executing the European Recovery Plan, for a comprehensive production plan, including agriculture and the heavy industries, and for Colonial development. The long-term policy should be to create a democratic federation of Europe with a constitution based on the principles of common citizenship, political freedom and representative government, including a charter of human rights. Such a federation should have defined powers in such matters as external affairs, defence, currency, Customs and the planning of production, trade, power and transport.

Soviet intransigence has thus given an impetus to federation which a year ago was inconceivable. The convening of an assembly to frame a federal constitution for Western Europe has been brought within sight of the bounds of practical politics. In Great Britain, the idea of a United Europe, whether by federation or other means, has strong support from all political parties and has received powerful encouragement from statements made by the Foreign Secretary. Formidable difficulties will yet lie in the way of translating the declaration of principle into practical policies and bold executive measures, and success or failure will depend to a large extent on the support of an informed and intelligent public opinion. The pamphlets noticed above, no less than Sir Brian Robertson's speech, are to be welcomed as useful contributions to the formation of such an understanding and alert body of public opinion. The development of a body of opinion on this subject, not only in Britain but also in the other European countries concerned, is the indispensable first step towards the realization of any such long-term policy of federation contemplated in the second part of the all-party motion to which Mr. Churchill referred in the House of Commons on April 7.

SONS OF CAMBRIDGE

Alumni Cantabrigienses

A Biographical List of all known Students, Graduates and Holders of Office at the University of Cambridge, from the Earliest Times to 1900. Compiled by Dr. J. A. Venn. Part 2: From 1752 to 1900; Vol. 3: Gabb—Justamond. Pp. iv+619. (Cambridge: At the University Press, 1947.) £7 10*s*. net.

A WELCOME must be given to this further volume of Dr. Venn's *magnum opus*. Much of historical interest in the life of Britain is to be garnered in its 619 pages of biography. In reviewing them we shall not attempt to summarize the records of the divines, the statesmen, the medical men, the schoolmasters and the soldiers, but shall touch upon points of interest to scientific readers and upon some of the odd items of biography which enlighten its pages.

More than ninety fellows of the Royal Society have been noted, of whom the largest group consists of statesmen, lawyers and people in public life; the second group of mathematicians and astronomers; then representatives of medicine and the medical sciences, and then geologists. From among them mention may be made of William Hamilton, who saved for England the famous Rosetta stone; William Jones, the first Englishman to master Sanskrit; and Richard Gough, the archæologist, whose life in Cambridge must have been marred by shyness, for he scarcely ever stirred out of college without his tutor and he left his magnificent library to the Bodleian; also the Rev. William Vernon Harcourt, founder of the British Association. Other clergymen may be mentioned: William Hildyard, who had six sons who became fellows of colleges; James Inman, a Naval chaplain who improved ship-building and gunnery; Henry Gwyther who, when vicar of Yardley, caused three barrow-loads of parchments to be burnt; and John Jope, whose dead son haunted the church and vicarage of St. Cleer, Cornwall, until the father "consented to his remaining in the shape of a spider, and gave him as a hiding-place a crevice in the mantelpiece". His was a case which would have interested Edmund Gurney and Richard Hodgson of the Society for Psychical Research, who both appear in this volume.

Viceroys and governors head a long list of distinguished statesmen: here we will only mention James, Marquess of Graham, who obtained permission for the Highlanders to resume their national dress, long banned. Wars figure in the biographies of many soldiers and civilians turned soldier; we must mention William Hope, who won the V.C. in the Crimean War; William Hodson of Hodson's Horse, which did more than any other regiment to save India for the British at the time of the Mutiny. Travellers and explorers include Francis Guilleward (the Marquesas), Walter Harris (Morocco), George Haviland (Borneo), Sydney Hinde (Upper Congo) and Frederick Jackson (East Africa)—the original of Captain Good in "King Solomon's Mines". Books of adventure recall Henty and Cutcliffe Hyne, creator of Captain Kettle. Great athletes include Goldie, of the Goldie boathouse; Hockin, of immense size and strength, picturesque in his exhortations to a crew, who rowed seven years in the Jesus boat while it was 'head of the river'; the Gurdon brothers (Rugby football), Hammer Hales, S. S. Harris (association football), Lord Hawke, F. S. Jackson and A. O. Jones (cricket), L. K. Jarvis, a triple 'blue' and a member of the famous eleven that beat the Australians in 1878, Gatehouse (tricycle champion), and Hutchinson, who rowed with Steve Fairbairn for twenty-five years, and by a slip of the pen gave his age as '45' instead of '54' so as to get into the Durham Light Infantry in the First World War.

From the many miscellaneous items of interest a short selection must be made: Frederick Gill of Trinity was described by Francis Galton as possessing a grand nose, the glory of his College; John Griffith, chaplain of Ely gaol, bequeathed his housekeeper the ropes he received after each hanging, and she sold them for the cure of sore throats; A. P. Humphry, the long-distance shot, was reputed to have tested his marksmanship by firing from the tower of the Pitt Press on targets on the University range; Holditch, president of Caius for thirty-two years, was so shy and so rarely seen that a fellow of his own college once showed him round the college, taking him for a stranger. A wide range of similar stories is to be found by looking carefully through this interesting volume.

F. J. M. STRATTON

'LITTLE FLEAS' AND 'LESSER FLEAS'

Parasites (animaux et végétaux) des helminthes
Hyperparasites, ennemis et prédateurs des helminthes parasites et des helminthes libres; essai de compilation méthodique. Par Robert Ph. Dollfus. (Encyclopédie biologique, 27.) Pp. viii + 482. (Paris: Paul Lechevalier, 1946.) 1500 francs.

NOT only helminthologists, but others also who are interested in parasitism, will be grateful to Dr. R. Ph. Dollfus for this addition to his well-known and valuable work. For many years he has been collecting for his own use records of the hyperparasites and other enemies of trematodes and cestodes, and also of both parasitic and non-parasitic nematodes. He had no intention of publishing these; but his colleagues have urged him to do so, and the result is this very useful volume. The author does not claim that it is complete and he has published the various records as he found them, without critical evaluation by himself. Some of them consist of notes or a few words only, but the 26 pages of references enable the reader to consult the majority of the sources from which the records have been derived. Critical evaluations will, says Dr. Dollfus, come later, when the doubtful organisms recorded have been found and described again. We shall then perhaps be in a better position to decide whether there are any biological reasons for the fact that the records of the enemies of the cestodes and trematodes collected by Dr. Dollfus occupy only 50 of the 482 pages of the book, while the remaining pages are given to the enemies of the nematodes. It seems unlikely that this disproportion is the result of greater attention given either by Dr. Dollfus or by biologists in general to the enemies of the last-named group.

Prof. Emile Brumpt, in his introductory preface, regards the book as a first step in the study of an important field, and he suggests that the enemies of the helminths may influence the non-parasitic phases, at any rate, of their life-histories, as much as physico-chemical factors do. One may doubt this; but the suggestion certainly opens up a field of work which needs investigation.

Many readers will no doubt be astonished at the number and variety of the organisms which attack trematodes, cestodes and nematodes. Best-known among them perhaps are the fungi, which destroy by various methods both parasitic and non-parasitic nematodes; these are well described and illustrated in the 245 pages given to them. Readers who are interested in this subject will remember Dr. Drechsler's valuable and suggestive essay in *Biological Reviews* (16, 265; 1941). Less well known are the bacteria, spirochætes and protozoa which attack trematodes, cestodes and nematodes. The systematic position of some of these is still doubtful, and more work is needed upon them. In the bodies of trematodes phases of the life-histories of nematodes, trematodes and cestodes have been found; in some cestodes the larvæ of nematodes, cestodes and trematodes have been recorded; and, apart from the nematodes which eat other nematodes, there are species of this class which have been found inside the bodies of other species of nematodes.

Whether all the helminths which thus appear to be parasitic are really so or not we shall not know until much more work upon them has been done. Some of them may be only accidental associations and others may be instances of commensalism, similar to those associations between different species of nematodes which Dr. Dollfus does, in fact, describe as instances of commensalism. The distinction between commensalism and parasitism is not, of course, sharply defined, and, when organisms associated together are, like many of those mentioned in this book, comparatively difficult to obtain and certainly not easy to study under controlled conditions, it may be difficult to place them in either category.

What we need is more knowledge of the physiology of these organisms, and it may be that, in the process of acquiring it, new aspects of the relationships between parasitism and other forms of animal associations will be opened up. Dr. Dollfus has certainly provided in this book an extensive and detailed survey of such knowledge as we have, and it is to be hoped that he will follow it up with a critical estimate embodying his own wide experience.

G. LAPAGE

DIVINATION IN DAHOMEY

La Géomancie à l'ancienne Côte des Esclaves

Par Bernard Maupoil. (Université de Paris : Travaux et mémoires de l'Institut d'Ethnologie, Tome 42.) Pp. xxvii+690+8 plates. (Paris : Institut d'Ethnologie, 1943.) 320 francs.

M. MAUPOIL, during a tour of administrative duty in Lower Dahomey during 1933–36, made an extensive study of the Ifa system of divination, which plays such a large part in the religious life of the Yoruba and of their neighbours in Dahomey who have borrowed it from them. Although to the masses Ifa, or Fa as it is called in Dahomey, has become personified as a god, to the initiated it is more truly the voice of god or of fate. Unlike the cruel, capricious and unreliable gods of the Dahomey and Yoruba pantheon, Ifa is infallible, impartial, and never deceives. It consists of an abstract method of divination by manipulation of sixteen palm nuts, in the course of which a number of signs are made with the fingers in a yellow powder placed on a special tray. It is these signs which reveal to the initiated practitioner the past or the future. In its simpler form Ifa gives the consultant an answer to the everyday problems of his life; in its more esoteric, it gives him an opportunity of discovering his destiny.

Though Ifa may represent a man's fate and cannot be tricked or deceived, the Yoruba or Dahoman does not feel unduly terrified of his destiny, for there may still be a chance of avoiding it. This power which may enable a man to escape his fate is found in the conception of Legba, a being defined by Prof. Herskovits in his anthropological study of Dahomy as the personification of accident in a world where destiny is inexorable. M. Maupoil has of necessity a good deal to say about this roguish priapic messenger of the gods who spends his time deceiving both gods and mortals, and who plays such unpleasant tricks on them that early missionaries could only consider him the Dahoman personification of evil. He comes to the same conclusion as does Herskovits, that Legba is not the Dahoman counterpart of the devil, but that he supplies that principle of chance needed to humanize and make tolerable the rigid inexorable discipline of Ifa.

M. Maupoil is also impressed by the wisdom and sincerity of the Bokono (Yoruba, Babalawo), the priests or practitioners of Ifa, who play such an important part in Dahomey social life, a part sadly neglected and ignored by missionaries and administrators. The Bokono is called upon to intervene incessantly in social and family matters, and his balanced and philosophic outlook finds constant opportunity for expression through his divination. This wisdom, concealed in the proverbs and mythological tales by which the Ifa signs are revealed, helps to maintain the solidarity of the social group among whom the Bokono lives and practices, and gives it the equilibrium it needs to withstand the vicissitudes of its existence.

The absence of serious anthropological research on the Yoruba people and their sacred city of Ife constitutes a most unfortunate gap in our knowledge of West African peoples and their descendants in the New World. In default of such studies, students have, of necessity, to refer to works like the present one, which relate to peoples to whom this Yoruba culture has been transmitted. They will be very grateful to M. Maupoil for this most comprehensive study of Ifa. Though his field-work had necessarily to be confined to Dahomey, he has taken considerable trouble to consult, and where needed, to quote, all the available authorities on the Yoruba Ifa, in particular Mr. J. D. Clarke, some of whose notes have not received publication elsewhere. "La Géomancie à l'ancienne Côte des Esclaves" will therefore remain the standard work of reference on Ifa divination for many years to come.

G. I. JONES

ANATOMY OF THE RENAL CIRCULATION

Studies of the Renal Circulation

By Dr. Josep Trueta, Dr. Alfred E. Barclay, Dr. Kenneth J. Franklin, Peter M. Daniel, Marjorie M. L. Prichard. Pp. xix + 187. (Oxford : Blackwell Scientific Publications, Ltd., 1947.) 25s. net.

MOST text-books of histology provide detailed diagrams illustrating the intricacies of the vascular pattern in the kidney, and, indeed, the classical work of Bowman, Virchow, Huber, MacCallum and others would appear to have exhausted the purely anatomical aspect of this system. But it seems that this provides yet another example of those 'comprehensive' studies the completeness of which is only apparent. For evidence has now been adduced demonstrating that a fundamental point in the renal circulation has hitherto been entirely overlooked—the fact that it comprises a *dual* system. The kidney, it appears, has two potential circulations, a greater, which traverses the cortex and involves the cortical glomeruli, and a lesser, which is confined to the medulla and the juxta-cortical glomeruli. While in normal circumstances the circulating blood passes through the cortex, under certain conditions it may by-pass it entirely through the lesser circulation.

This is the theme, abundantly documented by experimental evidence, of the monograph which has recently appeared from the Nuffield Institute for Medical Research at Oxford. This monograph represents the product of team-work which was initiated in order to determine whether the renal failure which occurs in the victims of crushing injuries to the limbs might be due to reflex vascular disturbances. The results of the investigation depend largely on the application of angiographic studies in living animals, and also on a radiomicrographic technique which is evidently capable of providing extraordinarily accurate information of small but important vascular disturbances. With the aid of such methods, it was possible to demonstrate that by a variety of procedures (such as the application of a tourniquet to a limb, the stimulation of the sciatic nerve, and the injection of staphylococcus toxin) a cortical ischæmia in the kidney can be induced which may be severe enough to lead to an actual necrosis. The clinical implications of these observations are clear, and it is no exaggeration to say that they are of profound importance for the consideration of a number of problems of renal pathology, particularly since the vascular effects observed are believed to have primarily a neurogenic origin.

Undoubtedly one of the outstanding features of the monograph is the profusion of most excellent photographs demonstrating the effects of various procedures on the vascular pattern in the kidney. These certainly carry conviction so far as the actual recorded observations are concerned. While the authors make it clear that the precise relationship of these vascular changes to disturbances of renal function in pathological conditions is still a matter of hypothesis, they have nevertheless succeeded in directing attention to a factor which may well prove to be of major importance in their elucidation. The style of presentation is commendable for its directness and simplicity, and for the care which has been taken to avoid any over-statement of the case which the authors put forward.

REASON IN THE MODERN WORLD

Eclipse of Reason

By Max Horkheimer. Pp. ix+187. (New York and London: Oxford University Press, 1947.) 16*s.* net.

THIS is a rather difficult book; not that the author's exposition is unclear—on the contrary, he writes well; but that his general position is difficult to grasp. It is important to grasp it, because he makes a profoundly suggestive diagnosis of the intellectual sickness of our day.

The main thesis can perhaps be summarized without too much distortion as follows. The confusion of thought of the modern world is not just academically deplorable; it leads to confusion in political, economic and other social activities. It springs from deserting 'objective reason' for 'subjective reason'. The notion of objective reason is that there exists in the universe an intelligible order to which the thought and action of men should conform, as Plato and Aristotle believed. We have replaced that notion, through what is possibly an inevitable process, by subjective reason, which means obtaining an adequate mental grasp of socially approved means to ends. The ends themselves are left undefined as a sort of continuation of the means, or else interpreted as self-preservation, either of individuals or of some society on the preservation of which the individual life depends. In effect, such an attitude destroys all proper relations between society and individuals, and even makes the natural world appear to be the enemy of men or their master. (The argument for these conclusions is intricate and cannot be abbreviated.)

The favourite philosophies of to-day, the various forms of positivism, including pragmatism and Marxism, all adopt the point of view of subjective reason. In consequence they all become just 'ideologies' in the original sense of the term, propaganda for political parties disguised as rational discourse. Neo-Thomism is condemned by Prof. Horkheimer, though less severely, as archaistic, an attempt to revive something for which the necessary conditions have passed away. In its own way it also becomes political propaganda. Objective idealism of the Hegelian type is dismissed cursorily, though the author's way of thought appears to be akin to it. What is there left? The author says we need philosophy, but he is understandably cautious about putting forward another bit of political propaganda; so he says no more than that philosophy should be the memory and conscience of mankind. This is a pregnant saying, even if it means 'Back to Socrates'. Socrates has been more effective than other philosophers or than any of his contemporaries—but at a price. A. D. R.

ANIMALS AND THE LABORATORY

The UFAW Handbook on the Care and Management of Laboratory Animals

With an Appendix on Statistical Analysis. Edited by Prof. Alastair N. Worden. Pp. xvi+368. (London: Baillière, Tindall and Cox, 1947.) 31*s.* 6*d.*

SCIENCE owes much to animals employed in laboratories. Guinea pigs, rats, mice, ferrets, etc., have helped greatly in many a valuable research. The care of such animals is important, both from the humane point of view and that of scientific investigation. The handbook under notice, edited by Prof. Alastair Worden, is indeed a useful volume. There are some twenty-three chapters by various writers. Major Hume leads off with "Law and Practice: the Rights of Laboratory Animals", and his chapter is followed by one on the laboratory where animals are kept, including construction, equipment and so on. Pests of the animal house are next considered, after which we go on to the various animals commonly and uncommonly employed in laboratories, each chapter being written by an authority on the species being dealt with.

As might be expected, the rabbit has pride of place, with the guinea pig next and the Norway or brown rat in the third chapter; though some of us might have expected the mouse to come earlier than Chapter 5. Many animals have been pressed into the service of science, from the common house mouse, *Mus musculus*, to the field vole, *Microtus agrestis*, and their suitability by reason of size, ease of handling, rapidity of breeding and other characteristics is obvious at a glance; but the most remarkable on the list is undoubtedly the hedgehog. That this most unaccommodating creature, ever ready to roll itself into an impenetrable ball of prickles, should have been utilized in research work says much for the enthusiasm and ingenuity of the workers; but utilized it has been, and with success, and in this volume we can learn how to keep, feed and handle it, how to breed it, about its diseases, etc.

The book is a mine of information, and will be indispensable to all engaged in research where animals are employed. FRANCES PITT

A Manual of Vacuum Practice

By Dr. L. H. Martin and R. D. Hill. Pp. x+120. (Melbourne: Melbourne University Press; London: Oxford University Press, 1947.) 10*s.* 6*d.*

THIS manual, which is written by the professor and senior lecturer of the Physics Department of the University of Melbourne, is an excellent addition to the all too few modern books in the English language on vacuum technique. So many appliances to-day depend upon the production and maintenance of a high vacuum that not only the physicist and research workers in other branches of science, but also the engineer and many industrial technicians need to have a working knowledge of vacuum processes. No book can take the place of actual practical experience; but even the most experienced vacuum worker will find it extremely useful to keep by him such a handy reference book as this, for it describes in a concise and practical form not only modern developments in vacuum apparatus, but also presents in an easily accessible form valuable data concerning the properties and uses of materials most suitable for vacuum systems.

The physical principles of the production of low pressures, together with some typical calculations which were made in designing the pumping system for a neutron generator, are described in Chapter 1; the various gauges for pressure measurement in Chapter 2; pumps in Chapter 3; and materials, valves, joints, traps, etc., under the general heading of 'vacuum plumbing' in Chapter 4. Eighteen appendixes, including details with regard to soldering, cleaning of mercury, making glass-to-metal seals, and greases, waxes and cements, together with a comprehensive index, complete the volume. The clarity of the numerous diagrams and drawings, many of which are provided with actual dimensions, will be greatly appreciated by those who design and construct their own vacuum systems. Each chapter is provided with a list of references to the original sources, and the commercial apparatus referred to in the text includes both English and American types of the most modern pattern. The book is small enough to be slipped into the laboratory coat pocket. It is excellently printed and well bound with a special ring binding which allows the book to open and remain quite flat, an important feature especially when the user's hands are occupied with some practical job.

Aristotelian Society

Supplementary Volume 21: Explanation in History and Philosophy. The Symposia read at the Joint Session of the Aristotelian Society and the Mind Association at Cambridge, July 4th–6th, 1947. Pp. iv+218. (London: Harrison and Sons, Ltd., 1947.) 21*s.* net.

THE title of this modest little volume is a masterpiece of understatement. The contents are immeasurably richer than the word 'explanation' would suggest. Prof. C. D. Broad leads off with some characteristically stimulating observations upon methods in speculative philosophy. (Actually, his address came in the middle of the conference, not at the beginning.) The symposia proper deal with historical explanation, truth by convention, the psychological study of mental acts or dispositions, and the problem of guilt.

Interesting as all this is, it is hard to find much coherence, and harder still to get any very definite impression of aim. To attempt to do so would be misleading, beyond the remark that the headings do represent the spirit of the discussion. But the point is this, that the conference room was evidently a philosopher's workshop, where things could safely be left lying about, without having to tidy up for the night. This is one of the most promising and creative ways of fashioning thought, and the Aristotelian Society may be congratulated upon the results. No less a scholar than the late Canon Streeter commended the intellectual workshop, and was himself an adept in handling its tools and assembling the bits and pieces. The speakers reported in this book have done likewise and deserve our gratitude.

So far as the more strictly historical matter is concerned, it is wholesome to be reminded that events really did happen—for good or for ill—and that the sequence of occurrences has a reality of its own, independent of the design into which a later historian may desire to weave them. F. I. G. RAWLINS

Housing the Country Worker

By Michael F. Tilley. Pp. 152+24 plates. (London: Faber and Faber, Ltd., 1947.) 12*s.* 6*d.* net.

THE importance of housing in Britain in relation to agriculture and the use of the land in rural areas was well brought out in the Scott Report, and has been stressed in recent discussions in connexion with the Government's agricultural policy and the housing situation in general. Mr. Tilley has discussed lucidly and most readably the broad aspects of the whole problem as seen against the changes in farming organisation and practice, the rural location of industry and the political, economic and social questions involved. There is an admirable chapter on the village plan, followed by others on the provision of public services, the repair and reconditioning of old buildings, the needs of the country worker as distinct from the urban dweller, recent housing developments and materials and equipment. This sane and balanced discussion, which always has close regard to the personal needs of those primarily concerned as well as to what is practicable, taking into account the materials available and the efficient use of sites and land, points the way towards harmonizing anew the erection of new houses and the advent of a new population on one hand and the existing structure of the village in all its aspects. These possibilities are clearly indicated, and the book should be read with interest not merely by the architect or builder, the rural councillor or others actively concerned with the preservation of the countryside, but also by the townsman accustomed to use the country as a week-end resort or daily dormitory. There is much in this book which should further the establishment of good relations between town and country as well as the new tradition of good planning and building worthy of the best in the past, to foster which is the primary purpose of the book. R. B.

A Planned Auxiliary Language

By H. Jacob. Pp. 160. (London: Dennis Dobson, Ltd., 1947.) 10*s.* 6*d.* net.

ONE of the suggestions for the scientific programme of the United Nations Scientific and Cultural Organisation made by the Mexican Delegation at the Conference of the Natural Science Committee of the Preparatory Commission in June last year was that a single international scientific language should be chosen from among German, English, Spanish, French, Latin, Russian and Chinese as the official language for international scientific conferences, congresses and other meetings, and scientific works written in any other language should always include a sufficiently full summary in this international language. The difficulties in the way of adopting any suggestion on these lines are obvious, though the numerous international scientific conferences during the past year have directed fresh attention to the need. This comparative review of the five systems of planned international language already proposed—Esperanto, Ido, Occidental, Novial, and Interlingua—merits careful consideration. Dr. H. E. Palmer contributes a preface describing the various approaches which have led to the proposals for artificial or planned languages, and after discussing the functions of a planned language, Mr. Jacob describes the five systems and then considers in succession the structural problems of the planned language and present-day movements in this field. Two chapters on the preliminary project of the Russian Academy of Sciences for a technical nomenclature, and on technology and the language problem, appear to exaggerate the barrier which language has placed to technical communication, and the treatment of nomenclature is altogether too superficial. There is an adequate bibliography.

Petroleum Production

By Park J. Jones. Vol. 3: Oil Production by Water. Pp. vii+271. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1947.) 30*s.* net.

WATER in oilfield development can be both a blessing and a curse. This volume deals with the former condition, although the alternative never seems far behind. Briefly, recoverable oil can be classified as dry, wet and marginal reserve. "The ratio of dry to wet oil reserve depends on how soon water appears in production." Obviously it is far more economical in every sense to produce dry oil than wet oil, and every operator strives to achieve the first, if not to control the second to his advantage.

In this thesis of oil production by water, theoretical considerations take care of the normal condition 'oil ahead of water', oil production by expansion, well producing capacity, injection of water, optima for reservoirs and oil migration. Practical applications concern radial reservoirs, two-pay intervals, impermeable wedges, saturated oil, linear and elongated reservoirs and bottom water. The author is clearly a master of his subject, but the reader needs more than average mathematical knowledge to follow all the arguments. The book is well produced and the text clarified by numerous graphs and line drawings.

H. B. Milner

New Developments in Ferromagnetic Materials

With Introductory Chapters on the Statics and the Dynamics of Ferromagnetism. By J. L. Snoek. (Monographs on the Progress of Research in Holland during the War.) Pp. viii+136. (New York and Amsterdam: Elsevier Publishing Co., Inc., 1947.) 6.75 fl.

QUITE apart from any other, this brochure is of interest as illustrating some of the work done by Dutch men of science during the period of the German occupation. Starting off with general accounts of what the author terms the statics and dynamics of ferromagnetism, the main interest lies in the work done on the development of new magnetic materials based on the cubic $M\mathrm{O.Fe_2O_3}$ compounds. The interesting fact emerges that the oxides containing zinc have higher permeabilities than the rest, presumably because the Curie point is lowered, the maximum permeability being found to occur just below this temperature. The samples are prepared by a sintering technique which is described, and in the case of mixed NiO, ZnO compounds, a maximum initial permeability of 4,000 has been obtained. Among the appendixes is one dealing with the decarburization of steel. The author claims that the rate of diffusion of carbon in α-iron is very much higher than that in the γ-modification, a view which is contrary to current opinion, and which requires further confirmation before it can be accepted.

F. C. T.

Proceedings of the First Canadian Mathematical Congress, Montreal, 1945

Pp. xliv+367. (Toronto: University of Toronto Press, 1946.) 3.25 dollars.

CANADIAN mathematics, at least in the English-speaking provinces, followed closely the English pattern of the nineteenth century. On the other hand, the Canadian school system had many points in common with that of the United States. As years elapsed, the distance of Canada from Great Britain and the traditional fear of being dominated by the United States prevented Canada from following the mathematical advances in either of these countries. This tendency towards isolationism has been aggravated by the lack of intercourse between different parts of Canada itself. A great step in overcoming these defects has been taken by the institution of the Canadian Mathematical Congress, the first meeting of which took place at Montreal in 1945. There were several lectures, some by Canadians and some by distinguished visitors such as G. Birkhoff and L. J. Mordell, research papers, and discussions on methods of fostering research work, on recent advances in statistics, and on the teaching of mathematics to engineering students and in schools. Most of the proceedings were in English, but a few were in French. It was resolved to recommend the founding of a mathematical journal.

H. T. H. P.

Mathematik, Logik und Erfahrung

Von Prof. Dr. Victor Kraft. Pp. vii+129. (Wien: Springer-Verlag, 1947.) 10 francs.

IN this modest little volume are signs of intense application and erudition, under conditions (in Vienna) truly 'impossible' as judged by British standards. There is nothing very new in these pages, suggestive as they are. The first half of the book deals with the empirical validity of mathematics—arithmetic and geometry—whereas the second is concerned with a spirited refutation of 'conventionalism', and a discussion of the conditions of application of logic. The prospective reader will naturally ask what this particular brand of conventionalism is to which Prof. Kraft devotes so much attention. It seems to be a species of what we should call idealism in natural law. By relegating it to the *Hinterland*, a healthy relationship is probably established (especially for the intellectual climate in which the author writes) between physics and epistemology; on the other hand, if everybody went all the way with him, there would be but scant quarters left for the 'poetry' of science, of which recent years have produced superb examples in other parts of the world. Nevertheless, Prof. Kraft has enriched his subject, and added distinction to its literature.

F. I. G. Rawlins

AFRICAN FOSSIL PRIMATES DISCOVERED DURING 1947*

By PROF. W. E. LE GROS CLARK, F.R.S.
Department of Human Anatomy, Oxford

THE elucidation of the fossil record of the group of mammals of which man himself is a member is clearly a matter of the most profound interest. But it is a study which in the past has progressed extremely slowly, for the reason that the remains of fossil Primates are usually found only at rare intervals. It is all the more remarkable, therefore, that the year 1947 was outstanding in the field of palæontology for the great abundance of extinct representatives of the higher Primates, the Hominoidea, which have come to light. These discoveries were made in Africa, and it is particularly interesting to note that they followed so closely on the Pan-African Congress of Prehistory, held in Nairobi in January of that year, when the implications of earlier finds first gained a wide recognition. The discoveries are due primarily to two men of science, Dr. Robert Broom in South Africa and Dr. L. S. B. Leakey in Kenya.

The new discoveries made by Dr. Broom supplement those which he made between 1936 and 1941 at Sterkfontein and Kromdraai, and which he described in detail in a monograph published in 1946[1]. They are remarkable both in quantity and quality, for not only do they include considerable numbers of skulls, jaws, teeth and limb-bones of the Australopithecinæ, but also some of this material is extraordinarily complete and well preserved.

It will be recalled that the first specimen of the Australopithecinæ, an immature skull with an endocranial cast, was found at Taungs in 1924 and afterwards described by Prof. Raymond Dart[2]. Then in 1936 and later, Dr. Broom found portions of several adult skulls, jaws and teeth, as well as fragments of some limb-bones, at Sterkfontein and Kromdraai near Johannesburg. His report on this material made it clear that the Australopithecinæ were ape-like creatures with brains of simian dimensions, but which at the same time showed such a remarkable assemblage of characters hitherto regarded as distinctive of the Hominidæ that there could be little doubt of their importance for problems of human evolution. Among these hominid characters may be mentioned the morphology of the frontal region of the skull, the low level of the occipital torus, the construction of the tympanic region, the forward position of the foramen magnum, the palatal contour, the small canines, the bicuspid character of the anterior lower premolars, the morphology of the first deciduous molars, the flat wear of the molars, the details of the lower end of the femur, and certain features of the talus and the capitate bone. The evidence of the femur, combined with that of the foramen magnum, it should be noted, seemed to make it clear that the Australopithecinæ were capable of assuming an erect posture closely approaching that of man.

This accumulation of evidence was sufficient to convince most anatomists that the importance of the Australopithecinæ had not been exaggerated. A few critics, however, expressed scepticism, mainly, no doubt, because they had not had the opportunity of examining the original material for themselves. It is also a fact, however, that this material, although abundant, was in some respects fragmentary, and thus required a rather intimate acquaintance with the comparative osteology of the Hominoidea for a correct appreciation of its unusual characters. Early in 1947, Dr. Broom renewed his excavations at Sterkfontein, and in April announced the discovery of a practically complete adult Australopithecine skull, as well as the upper jaw of another adult, an upper jaw of an adolescent, and some isolated teeth[3]. The complete skull has been listed in the material from Sterkfontein as "Skull No. 5". Further excavations soon showed that many more remains of the Australopithecine fossils were embedded in the limestone matrix in the same area at Sterkfontein, and parts of at least five other skulls (some of which are fairly complete) have since come to hand. The preliminary notes on these discoveries so far published have now provided a remarkable vindication of the views previously expressed by those who had personally studied the earlier material described by Dart and Broom. For example, they appear to confirm the forward position of the foramen magnum and the human resemblances in the occipital and tympanic regions, while many other features such as the contour of the frontal region and the shape of the dental arcade conform closely with the evidence already supplied by less complete material. The discovery of a massive jaw in June 1947, with all the teeth in position, has also added further evidence that the canine was relatively small (compared with the premolars) and became worn down flat to the level of the adjacent teeth[4]. In all these skulls the endocranial capacity seems to vary about 500 c.c.

Dr. Broom, however, has not only found a number of skulls, but has also collected a considerable number of limb-bone fragments, including portions of a scapula, humerus and femur, a tibia, some ribs and vertebræ, and an almost complete os innominatum[5]. The last-named is without doubt the most remarkable find. In the shape of the ilium it corresponds very closely with that of man, and shows no resemblance at all to the os innominatum of an anthropoid ape. Indeed, it provides the final proof (if further proof were needed) that the Australopithecinæ stood and walked in approximately human fashion. So human in appearance is this fossil bone that the question may well be raised whether it really is part of an Australopithecine skeleton. But, apart from the fact that it is entirely consistent with the evidence previously provided by the femur and talus (and also the construction of the base of the skull), it was actually found by Dr. Broom embedded in a block of limestone matrix with portions of several other limb-bones, vertebræ and ribs and with a crushed Australopithecine skull. There can scarcely be any doubt, therefore, that all these bones are the remains of the skeleton of a single individual. It should be noted, also, that in certain features of the os innominatum, such as the details of the ischial tuberosity, it shows unusual characters which, it seems, are not paralleled either in the modern anthropoid apes or man.

---

* Substance of a communication to the Linnean Society, April 22, 1948.

It will naturally be some time before a detailed account of all this new material from Sterkfontein can be published, but private communications, together with unpublished photographs and drawings, make it clear that the information now available on the anatomy of the Australopithecinæ is astonishingly complete. Stated briefly, they are ape-like creatures in respect of the general proportions of the brain-case and jaws, but approach the Hominidæ closely in the constructional details of the skull, in numerous features of the dentition, and particularly in the limb skeleton. There is no sign yet that the rich 'lode' of Australopithecine material discovered by Dr. Broom is yet approaching exhaustion, and thus there is a reasonable possibility that further remains of the hand and foot skeleton may be found which will permit an even more precise definition of the status of these extinct hominoids. But, when all the evidence now available is published, systematists will inevitably be faced with the question whether the Australopithecinæ should not be allocated to the Hominidæ rather than the Pongidæ.

Simultaneously with these remarkable discoveries of fossil hominoids in South Africa, discoveries of similar importance were being made in Early Miocene deposits of Kenya by Dr. L. S. B. Leakey and Dr. D. McInnes. In 1931, Dr. A. T. Hopwood described some fossil jaws and teeth recovered from Koru in Kenya and assigned them to three new genera of extinct anthropoid apes, *Proconsul*, *Xenopithecus* and *Limnopithecus*[6]. Afterwards, more Early Miocene material referable to these genera were obtained on Rusinga Island and adjacent areas by Leakey[7] and McInnes, and were described by the latter in 1943[8]. Following the Pan-African Congress on Prehistory, some of the delegates had the opportunity of visiting the sites of these discoveries and were impressed with the possibilities of further excavation. A British-Kenya Miocene Expedition was therefore organised with the aid of a grant from the Royal Society, with Dr. Leakey as field director. The expedition proved to be an outstanding success, for almost fifty specimens of fossil hominoids were collected[9]. This material is now being examined in the Department of Anatomy at Oxford, and the brief account which follows is entirely of a preliminary nature. Perhaps the most striking feature of the collection is the great variety of fossil apes which it represents. Before the first discoveries in Kenya, the only certain information available about fossil apes which existed earlier than the Middle Miocene was provided by two fragmentary jaws from the Oligocene of Egypt, *Parapithecus* and *Propliopithecus*. Now, with the accession of all the new material from Kenya, we are faced with such a bewildering variety of Early Miocene apes that it is by no means an easy matter to sort them all out. Much of the material consists of jaws and teeth of an ape considerably larger than *Proconsul africanus* (Hopwood), and in which the relative sizes of the premolars and molars, as well as the cusp pattern of the latter, also show differences. There is little doubt, therefore, that they should be assigned to a different species. To this group belongs the almost complete mandible found on Rusinga Island in 1942, as has now been established by the discovery during 1947 of a portion of the maxilla of the same individual, with the cheek teeth in position. A still larger species is represented by portions of a huge mandible found by the British-Kenya Miocene Expedition at Songhor. This jaw is in some respects more massive than that of many adult male gorillas.

In all these specimens (which provisionally are regarded as constituting several species of the genus *Proconsul*), there are certain characteristic features. The incisors are relatively small in comparison with modern apes, and the symphysial region of the jaw is narrow, the axis of the symphysis tending to be more vertical; the canines are large and there is little definite evidence of any marked sexual difference; the first lower molar is proportionately rather small, the upper molars have a well-developed internal cingulum which in some cases is elaborately beaded, and the lower molars have very evident traces of an external cingulum. Some immature jaws of *Proconsul* which have been found are particularly instructive for the information which they give on the dental succession in these primitive apes. Of similar dimensions to *Proconsul*, but with a very different cusp pattern, are a number of upper teeth found at Rusinga and the surrounding area. These show some resemblance to the teeth of the Middle Miocene Indian genus, *Sivapithecus*, and in the absence of a strongly developed internal cingulum presumably represent a type which is more generalized (or perhaps more advanced) than *Proconsul*. But more material of this type is needed before a definite diagnosis can be made.

Portions of upper and lower jaws of *Xenopithecus* with the teeth in position have now made it possible to make a fairly complete study of the dentition of this genus, and to demonstrate that it differs from *Proconsul* mainly in its smaller size and in the elongation of the last lower molar. Still smaller than *Xenopithecus* is the gibbon-like *Limnopithecus*, of which a number of jaw fragments are now available and also a maxilla and palate with the upper premolars and molars. It now appears probable, from this material, that at least two species of *Limnopithecus* existed in East Africa in the Early Miocene.

Only a few limb-bones of the Early Miocene hominoids have so far been found, but these have provided information of unusual interest. The femur provisionally referred to *Proconsul* is a long, slender and straight bone, very similar to the Eppelsheim femur, which is probably that of *Dryopithecus*. The humerus is likewise of somewhat delicate construction and, though of about the same length as that of an adult chimpanzee, lacks the powerful muscular ridges which are associated with brachiating habits. The talus and calcaneus of *Proconsul* have already been described by McInnes. It is a striking fact that, in many of their details, they conform much more closely to the corresponding tarsal bones of the cercopithecoid monkeys than those of the modern large apes. It is probable, indeed, that *Proconsul* was not a brachiating specialist, but led a more cursorial type of existence. Combined with certain features of the femur, the tarsal bones indicate that these Early Miocene apes were lightly built and active creatures, capable of running and leaping with considerable agility.

These observations will certainly have an important bearing on the problem of the evolution of the higher Primates, for they suggest that the adoption of the brachiating habits which are characteristic of the modern apes may have been a relatively late acquisition. More limb-bone material of the Early Miocene apes of East Africa is needed in order to follow up the very interesting implications of the specimens already available, and we require also to know more about the structure of the skull (which we have already learned was much shorter in the facial region than in the recent large apes). There is a reasonable prospect that, in continuing their excavations during the coming season, Dr. Leakey and Dr. McInnes may be able to secure this important evidence. Meanwhile, it is not a little remarkable to find, as the result of the excavations in Kenya, that already in Early Miocene times East Africa was populated with numerous species of primitive apes ranging in close gradations of size from small creatures no larger than *Hylobates* to great apes of gorilloid dimensions.

BRITAIN'S FUEL PROBLEMS

THE authoritative reports issued periodically by P.E.P. (Political and Economic Planning)—an independent non-party organisation—have established for the compilers a reputation for clearly argued, factual and objective analyses to which industry and politicians alike may turn for guidance. Before the War, P.E.P. had issued reports dealing with the coal industry (1936), the electricity supply industry (1936) and the gas industry (1939) of Britain; all are now out of print. But for the War, a fourth report, on the co-ordination of the fuel and power industries, would have followed in natural sequence; and the need for such co-ordination became one of the principal reasons for the formation of the Ministry of Fuel and Power in 1942. "The British Fuel and Power Industries", published at the end of 1947*, reviews developments which have taken place since the earlier reports were issued. It does not argue the advantages or disadvantages of nationalization, and was prepared on the assumption that before long the major fuel industries would, in fact, be brought under national ownership. One aim was to indicate some of the steps necessary to bring these industries to a state of the fullest efficiency, and to suggest broad lines along which their co-ordination might be achieved.

The report invites use as a reference rather than as a book to be read; but an immediate clear summary of some fifty pages outlines the contents in bold précis. As most readers will make an approach from this summary, it might have been helpful had cross-reference been made in it to the 160 tables of valuable data which follow in the text. Both the summary and the text are arranged in four main sections; the first dealing with national resources, productive capacity and output; the second with consumption and market requirements (including a technical appendix relating to the iron and steel and textile industries), the third with organisation and relations with Government, and the fourth with co-ordination of the fuel and power industries.

It is estimated that on the basis of net useful therms supplied, coal accounted in 1945 for more than 90 per cent of the total British fuel consumption, imported petroleum products (including motor spirit) for about 9 per cent, and hydro-electric power and oil from indigenous petroleum and shales for well under 1 per cent. Full development of hydro-electric resources, including those in Scotland and North Wales, might provide an equivalent of 3 per cent of present coal output; the potential output of the Severn Barrage is equivalent to 0·5 per cent. Except for the possibilities inherent in the development of atomic energy, no great change in the proportionate consumption stated is anticipated, unless by an increase in imports of petroleum products at the expense of the country's balance of payments; and while there are no grounds for anxiety regarding the adequacy of total supplies or of particular types of coal over the next hundred years, total proved reserves are much less than estimated forty years ago. No mention is made of possible coal reserves revealed by recent prospecting for oil.

The report indicates that the exhaustion of the best low-ash seams, the increased use of mechanical means of coal winning, etc., call for more extensive preparation of coal for the market, and full co-operation between the producer, consumer and appliance manufacturer; a major problem is the disposal of fine coal, and research and development work are necessary. In view of shortage of coal on the home market, exports have been restricted since 1941; it is debatable whether in the long run large quantities of coal, a wasting asset, should be exported, but coal exports at the level prevailing before the War would make a substantial contribution to the national economy.

With the rapid growth of electricity generation, use of waste heat from power stations represents an important potential contribution to fuel conservation; and while there is scope for greater development of combined power and heating plants, the extensive development of district heating to utilize waste heat from existing power stations is considered economically impracticable. The possibility of district heating should, however, be taken into account in deciding the location of new power stations.

In the iron and steel industry, better geographical distribution and further integration are most likely to reduce fuel consumption. Blast furnaces are the most important single fuel-consuming plants, the coal equivalent of the coke consumed therein increasing from 6 per cent of total coal output in 1937 to nearly 8 per cent in 1944; increase in size of blast furnaces is desirable. In the textile industries, space-heating accounts for 70 per cent of the total fuel consumption in cotton weaving and for 40 per cent in worsted spinning; indeed, the seasonal nature of industrial fuel consumption suggests that the use for space-heating is considerable.

It is stated that a sound national fuel policy can be based only on a detailed knowledge of trends in fuel usage, and fuller information is necessary. Much has been obtained by various fuel efficiency committees and Government departments, but little has yet been collated and published; indeed, there is need for a regular audit of the fuel balance of all industrial users. On grounds of thermal efficiency, the large amount of coal used for steam raising is unlikely to be replaced by any form of processed coal or alternative fuels; in furnace firing, the overall efficiency of utilization of coal is low, and gas, liquid fuel or electricity have technical advantages in partic-

* The British Fuel and Power Industries. A Report by P.E.P. Pp. xi+406. (London: P.E.P., 1947.) 30*s*. net.

ular instances. Solid fuel will be compelled to carry the main load for domestic use for many years to come, if only because in this form sufficient stocks can be provided to meet peak loads ; for continuous space-heating of domestic premises, the most efficient appliances are solid-fuel closed or closable fires, and gas fires with convection.

After reviewing technical considerations affecting uses, the report passes to discussion of the possibilities of tariff co-ordination as a means for securing the best use of the national fuel resources of Britain, but without being able to lay down any novel basis. In order that consumers' choice of fuel coincides with national interest regarding resources and smoke abatement, close attention should be paid to the tariff structure of individual fuel supply industries ; subject to certain exceptions to cover promotional tariffs and the uneconomical consumer, tariffs should be closely related to cost of production and supply. Special importance is attached to regulation of coal prices ; relative prices for various grades and qualities must exert strong influence on trend of consumption and rate of development of the gas and electricity industries. The report recognizes the difficulties involved, and proposes tariff commissions for individual industries, guided by a national authority, probably the Ministry of Fuel and Power ; while unrestricted price competition is undesirable, administrative and technological competition has on the whole been of great benefit. There is a serious shortage of fuel technologists and the knowledge of the general public is small.

Even if the report leaves one a little in the air, it is invaluable at the present moment ; it will serve for some time as the most readily available guide. Reference may perhaps be made to the remarkable statement on page 131 : "the earth's internal store of thermal energy is dependent for its maintenance on solar radiation" ; and an omission in discussing possible future trends is reference to the gas turbine, for opinion recently expressed is that the raw coal turbine looks to most engineers a likely practical proposition for industrial service years ahead of atomic energy.

UNIVERSITY OF PRAGUE SEXCENTENARY CELEBRATIONS

By DR. GERALD DRUCE

THE six hundredth anniversary of the founding of the Charles University of Prague was celebrated during the week commencing April 4. The precise date of its foundation is usually given as April 7, 1348, the day on which Charles, as King of Bohemia, issued his charter setting out the reasons for the institution of a seat of higher learning in the Czech capital. Until 1355, when the Carolinum was ready, tuition had to be given in religious buildings and in private houses that had previously served as Latin schools. The original building, enlarged and renovated, still serves for important University functions and was used for some of this year's ceremonies. For the general gatherings use was made of the large Vladislav Hall of the Hradčany Castle, which is capable of seating several thousands.

The first assembly was mainly for Czechoslovak participants, and included, as well as members of the University, several Cabinet Ministers, prominent ecclesiastics, authors and representatives of the arts and sciences, workers' educational associations and students. The Czechoslovak Premier, Mr. Klement Gottwald, reminded the assembly that during its long history the University had given the world many great men of science and thinkers and that it entered upon its seventh century at a time of considerable social and economic change from which, it is hoped, a better world is being born. In such a world the University will have a still greater mission to fulfil since more scientific men and other scholars than ever before will be needed.

Prof. Bohumil Bydžovský, rector of the University, dealt at length with the University's significance for the nation's cultural and intellectual life. "For us the Carolinum is a symbol of the struggle for truth and for spiritual and ethical perfection and progress." He stressed the contributions of John Hus and of T. G. Masaryk at different stages of its history. Prof. Z. Nejedlý, Minister for Education and president of the Czech Academy, pointed out that the University has always been associated with national aspirations and its influence to-day is as great as ever, and so are the tasks before it.

Messages of congratulation were given by Profs. Seifert and Rysavý respectively, on behalf of the sister University of Brno and the Prague Technical College, and by a representative of the students.

On the actual anniversary, the hall was filled with distinguished people and students when the procession of foreign delegates, the rector, members of the Senate, the deans and professors of the Charles University and of the other Czechoslovak universities entered. The rector escorted President Beneš to his seat, welcoming the visitors in short speeches in four languages, referring again to the University's part in the nation's historical evolution. He mentioned its early contacts with other universities, especially those of Paris and Oxford, expressing gratitude to Oxford in particular for allowing Czech students to complete their studies there when the Czech universities were closed in 1939. He expressed his deep regret that British universities and those of some other countries had not accepted the invitations to participate in this historic ceremony.

In presenting the renewed charter, written on parchment by Prof. J. Benda of the School of Fine Arts, to replace the original that disappeared during the German occupation, President Beneš pointed out how moral and political issues profoundly affected the fate of seats of learning, which could always be found on the side of recognized truth, liberty and morality. It was from the University that so many honorable and wise men arose to lead the nation in both glorious and difficult times ; but the Charles University had never been able to celebrate its centenaries in peace and tranquillity. Its first centenary occurred when King George of Poděbrady was vainly trying to set up the first league of nations. In 1548 the first Czech revolt against the Habsburgs was being heavily suppressed. The Peace of Westphalia in 1648 followed the Thirty Years War that had devastated and depopulated the kingdom, then in bondage with the University in foreign hands. The year 1748 fell between two more wars that were disastrous for the Czech people, apart from the added contemporary dangers of Austrian measures of centralization and Germanization. Finally, the year 1848, which brought the beginnings of constitutionalism to the Slavs, was also one of storms, and not even to-day are the celebrations taking place in tranquil times. Three years after the most terrible war in history there is still no such peace as is longed for so ardently. If this human longing, accompanied by freedom of belief, science, thought and profession, is to be fulfilled, President Beneš said, it is even more necessary to realize a universal freedom of the spirit. This freedom, founded on man's respect for man and on the common tolerance traditionally associated with the Charles University, will lead once more to a happy prosperity and a truly happy future.

The preamble in Czech and the Latin text of the renewed charter were read out by Prof. Nejedlý.

Prof. Jean Sarrailh, rector of the Sorbonne, gave a congratulatory address on behalf of the visitors. He referred to the links between Prague and other universities, and mentioned that the Czech scholar, Albertus Ranconis, came from the Charles University to Paris, where he was rector of the Sorbonne in 1355. Educated at Paris, Charles IV had carried French educational traditions back to Bohemia, where Hus was soon to make a stand for religious freedom and social justice. The successful extension of learning was interrupted by the Habsburgs, who even banned the use of the Czech language; and it was not until 1918 that free cultural activities could be resumed at the Charles University. Since then, Czech culture and civilization has become better known in France and elsewhere through the work of Prof. Ernest Denis, who also enabled Czech pupils to attend high schools at Nîmes and Dijon, where Eduard Beneš studied. The development of Czech culture was again interrupted by the German occupation in 1939; but no force can for ever prevail over the spirit, and the University is again happily in Czech hands. Prof. Sarrailh concluded, "Ainsi, comme au Moyen-Age, votre Université remplira son rôle international. Fidèle au grand rêve de Georges de Poděbrady, le plus populaire de vos rois, elle travaillera à l'avènement de la paix universelle et restera le temple de science et de progrès humain qu'avait voulu faire d'elle son fondateur".

A students' representative, M. Grohmann, spoke *extempore* in four languages, before the delegates of foreign universities presented illuminated scrolls to the rector.

On the following day, honorary doctorates were conferred at the Carolinum on about forty distinguished savants representing all branches of learning, including science and medicine. The theological faculty awarded a degree to Cardinal Mercatti, archivist at the Vatican; the medical faculty gave degrees to Prof. R. Leriche of the Collège de France, Prof. L. A. Orbelli of Leningrad and Prof. P. D. White of Harvard. The awards of the philosophical faculty went mainly to specialists in Slavonic subjects, such as Prof. André Mazon of Paris and Prof. Ali A. Siassi, rector of Teheran University. The natural science degrees were conferred upon Prof. P. E. Eskola of Helsinki, Prof. B. Isačenko of Moscow, Prof. S. J. Jakovljevič of Belgrade, Prof. L. Růžička of Zurich, Prof. W. Sierpinski of Warsaw and Prof. S. I. Vavilov of Moscow. The only Czechoslovak recipient was the Minister of Education, Prof. Z. Nejedlý, who recalled how he had graduated in the same hall forty-eight years earlier. A number of the degrees were conferred *in absentia*, and Prof. Nesmeyanov, rector of the University of Moscow and well known for his researches on organo-metallic compounds, in accepting them for his absent Russian colleagues, replied for the recipients.

The formal ceremonies of the sexcentenary celebrations terminated on April 9 at the Vladislav Hall. The six deans of the University gave brief accounts of the history and work of their respective faculties, and Prof. Bydžovský concluded by thanking those whose work and presence had made the occasion such a success. It had been a landmark in the history of the University and of Czechoslovak learning, and had served to strengthen the bonds of friendship between men of science and culture throughout the world.

At the Clementinum and in the Industrial Art Museum there were exhibitions of books, historic documents, *incunabulæ*, paintings and other objects that are rarely available for the public to see. These included various fourteenth century Bulls and decrees relating to the University, the original Kutná Hora decree dated 1409 of Wenceslas IV, a letter from the rector in 1414 protesting against the burning of books, fourteenth-century registers of students, the matriculation lists for 1372–73 and a manuscript written by Hus as rector in 1401–2.

The "Letter of Majesty" extracted from Rudolf II in 1609 which conferred greater liberty on the University was on view, and showed the scissor cuts of Ferdinand II, who revoked it in 1620. There were many early scientific tracts, diplomas, and early printed books. Most of the portraits were of early scholars and naturalists such as Mikan, Bohadsch, Procházka, Marcus Marci, Bolzano, Krombholz, the Presls, Dobrovksý and Šafařík. Tycho Brahe's portrait, sextant and "Tabulæ sinuum" were among the other interesting objects on view. The books included the earliest Czech works in science and mathematics, the 1879 edition of Goll's "Development of the English Parliament", which is said to have greatly influenced T. G. Masaryk, and Beneš's 1909 dissertation for his degree ("Developments of Political Individualism in the History of Modern Philosophy"). Among the historical works was the manuscript of Bohuslav Balbin, that waited a century before it was printed as "Bohemia Docta" in 1780. Another curiosity was the 1793 bilingual announcement of Pelcl's lectures (the first to be given in Czech since 1620).

The informal arrangements that followed the official proceedings included excursions to Lány (to see the simple but impressive tomb of President Masaryk and his son, Dr. Jan Masaryk), Lidice, Karlštein (the castle built by Charles IV as a retreat from the cares of State and for the custody of the crown jewels), Kutná Hora and Hradec Králové. It was at Kutná Hora, a medieval mining town and royal seat, in 1409 that Charles's son, Wenceslas IV, signed the famous decree expressly laying down the Czech character of the Charles University. Receptions in connexion with the celebrations were given by the Rector of the Charles University, the Lord Mayor of Prague and by the Minister of Foreign Affairs, Mr. V. Clementis. Mr. Clementis received no less than nine hundred guests in the large reception halls of the Czernin Palace that serves for the Foreign Ministry to-day. A special performance of Smetana's opera "The Bartered Bride" was given at the National Theatre, and the students also arranged some festivities, one anachronistic tableau representing Charles IV riding on a motor-cycle. Unfortunately the strain of the celebrations told upon the sixty-eight years old rector, Prof. Bydžovský, who was taken to hospital two days after the ceremonies ended.

OBITUARIES

Sir Franklin Sibly, K.B.E.

The life of the late Sir Franklin Sibly was notable as the triumph of a brilliant mind over physical frailty. After an almost precocious career as a student (he obtained the degree of D.Sc. at the age of twenty-five), he became a teacher and worker in geology. He seemed set for the life of an active academic geologist, and the work he accomplished in the ten years of this phase placed him in the front rank. But in 1920 his appointment as principal of University College, Swansea, brought out his latent genius for administration, and during the last twenty-six years of his active life he became successively vice-chancellor of the University of Wales, principal of the University of London and vice-chancellor of the University of Reading. Such responsibilities might well have filled a normal life, especially since their holder was by no means physically robust; but from 1929 until 1946 he held, often concurrently, a series of administrative positions to which he brought qualities of sagacity and geniality beyond the ordinary.

There is no room in this brief account for even a bare enumeration of Sir Franklin's manifold activities; but a few aspects of his achievements may be selected to show something of his qualities. His published geological work is concerned chiefly with the Carboniferous rocks of the Mendip and Forest of Dean districts. After nearly thirty years, his papers still stand as fundamental clarifications of these complex areas—they are by way of becoming classics.

As first principal of University College, Swansea, he achieved a vast amount of constructive administrative work that gave a firm foundation for future developments. As second vice-chancellor of the University of Reading he had further opportunities for building tradition. It was in the last-named office that he spent the longest single period of his life (1929–46), and his colleagues rejoice to realize that the wisdom and friendliness that they found in him were reciprocated in his happiness among them.

In the wider academic sphere, Sir Franklin was chairman of the Executive Committee of the Universities Bureau of the British Empire from 1929 until 1934. Later (1938–43) he held a similar position in the Committee of Vice-Chancellors and Principals, and during the difficult war years exercised a guiding influence on the policy of all British universities.

As a member of the Advisory Council of the Department of Scientific and Industrial Research (for a cumulative period of ten years) he was largely instrumental in devising the conditions of award of the Department's scholarships—now widely recognized as a model for all such schemes. For thirteen years he happily combined both phases of his genius as chairman of the Geological Survey Board.

The honorary degree of LL.D. was conferred on him by the Universities of Bristol, Wales and Liverpool. He was knighted in 1938 and received the K.B.E. in 1943.

In spite of his notable services to British science and also his administrative skill, the abiding memory for those who knew him is one of friendship. His good humour and understanding sympathy were never lacking, even when failing health might have excused their lapse. He improved on the recommendation to be all things to all men by being consistently himself to all; everyone who worked with him or for him knew him for a friend.

H. L. Hawkins

Mr. G. S. W. Marlow

George Stanley Withers Marlow, whose death occurred on March 5, was born in 1889, and educated at New College Choir School, Oxford, and King's College, University of London. He graduated B.Sc. in 1909, and the next year obtained his associateship of the Institute of Chemistry, taking as his special subject, food and drugs. The F.I.C. (now F.R.I.C.) followed in 1913. For a couple of years after graduating, he was assistant to Mr. E. Hinks, public analyst for the County of Surrey. In 1911, he joined the staff of the Government Chemist, where he remained until 1919, when he became assistant secretary of the Institute of Chemistry. After six years there, he left to become personal assistant to Mr. W. J. U. Woolcock, general manager of the Association of British Chemical Manufacturers. Meanwhile, in 1923, he had been called to the Bar, and decided to practise in 1927. He was a member of Gray's Inn, and pupil to the late Mr. W. Trevor Watson, K.C. He acted in such cases of chemical patents as arose, his first being the application of Boots Cash Chemists, Ltd., to revoke Sharp and Dohme in the matter of hexyl resorcinol.

In 1926, however, an event happened in Marlow's life which was to transform its pattern to a considerable extent and provide him with a task after his own heart. This was the suggestion by the Council of the Faraday Society that he should succeed the late Mr. F. S. Spiers as general secretary, and take over the management of its affairs, including the editorship of the *Transactions*. Marlow accepted, and in so doing initiated a tenure of some twenty-two years, during which the Society has advanced from strength to strength, largely due to his unflagging efforts, wisdom and guidance. Marlow lived for the Faraday Society, and his devotion to it knew no bounds.

The General Discussions, which have always been the Society's major activity, were a feature before Marlow took charge; but he managed to give them further weight and authority, at the same time enhancing their hospitable and social character. For more than a couple of decades, he always had at least one Discussion ahead, before he was clear of the one behind, and lived, scheming and planning, to make each one an individual success. He would journey to universities all over the country in search of appropriate places at which to meet, and no vice-chancellor or principal was safe from his clutches in his efforts to obtain accommodation and comfortable surroundings for the participants. On these occasions, the guest-night dinners were distinguished, the secretary radiating good-fellowship throughout the evening. During one of these General Discussions, Prof. P. Debye wished to give an impromptu demonstration of the properties of a dipole. Marlow, as to the manner born, quietly handed him a cigar for the purpose. Foreign guests were his special concern; nobody was permitted to worry for a moment on account of lost luggage, money, passports, or even relations. The secretary produced them all, safe and sound, with that engaging smile of his, as if nothing had happened.

So the years went on; the *Transactions* increased in bulk, and—during the War—no less an anxiety for Marlow, who remained editor until 1946. But above all, they increased in quality until to-day they stand unrivalled in their own field. Marlow worked his referees hard, and they responded.

By nature, Marlow was ever ready to do people or causes a good turn, and this led to his being much in request just perhaps upon the periphery of his normal avocations. He served the Royal Institution as secretary of the Visitors' Committee, and was a manager at the time of his death. His magnanimous but firm reaction to the abortive proposal of that body to revise its by-laws somewhat drastically was characteristic. He was prepared for change, where change was necessary, but not for ruthless pruning of those noble, rounded phrases of which we shall never see the like again. He delighted in them, and all for which they stood.

In recent years, Marlow took much interest in the Society for Visiting Scientists, and would often be found at its headquarters, lending a friendly hand with whatever was afoot. But in all this, the Faraday Society was Marlow, and Marlow was the Faraday Society; wholly impossible was it to think of one without the other. And that, alas, is what in practice we are obliged to do now. Nobody is irreplaceable, but Marlow's life-line had been approaching the asymptote of indispensability for a number of years, and with its end the margin of contact is seen to be exceptionally narrow.

ERIC K. RIDEAL
F. I. G. RAWLINS

Prof. Selig Hecht

THE death of Prof. Selig Hecht in New York on September 18, 1947, at the age of fifty-five, deprives the physiology of vision of one of its most outstanding workers. Hecht was born in Austria and was brought to the United States as a child. He studied and worked in the United States, in England, Germany and Italy. After a broad biological training, he devoted his life to the study of the mechanisms of vision, considered as a branch of general physiology. He became professor of biophysics at Columbia University and made his laboratory an international centre of visual research.

Hecht's main work was concerned with the investigation of the many visual functions in man, such as dark-adaptation, intensity discrimination, acuity and colour vision. He had begun, however, by studying the reaction to light of simple organisms, such as the clam *Mya arenaria*, and he carried out some remarkable experiments on the vision of insects. He also worked on the photochemistry of visual purple. All these researches were inter-connected comparative studies trying to reach the principles of visual response. Hecht's method was quantitative and his experimental standards exacting. The introduction to his lucidly written papers was often a concise but critical synthesis of a mass of literature on the subject, including the early classical work, of which he had an exhaustive knowledge. His aim, he said, was not to add to, but rather to subtract from, the literature on vision.

The leading idea of Hecht's research was that the very first reactions which take place between light and the photo-receptors are bound to determine to a large extent the characteristics of the visual response. He, therefore concentrated his attention on these reactions, because they were easier to study than more central processes, especially those in the brain. One result of his work was to establish beyond doubt the duplex nature of the mechanisms of the human retina, corresponding to the division of its photoreceptors into rods and cones. He clarified the relation between the rod visibility curve and the absorption of visual purple, and he devoted much attention to the photo-chemistry and kinetics of the reactions initiated by light in the receptors, introducing the notion of the 'stationary state' of excitation.

Just before the War, Hecht took up with characteristic thoroughness the problem of the minimum energy necessary for vision. He found that a man can see a source of light which delivers to his retina only six quanta or so, absorbed by the visual purple of the rods. Stimuli consisting of such small quantities of light have unique properties; for example, they undergo from one trial to the next uncontrollable variations, which are related to the uncertainty of seeing observed in the measurements.

Hecht worked strenuously on visual research for the American Forces during the War. As he was preparing to return to the study of quantum problems, he died suddenly of a coronary thrombosis.

A painter and a man of discriminating taste, Hecht had many interests. A well-done piece of scientific work would fill him with delight. It was both as a scientific man and as an artist that, for example, he admired Schultze's pioneer work and his drawings of the retina. He was a brilliant lecturer and expositor —he wrote a book entitled "Explaining the Atom". The lack of synthesis discernible in present-day knowledge and teaching perturbed him, and he took an active interest in all the human implications of science. He dealt with persons and ideas on the basis of their intrinsic worth and was always ready to give genuine help, so that he won the affection of all those working with him. Selig Hecht will be mourned by many friends and colleagues throughout the world, and his death is a great loss to science.

M. H. PIRENNE

Prof. M. C. Potter

PROF. N. S. ALEXANDER, Physics Department, Raffles College, Singapore, writes: An interesting link with Victorian science ends with the death at the age of nearly ninety of Prof. M. C. Potter [see *Nature*, April 17, p. 590]. Some time ago, Prof. Potter presented me with a copy of "A Treatise on Hydrostatics and Hydrodynamics" written by his uncle, Dr. Richard Potter, formerly professor of natural philosophy in University College, London. Part 2 of this work was completed in 1880, the author being then eighty-one years of age, and was published by M. C. Potter in 1887. These two lives between them span nearly 150 years.

Richard Potter's book takes one back into the 'caloric' controversy, and his views are sufficiently shown by the following quotations: (*a*) referring among others to Rumford's experiments, "The whole three cases are mills for grinding atmospheric air under pressure with the production of heat from its condensation"; (*b*) "In Mr. Joule's experiments which were performed in air, the effect rising from its presence is entirely neglected, and the phenomena of heat being attributed to the mechanical force applied alone . . . the conclusions drawn from them are erroneous"; (*c*) "c/c' (the ratio of the principal specific heats of a gas) $= 1$ nearly for small values of δ (the condensation), and the *instantaneous* change in specific heat of a gas is insensible for small rarefactions and condensations. After some time which has not yet been ascertained, the change in capacity for caloric is completed, and the temperature has changed considerably."

Prof. M. C. Potter had clearly been influenced by these views, and up to the time of his death was endeavouring to show that the usual statement of the First Law of Thermodynamics is incomplete. He had obtained some quite interesting results on electrical effects accompanying various chemical and mechanical changes, and believed that the neglect of these effects constituted a fatal objection to the experimental basis of the First Law. He frequently used to remark, "Joule will have to go". Perhaps it would not be too much to refer to Dr. Potter as the last of the calorists.

We regret to announce the following deaths:

Prof. S. C. Brooks, professor of zoology in the University of California, Berkeley, known for his work on the biological effects of radiations and the permeability of cells, on April 25, aged fifty-nine.

Dr. H. W. Richmond, F.R.S., president during 1920–22 of the London Mathematical Society, on April 22, aged eighty-four.

NEWS and VIEWS

Archæology in the University of London: Dr. R. E. Mortimer Wheeler

Archæologists will be pleased to learn that Dr. R. E. Mortimer Wheeler has accepted a chair in the University of London. He shares with Sir Cyril Fox the distinction of being one of the most stimulating of archæological exponents in Great Britain. Dr. Wheeler has had a distinguished career both in archæology and in the army. For a time he was director of the National Museum of Wales, and then he became head of the London Museum. It was during this London Museum period that Mrs. Wheeler died; to her splendid personality and experienced help he owed much both personally and archæologically; as, for example, when he set about the founding of the Archæological Institute, which is housed in Regent's Park. A member of the Territorial Army, the War sent him to Africa with the 8th Army and Italy with the 5th, where he ended up as one of the small band of non-professional soldiers who achieved the rank of brigadier. Recently, he has been director-general of archæology in India. He has been president of innumerable archæological bodies and has served on the Royal Commission on Historical Monuments. Dr. Wheeler has undertaken not a few archæological excavations, the most important, perhaps, having been that at Maiden Castle, and has published extensively on various subjects. His book "Prehistoric and Roman Wales" is a standard work on early times in that country. He has also written on the ancient sites at Lydney and Verulamium. His influence will greatly strengthen the growing school of archæology in the University of London, and we may look forward to many interesting results from excavations undertaken by him.

Institution of Metallurgists: Dr. A. D. Merriman

Dr. Arthur D. Merriman has been appointed to the full-time post of registrar-secretary of the Institution of Metallurgists. Dr. Merriman's initial training was in physics, mathematics and chemistry, and he has had some twenty years experience in academic fields, including the post of principal of the County Technical School, Wallsend-on-Tyne, 1926–38. During the early part of the Second World War, he served with the Directorate of Scientific Research, Ministry of Supply, and was the senior member of a group of scientific men and engineers dealing with bomb disposal problems; for his personal courage in emergency situations he was awarded the George Cross. From 1941 until 1944 he was scientific adviser to the Commander-in-Chief, Middle East, and in 1944 was appointed to a special intelligence assignment in the U.S.S.R., followed by similar work in north-west Europe and Germany. Since then he has been a principal scientific officer (technical intelligence) at the Armaments Design Department, Ministry of Supply. Dr. Merriman succeeds Dr. Harold Moore, the Institution's first president, who has been serving as registrar, and Mr. K. Headlam-Morley, secretary of the Iron and Steel Institute, who has acted as secretary of the Institution. Office accommodation will continue to be provided for the Institution at 4 Grosvenor Gardens, London, S.W.1.

British Council Science Department: Mr. E. Bolton King

Mr. E. Bolton King, formerly managing director of the Oxford Instrument Co. and during the War a member of the Ministry of Supply Rocket Team, has been appointed director of the Science Department of the British Council. Educated at Warwick School and Balliol College, Oxford, where he was a mathematical exhibitioner, he obtained first-class honours in Physics Finals. He was elected to a research studentship at Christ Church, Oxford, and carried out research at the Clarendon Laboratory, largely on photo-electricity. Later he formed the Oxford Instrument Co. Early in the War he joined the Ministry of Supply Rocket Team under Sir Alwyn Crow and was engaged on rocket development, with special emphasis on proximity fuses, investigation of the performance of British and enemy rocket weapons in the Mediterranean theatre and liaison with rocket development in the United States, where he was an assistant director of the British Commonwealth Scientific Office. At the end of the War he went to Germany in connexion with the British firings of the V-2 rocket and became superintendent of the Ministry of Supply Establishment, Cuxhaven; since then he has been in the Directorate of Guided Weapons of the Ministry of Supply.

Exhibition of the Development of Lighting

A special exhibition, "Darkness into Daylight", was opened at the Science Museum, London, on April 29 to illustrate the development of lighting from the earliest times to the present day. A historical section, in which the Victoria and Albert Museum has co-operated, shows vividly by means of examples and dioramas the growth of lighting until the lamps of Swan in 1878 and Edison in 1879 marked the beginning of an era of intensive research culminating in modern discharge lamps. Among these, the xenon arc, which has so far been confined to laboratory demonstrations, is exhibited, together with micro-second flash tubes and compact source lamps. The history of fluorescence is covered by an attractive series of demonstrations, and its applications, including that of mine lighting, are also shown. Applications of lighting to the theatre, television, roads and medical uses include many interesting demonstrations, while good lighting in the home is shown by a full-scale sequence exhibit called the "Room of To-morrow". The Exhibition will remain open until the end of September.

Davy Faraday Exhibition in Paris

An exhibition devoted to the life and work of Davy and Faraday has been arranged at the Palais de la Découverte in Paris (which operates in association with the University of Paris) with the close collaboration and support of the Royal Institution, the Institution of Electrical Engineers, and the Science Museum, and will remain open until July. The managers of the Royal Institution have lent a number of the relics of Michael Faraday from their collection, as, for example, some of the original apparatus used by him in his experiments and pieces of his laboratory and office equipment. The Council of the Institution of Electrical Engineers has lent a number of Faraday manuscripts and letters and the full-sized reproduction of the statue of Faraday, the original of which stands on the main staircase in the Royal Institution, which dominated the Faraday Centenary Exhibition at the Albert Hall, London, in 1931. The General Post Office has provided an ingenious working section of an automatic telephone exchange, recently shown at Radiolympia. With the collaboration of the British Council, arrangements have been made for a number of lectures to be delivered at the Exhibition by British men of science and engineers on the life and work of Davy and Faraday.

British Institute of Management

Presiding at the first meeting of the British Institute of Management on April 21, Sir Charles Renold, chairman of the Institute, said that the Institute would need the goodwill, active interest and co-operation of all who exercised the major responsibilities of management. Management, he emphasized, is not concerned with party politics or with theories of ownership, and it is with the principles which apply to all industries and with the problems arising in their application that the Institute is concerned. A national drive for better management would be developed along three main lines: by the compilation of knowledge about management; by promoting education and training facilities; and by the dissemination of knowledge about management. Speaking of the necessary research, Sir Charles hopes that the Institute will have the co-operation of the universities and other bodies, including the trade unions, and he pointed out that there is little or no guiding experience in Great Britain for some of the problems of management presented by the vast scale of some of the nationalized industries. The Institute has already initiated discussions with university authorities on the preparation at the university-level of men for management, and is also studying training for foremen and supervisors. Sir Stafford Cripps, who, as well as Sir Frederick Bain and Miss Florence Hancock, chairman of the Trades Union Congress, also spoke, emphasized the importance of the Institute being wholly free from Government interference and from concern with party politics. While providing a grant-in-aid, the Government is in no way attempting to control expenditure within the broad purposes agreed. The failure of so many production units to attain the high standards of efficiency set by the most skilled and enlightened managements is a cause of many of the present economic difficulties of Britain; but in spite of the great importance of the technical side, the first and overriding requirement is the creation of an atmosphere of trust. Only in that atmosphere can we secure the co-operation of those working in the factories in the difficult adjustments which the new techniques of production often involve.

British Association: Brighton Meeting

The British Association has now issued a preliminary programme of the annual meeting to be held in Brighton during September 8–15, with Sir Henry Tizard as president. At Dundee last year 3,300 people attended the first of the annual meetings to be held after the outbreak of war in 1939, and the theme of the meeting was the conversion of science from the destructive uses of war to the constructive uses of peace. The programme for the Brighton meeting is again topical and of wide general interest. Among the topics to be discussed are: achievements of X-ray analysis; newer metals and alloys in industry; geology to-day and to-morrow; biology in schools; Colonial development; movements of population in the Commonwealth; the metric system; building materials; human blood groups; colour vision; changing aspects of nutrition; selection of university students; problems of old age; aspects of world education; administrator and teacher; maintenance of world food supply; forestry and the community. The programme can be obtained from the Secretary of the Association, Burlington House, Piccadilly, London, W.1.

The presidents of the various sections are as follow: (A) *Mathematics and Physics:* Sir Lawrence Bragg; (B) *Chemistry:* Prof. John Read; (C) *Geology:* Dr. A. E. Trueman; (D) *Zoology:* Prof. H. Graham Cannon; (E) *Geography:* Lord Rennell of Rodd; (F) *Economics:* Sir Hubert Henderson; (G) *Engineering:* Prof. T. R. Cave-Browne-Cave; (H) *Anthropology and Archæology:* Mr. R. U. Sayce; (I) *Physiology:* Prof. H. Hartridge; (J) *Psychology:* Prof. A. Rex Knight; (K) *Botany:* Prof. J. R. Matthews; (L) *Education:* Mr. O. Lester Smith; (M) *Agriculture:* Dr. G. Scott Robertson; *Conference of Delegates of Corresponding Societies:* Prof. H. J. Fleure.

Colonial Microbiological Research Institute, Trinidad

Acting on a recommendation of Sir Robert Robinson and Prof. J. L. Simonsen, who paid a visit to the Caribbean in 1944, the Colonial Products Research Council decided to erect in Port of Spain, Trinidad, a Colonial Microbiological Research Institute. This Institute, of which Dr. A. C. Thaysen, formerly of the Chemical Research Laboratory, Teddington, is the director, will be opened officially on July 5 by Lord Hankey, chairman of the Colonial Products Research Council. Invitations to attend the opening have been sent to Canada, the United States, the Caribbean Commission, and to a number of South American Republics. The opening will be followed on the Tuesday and Wednesday by scientific meetings.

Anti-Pernicious Anæmia Factor

Twenty-two years ago, Minot and Murphy postulated the presence in liver of a factor effective against pernicious anæmia, and many attempts at its isolation have been made. The long quest now seems to be nearing its end with the independent appearance within a week of two papers, from the United States and Britain, announcing the isolation of red substances having extremely high potency. The American workers (E. L. Rickes, N. G. Brink, F. R. Koniuszy, T. R. Wood and K. Folkers, *Science*, **107**, 396; 1948) describe crystalline material effective in a single dose of some 15 µgm., that is, with roughly two thousand times the hæmatopoietic potency of folic acid. Dr. Lester Smith (*Nature*, **161**, 638; April 24, 1948) does not appear to have taken the purification so far but has separated two different red pigments, both clinically active. These may turn out to be peptide conjugates of this crystalline substance. He gives more information about the properties of his materials than do the Americans, including a value of approximately 3,000 for the molecular weight. The Americans were assisted in their fractionation by a microbiological assay method using *L. lactis* Dorner. The British work depended on clinical assays, of which more than eighty were carried out, and on the red colour. It also established the important fact that the highly purified red material, unlike folic acid, is effective against subacute combined degeneration of the spinal cord. The crystalline substance, for which the Americans suggest the rather unsatisfactory name 'vitamin B_{12}', is remarkably potent, being effective at a daily dose of about 1 µgm. only. A rough calculation indicates that it would require at least twenty tons of liver to yield 1 gm. of crystals. This is in itself sufficient explanation of the fact that these advances have come not from academic institutions but from two industrial laboratories, namely, those of Merck and Co., Inc., Rahway, New Jersey, and Glaxo Laboratories, Ltd., Greenford, Middlesex.

Plant Pathology at the Rothamsted Experimental Station

A useful report by F. C. Bawden from the Department of Plant Pathology and Section of Biochemistry (Rothamsted Experimental Station, Harpenden, 1947. 1*s*. net) covering the years 1939–45 provides an informative summary of certain aspects of research in mycology, plant virus diseases and related biochemical problems. Before 1939, virus research in this Department dealt with insect vectors, the cytology of infected plants, purification of the virus, and the chemical, physical and serological properties of viruses. This work has been continued; but, in addition, much field work on factors affecting the rate of spread of virus diseases in potato and sugar beet has been undertaken. Mycological work has been concentrated largely on the study of soil-borne fungi, the control of which constitutes a major challenge to plant pathology. *Ophiobolus graminis*, *Fusarium* spp., *Plasmodiophora brassicæ*, *Cercosporella herpotrichoides* and *Helicobasidium purpureum* are the disease-producing fungi which have received most attention. The Section of Biochemistry was established in 1940, under the direction of N. W. Pirie. It was originally an offshoot of the Plant Pathology Department, but has now become separate as the work has extended. Work on purification of virus extracts raised some problems with plant enzymes and other systems, which now form an important theme of work in the Section. Most of the published work of the Department and Section has been reviewed in these columns from time to time; the collected accounts in this report will be of value to teachers, advisory officers and others who require a summary of published literature, with an overall digest of its significance.

Pregnancy Test using the Male Toad

Mainini has described (*Semana Medica*, **64**, 337, March 1947) a pregnancy test in which, following injection of pregnancy urine into the male toad (*Bufo arenarum* Hensel), liberation of spermatozoa into the urinary bladder occurs within three hours; the same animal can be used again after five days. Drs. Octavio Rodrigues Lima and Oswaldo Gelli Pereira, of the Obstetrical Clinic, Medical School of Rio de Janeiro, University of Brazil, state in a communication submitted to the Editors that they have confirmed this work, using as test animal the male toad (*Bufo marinus*), as the species used by Mainini was not available to them. Using standard chorionic gonadotrophin (supplied by Organon), they have found that 20 I.U. produced a positive reaction in all of eight animals within an hour. Doses above this level invariably produced a positive reaction within an hour, even if the animals were kept at a low temperature in a state of torpidity (9° C.). Doses below 20 I.U. did not produce positive results within three hours (twenty animals). Œstrone, progesterone, water and saline gave no positive results. Sixty tests were carried out with the urine of amenorrhœic women. Positive results were found between half an hour and two hours, and were confirmed clinically in all cases. The test appears to be simple, economical and reliable.

High-Vacuum Equipment

A booklet issued recently by Messrs. W. Edwards and Co. (London), Ltd., Kangley Bridge Road, London, S.E.26, specialists in the manufacture and provision of high-vacuum equipment since their formation twenty-five years ago, describes briefly the range of products now available. High-vacuum processes are no longer of interest solely to the specialist, for in recent years there has been an astonishing growth in laboratory and industrial applications of high-vacuum technique; hence, in addition to a wide range of the essential components of any vacuum system (rotary backing pumps, diffusion pumps, vacuum measuring instruments, and accessories), complete vacuum plants, combined mobile units, and vacuum pipe-line units, suitable for schools, laboratories or works, are now available. Special vacuum plants listed include: vacuum coating equipment, for depositing thin films of precious and other metals, alloys and non-metallic materials on metallic and non-metallic bases by the evaporation or cathodic sputtering techniques; electron diffraction equipment, suitable for the investigation of surface structure; vacuum sublimation and centrifugal freeze-drying equipment, designed specially for the production of ampoule quantities of dried pharmaceutical and biological materials. Developed in conjunction with Dr. R. I. N. Greaves, this freeze-drying plant utilizes his special technique, consisting of centrifuging *in vacuo* the material to be dried, whereby rapid freezing and sublimation results without frothing, a process which Dr. Greaves successfully employed for his work on blood plasma drying during the War and which has already been described in these columns (*Nature*, 153, 485; 1945).

World Magnetic Data

WITH reference to the article "The Earth's Surface Magnetic Field and its Secular Change" by Prof. S. Chapman in *Nature* of January 31, Commander Elliott B. Roberts, chief of the Division of Geomagnetism and Seismology, U.S. Coast and Geodetic Survey, Department of Commerce, Washington 25, writes: "The Department of Terrestrial Magnetism of the Carnegie Institution of Washington adopted a change of policy after the accomplishment of the monumental magnetic study culminating in the isomagnetic chart series for 1945.0 and publication 578. Routine work in magnetic surveying and compilation of isomagnetic charts will no longer be performed by the Department, which will henceforth restrict itself to experimental and theoretical scientific researches. The Coast and Geodetic Survey has assumed the function, in addition to its normal work of magnetic field surveys in the United States, of collecting all available magnetic field and observatory data from world-wide sources. It is intended to maintain a national reference library of such data for future American use in connexion with the compilation of world isomagnetic charts. The Bureau will continue to compile United States charts on its own account, and, by arrangement with the Hydrographic Office, United States Navy, will henceforth compile world isomagnetic charts, in editions successive to the 1945.0 series. The Bureau solicits magnetic data and copies of isomagnetic charts from all world-wide sources and will undertake in exchange to furnish any required data of American origin."

The Museum in Education

THE Bulletin of the Cleveland Museum of Natural History (*The Explorer*, No. 93, Winter, 1948) contains interesting information about the way in which the Museum's exhibits are put to effective use as part of a general educational campaign. A caravan has been converted into a travelling museum and fitted out with exhibitions to suit the season of the year and the various types of audiences. The "Traveling Trailside Museum" is towed out to schools, hospitals and other organisations, where the contents are exhibited and usually explained in a supporting talk by one of the Museum staff. This travelling museum is greatly in demand and is performing an educational function which brings great credit to its sponsors. Another feature of the educational work of this Museum are the weekly walks led by one of the staff and which are well attended by members of the public. The walks are supported by exhibitions at the Museum depicting local natural history at the time of the walks.

International Council of Scientific Unions

THE report of the Executive Committee of the International Council of Scientific Unions, July 1947 (London: Cambridge Univ. Press. Pp. viii+79), affords the usual handy reference to the activities and personnel of the Unions, the present report including, moreover, the statutes of the newly formed International Unions of Crystallography, of Geodesy and Geophysics, of Biological Sciences, of Theoretical and Applied Mechanics, and of History of the Sciences, as well as the revised statutes of the International Union of Geodesy and Geophysics. The most important feature of the year was the conclusion of a definitive agreement with the United Nations Educational, Scientific and Cultural Organisation. The text of this agreement is appended to the report, which also includes details of grants made by the Organisation for the year 1947. The Organisation has undertaken to give attention to the reorganisation of a scientific inquiry into the causes of international tension and the methods of overcoming them, and to take positive action to forward international scientific organisation for research and the development of free exchange of scientific information.

Conference on Modern Applications of Liquid Fuels

THE Institute of Petroleum and the Institute of Fuel are to hold a joint conference on "Modern Applications of Liquid Fuels" in the University of Birmingham during September 21–23, together with an exhibition of items related to the subjects on the programme. The general scope of the Conference will be indicated in an opening address on "The Place of Liquid Fuel in the British Economy". Separate sessions, each of 2½ hours, will then be devoted to the following subjects: Diesel engines for power generation and railway traction; oil for gas making; gas turbines for land and marine power purposes; agricultural drying processes; and fuel oil in the steel, metal, glass and ceramic industries; there will also be an evening lecture on domestic heating. The fifteen authoritative papers, to be presented at the Conference in summary form, will be printed in full and issued, bound in one volume, one month before the Conference. Inquiries in connexion with the Conference should be sent to the Secretary, Institute of Fuel, 18 Devonshire Street, London, W.1.

Biography of the late Sir James Jeans

PROF. E. A. MILNE, F.R.S., 19 Northmoor Road, Oxford, states that he is engaged upon a biography of the late Sir James Jeans, to be published by the Cambridge University Press. If any readers of *Nature* have in their possession letters or papers of particular interest written by Sir James Jeans, Prof. Milne would be grateful for their loan.

The Night Sky in May

NEW moon occurs on May 9d. 02h. 30m., U.T., and full moon on May 23d. 00h. 37m. The following conjunctions with the moon take place: May 10d. 03h., Mercury 0·06° S.; May 12d. 10h., Venus 0·1° S.; May 15d. 08h., Saturn 4° S.; May 16d. 05h., Mars 4° S.; May 24d. 23h., Jupiter 4° N. In the early part of the month, Mercury is too close to the sun to be seen, but it sets at 21h. 25m. on May 15 and at 22h. on May 31, nearly two hours after sunset, and can be seen in the western sky. The planet is in greatest easterly elongation on May 29. Venus is conspicuous in the western sky, setting at 23h. 42m., 23h. 31m., and 22h. 40m., on May 1, 15 and 31, respectively, and attains its greatest brilliancy on May 18 when 0·305 of the illuminated disk is visible, its stellar magnitude then being − 4·2. Mars and Saturn are conspicuous in the constellations of Leo and Cancer, respectively, and can be observed during the earlier hours of the night, neither planet setting until after midnight. Jupiter, in the constellation of Sagittarius, rises at 23h. 30m., 22h. 27m. and 21h. 22m. at the beginning, middle and end of the month, respectively. No occultations of stars brighter than magnitude 6 take place during May. An annular eclipse of the sun occurs on May 8–9, invisible at Greenwich.

Magnetic Observations and Thermometry in the Region of Millidegrees Absolute

It is usual to characterize the very low temperatures obtainable by adiabatic demagnetization by

$$T^* = C dH/dM,$$

the temperature which would correspond to the magnetic susceptibility dM/dH if the Curie law

$$M = CH/T$$

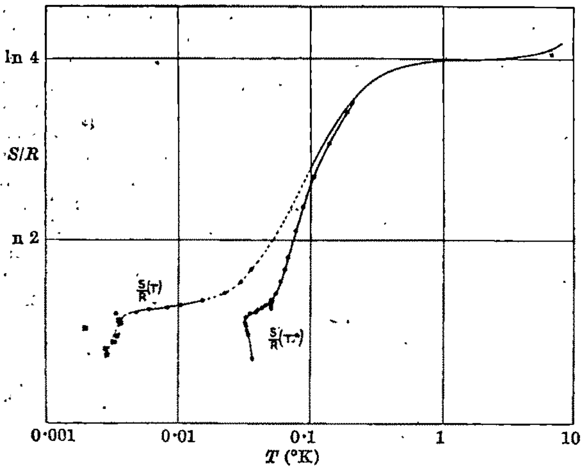
were valid. As, however, the lowest limit of the temperatures obtained is determined by deviations from the Curie law, considerable differences between T^* and the real temperature must be expected there. The lowest value of T^* so far reported is 4·4 millidegrees absolute in a mixed crystal of chromium potassium alum and aluminium potassium alum[1].

Experimenting with a spherical single crystal of chromium potassium alum, we confirmed the observation of Kürti, Lainé and Simon[2] that the susceptibility χ has a maximum below which a feeble magnetic hysteresis occurs. The magnetic behaviour at these temperatures is very similar to that of anhydrous salts like cobalt chloride and bromide and nickel chloride at much higher temperatures[3]. The minimum of T^* corresponding to the maximum of χ was 32 millidegrees. In the accompanying diagram the right-hand curve gives the entropy S as a function of T^* as obtained by adiabatic quasi-static demagnetizations. From a T^* about 60 millidegrees downward, paramagnetic losses have been measured which between 225 and 525 cycles seem to vary slightly more slowly than in proportion to ν^2 (see ref. 4).

The width of the hysteresis loop proved to be a useful thermometer at the lowest temperatures. In the intermediate region the paramagnetic loss mentioned may provide a useful thermometer.

We calibrated T^* and the width of the hysteresis loop against the thermodynamic scale of temperature, following suggestions of Keesom[5], Kürti, Lainé and Simon[6] and Casimir, de Haas and de Klerk[7]. Known small amounts of heat ΔQ were supplied to the sphere by electrically measured paramagnetic losses. The thermodynamic temperature is now given by

$$T = \frac{\Delta Q}{\Delta S}.$$



Entropy of $CrK(SO_4)_2.12H_2O$ as a function of T^* (right-hand curve), and as a function of T (left-hand curve). ●, susceptibility thermometer ; ⊡, remanence thermometer

The results lead to the left-hand curve of the diagram, in which the entropy S is given as a function of T. The maximum of the susceptibility occurs at about 5 millidegrees absolute, while the lowest temperature observed is slightly lower than 3 millidegrees. These temperatures are lower than expected, and they are in disagreement with the calculations as well as with the provisional results of gamma-ray heating by Kürti, published by Hebb and Purcell[8]. Gamma-ray heating seems to us a very uncertain way of supplying heat at the lowest temperatures, as a fraction of the absorbed energy may be stored instead of being transmitted as heat to the spin system.

The highest temperature measured accurately was 22 millidegrees. In plotting the curve for higher temperatures, unpublished measurements of Bleaney, kindly placed at our disposal, were used.

At the lowest temperatures a known quantity of heat could also be supplied to the salt by describing a number of hysteresis loops, the surface of which had been determined by a ballistic method. The results were in reasonable agreement with those obtained by the other method of heating ; they have been omitted in the diagram.

The slope of the $S-\ln T$ curve gives the specific heat. It is seen that there is a marked plateau at $S = 0{\cdot}4 R$ corresponding to a low minimum in the specific heat. It is noteworthy that this plateau lies so much lower than $R \ln 2$.

Details of this work will be published in *Physica*.

Radiation Damping and Velocity of Light

In a recent communication, Ferretti and Peierls[1] have applied the theory of radiation damping suggested by Peng and me[2,3] to the problem of the propagation of light. By considering the exchange of excitation energy between two like atoms through emission and absorption of light, they came to the conclusion that, according to this theory, light does not travel with the velocity c. The result must seem surprising for the following reasons : (i) The propagation of light is a property of the vacuum and has nothing to do with the approximation in which the interaction with electrons is treated. (ii) The problem has already been treated by Kikuchi[4] on the grounds of the earlier theory of Weisskopf and Wigner[5], which is a special case of the more general theory quoted above. Kikuchi found the correct velocity of light. (iii) The theory of damping consists of nothing but a *systematic* elimination of the infinite parts of quantum-electrodynamics, a procedure which for special problems has been, and had to be, adopted before in nearly all applications of quantum-electrodynamics, including the theory of Weisskopf–Wigner (which does not mean that this crude procedure yields always exact and correct results. It is particularly to be noted that the avoidance of the infra-red catastrophe rests on the low-energy end of the neglected diverging integrals[6].)

In refs. 2, 3, only the case of collisions between free particles was treated in detail, that is, the case in which all initial and final states belong to the continuous spectrum and have zero line-breadth; and it was mentioned in ref. 3 that the theory reduces essentially to that of Weisskopf and Wigner for the emission of light by atoms in discrete levels. A representation was used in which the probability amplitudes of all states were functions of time. For collisions between free particles, it is permissible, as was done in refs. 2 and 3, to distinguish between states with energies equal to that of the free particles before the collision, namely, E_0, and states with different energies, because the total energy of the system is equal to that of the free particles. However, as Pauli[7] has shown, this distinction is unnecessary; it comes out automatically. For this purpose it is more convenient to consider all processes as a superposition of stationary processes and work with energy representation. The two methods are exactly equivalent, being Fourier transforms of each other. In the stationary method, a variable energy E occurs instead of the time t (as a result of the Fourier transformation), representing the total energy of the system including the interaction. For collisions between free particles this energy is equal to E_0. This will no longer be the case when discrete levels are involved.

When using the equations of the damping theory as they stand (equat. II, III on pp. 245, 247 of ref. 3), Ferretti and Peierls have pointed out an ambiguity arising there when the line-breadth is finite. Indeed, if one distinguishes states within a narrow energy band around E_0, it is not clear how wide this band is to be taken when the line-breadth is finite. Any marking off of such an energy band for a finite line-breadth would be very artificial, and, as was pointed out above, is unnecessary. To resolve the ambiguity, the obvious way is to re-examine the derivation of the equations of the damping theory, without distinguishing between states of equal energy. For this purpose the use of the energy representation is more convenient. This has now been done in collaboration with Dr. S. T. Ma. The result is that the form of the equations III of ref. 3 is the same as before. Only the quantities occurring in these equations, like U_{AO} and the compound matrix elements, appear in a slightly generalized form (a trivial generalization), in that they depend, as was expected, on the variable energy E also, which is now no longer identical with the energy of the initial state E_0.

Transforming to time representation, one obtains he time-dependent equations II of ref. 3 also in exactly the same form as before, provided that $E_0t \gg 1$, an approximation which, of course, always holds. In these equations E no longer occurs. No distinct energy band occurs either, that is, the energy differences of the final states cover the *whole* line-breadth and extend in principle up to infinity, a result which might have been anticipated even without proof. No additional compound matrix elements occur in which a photon ranks as intermediate state.

It should be pointed out that here the same infinite parts of the theory can, and have to be (at the present stage of our knowledge), eliminated as before, and that the same method has been used for this purpose.

The theory of Weisskopf–Wigner results, if one neglects, as one may well do, certain small reaction terms. The case of collisions between free particles and vanishing line-breadth is, of course, also included, with $E = E_0$.

The solution of the equations in question for the problem of the propagation of light is a matter of a few lines of calculation. The result is the one to be expected: Let $b_0(t)$ $b_1(t)$ be the probability amplitudes for the two states: (i) the first atom is excited, the second in the ground state; (ii) first atom in ground state, second atom excited; and let the initial conditions be: $b(0) = 1$, $b_1(0) = 0$. If R is the distance between the two atoms, then $\dot{b}_1(t) = 0$ (and therefore also $b_1(t) = 0$) for any time $t < R/c$. Thus the exchange of excitation energy travels with the correct velocity c. There is no immediate connexion of this problem with that of *Bremsstrahlung* and the infra-red problem.

A full publication together with Dr. Ma is being prepared for the Royal Irish Academy. Considerations in a similar direction have also been carried out by Mr. Hamilton, and I am indebted to him for having sent me his manuscript.

Phase-Angle Determination in X-Ray Crystallography

A. D. BOOTH has suggested[1] that a study of the diffuse reflexions in X-ray diffraction photographs should give information as to the phase-angles of the Bragg reflexions. In particular, in the case of a centro-symmetrical structure, for which the phase-angles of the reflexions are all 0° or 180°, a streak of diffuse reflexion joining two Bragg reflexions would indicate that there can be no change of sign in the structure factor between the Bragg reflexions, and that these two reflexions must therefore have the same phase-angle.

There are, however, two serious theoretical difficulties in this argument. The first is that although the Bragg reflexions from a centro-symmetrical structure must all have phase-angles equal to 0° or 180°, the diffuse reflexions need not, since they are due to *disturbances* in the structure caused by thermal motion, and the disturbed structure need not have a centre of symmetry. Thus the diffuse reflexion may have phase-angles other than 0° or 180°. If the phase-angle changes continuously from 0° to 180° as we go from one Bragg reflexion to another, the intensity need nowhere be zero. In other words, the amplitude of the diffuse reflexion (which is not the same as the structure factor for the unit cell of the structure calculated at a point between two Bragg reflexions, as Booth[1] seems to imply) may be complex; and a quantity can change continuously from real and positive to real and negative without anywhere passing through zero if complex values are possible. In practice the amplitudes and phases of the diffuse reflexions are continually changing as the crystal vibrates, and what is observed is the *mean* intensity.

Secondly, the phase-angle of a reflexion is not an absolute quantity, as is often implied; it depends on the position taken for the origin of the unit cell of the structure. For example, consider a simple cubic structure of the KCl type. If we take the origin at one of the atoms, every reflexion has a phase angle of 0°. If, however, the origin is shifted to a point at the centre of the unit cell considered above (this still gives us a centre of symmetry at the origin), then the phase of the (h,k,l) reflexion is 0° or 180°, according as $(h + k + l)$ is even or odd. This shows that one must treat with caution any general argument leading to the conclusion that two reflexions have the same phase angle, since this conclusion may, in some cases, be meaningless.

Extensive Penetrating Showers

AN investigation has been carried out in which extensive showers selected by a fourfold array of Geiger–Müller counters (each of area ~ 200 cm.^{2}) were used to trigger a cloud chamber of collecting area about 70 cm.^{2}. In addition, the operation of a large single counter tray (area ~ 720 cm.^{2}), shielded by 15 cm. lead on the top (or in part of the work with 16 cm. iron + 10 cm. lead) and surrounded by 8 cm. lead on all sides, in coincidence with the fourfold array was recorded on the chamber photographs by means of an indicator lamp. Thus a density sample of the showers was obtained in the chamber and the probability of the operation of the shielded tray was studied as a function of the number of shower tracks in the corresponding photographs.

The total fourfold shower counting-rate was found to be $2{\cdot}08 \pm 0{\cdot}08$ counts per hour, of which $0{\cdot}345 \pm 0{\cdot}024$ counts per hour were accompanied by penetrating effects under 15 cm. lead, while $0{\cdot}365 \pm 0{\cdot}032$ counts per hour was the rate of penetrating counts under 16 cm. iron + 10 cm. lead.

Following the treatment described by Jánossy and Broadbent[1], we deduce from these data that the average probability that a single shower particle is accompanied by a penetrating event is $k = 0{\cdot}020 \pm 0{\cdot}002$. The result is in good agreement with those of previous workers.

Assuming the density spectrum of extensive showers given by Cocconi[2], Daudin[3] and Clay[4], we were further able to deduce the expected rate of photographs showing a number n of shower particles. The expression for the fraction of the photographs with n tracks is

$$R(n) = \int_0^\infty (1 - e^{-sx})^4 \, e^{-s_1 x} \, \frac{(s_1 x)^n}{n\,!} \, x^{-(\gamma + 1)} dx,$$

where $\gamma = 1{\cdot}5$ is the integral exponent of shower density, and s, s_1 are the collecting areas of each of the fourfold counters and of the cloud chamber respectively. The calculated values are given in column 3 of the table, and are in agreement with the observed numbers (col. 2).

Now using an extension of this analysis to the penetrating part of the shower, we are in a position to compare the fraction of penetrating counts when n shower tracks appear in the cloud chamber photograph, with that to be expected on a specific assumption about the relationship between the probability of the occurrence of a penetrating count and the local density of the extensive showers. We use here the simplest assumption: that the occurrence of a penetrating count in any region of an extensive shower is proportional only to the particle density in that region; in fact, that the constant $k = 0{\cdot}020$ refers not only to the average over all showers but also in detail over the whole range of shower densities important in this experiment. An expression can be deduced for the fraction f of photographs showing n tracks not accompanied by penetrating counts:

$$f = \frac{\int_0^\infty (1 - e^{-sx})^4 \, e^{-s_1 x} \, \frac{(s_1 x)^n}{n\,!} \, e^{-s_2 k x} \, x^{-(\gamma + 1)} dx}{\int_0^\infty (1 - e^{-sx})^4 \, e^{-s_1 x} \, \frac{(s_1 x)^n}{n\,!} \, x^{-(\gamma + 1)} dx},$$

where s_2 is the area of the shielded extension. In the table, values of f calculated using this expression are compared with those observed. It is evident that the assumption made about the distribution of penetrating events throughout the extensive showers represents closely the observed results. The table combines data in which the tray of counters, recording penetrating events, was shielded by 15 cm. lead and by 16 cm. iron + 10 cm. lead. No significant difference was found between these two conditions; the implication of the result will be treated in more detail elsewhere.

No. of particles, n, in the cloud chamber	Total No. of showers		Fraction, f, of showers not accompanied by penetrating count	
	Observed	Calculated	Observed	Calculated
0	805	759	$0{\cdot}87 \pm 0{\cdot}01$	0·91
1	342	366	$0{\cdot}83 \pm 0{\cdot}02$	0·85
2–3	206	222	$0{\cdot}75 \pm 0{\cdot}04$	0·75
4–7	57	68	$0{\cdot}54 \pm 0{\cdot}09$	0·52
$\geqslant 8$	27	22	$0{\cdot}18 \pm 0{\cdot}08$	0·17

I wish here to record my sincere thanks to Prof. Blackett for the encouragement and facilities he has given for conducting this experiment. I am also greatly indebted to Dr. Jánossy for suggesting the problem and helping me in the interpretation of the results, and to Dr. Wilson and Mr. Hamilton for many helpful discussions during the progress of the work.

Mesons of Different Masses

Leprince-Ringuet[1], Powell and co-workers[2], Rochester and Butler[3] and others have found convincing evidence for the existence of mesons with different masses. It seems, therefore, appropriate to emphasize that these experimental facts, which are to my knowledge not yet satisfactorily explained by either of the current meson theories, can be accounted for by a theory I have proposed recently[4]. I have made an attempt here to solve the problem of elementary particles with the help of four-dimensional spaces. My theory involves that electrons, and similarly protons, may exist in instable 'meso-states' as well as in their normal stable state. The theory provides one solution for the meso-state of the electron (meso-electron) and eighty-two solutions for the meso-protons.

The meso-electron has a spin of 1, a magnetic momentum of 1/137 Bohr magneton; its mass can unfortunately not be determined with as much accuracy as was possible for the other elementary particles; however, its value can be given as (250 ± 10) m_e. A neutral meso-electron (neutretto) may also exist, the mass of the latter being only slightly smaller than that of the charged particle.

The meso-protons all have spin $\frac{1}{2}$, and we may divide them into two classes, according to whether the quantum number n is even or odd (see *loc. cit.*, equation 13.1.) The circumstance that the proton belongs in class I renders it plausible that the meso-protons of class I are more stable. The masses and magnetic momenta of the first nine meso-states belonging to class I are indicated in the following table:

No.	n	Mass	Magnetic momentum
1	6	995·8 m_e	0·0037 Bohr magneton
2	8	481·8	0·0096 " "
3	10	217·8	0·0256 " "
4	12	94·6	0·068 " "
5	14	40·1	0·187 " "
6	16	16·7	0·51 " "
7	18	6·85	1·38 " "
8	20	2·77	3·77 " "
9	22	1·12	10·26 " "

The masses of the smaller meso-protons can be derived in good approximation from the equation

$$m_{\text{MP}} = 5720 \frac{\ln 2\,(1 + \exp n/2)}{1 + \exp n/2}.$$

In principle also neutral meso-protons may exist, with configurations similar to that of the neutron; however, on account of their large negative mass-defects, it is very unlikely that they would be found in Nature.

It seems justifiable to identify the meso-electrons with the ordinary mesons to be found in cosmic ray experiments, which according to the best mass determination[5] have a mass of about (240 ± 30) m_e.

From the data collected in the table, we may infer that the first meso-proton might perhaps correspond to the mesons of mass (990 ± 100) m_e observed by Leprince-Ringuet and recently by Rochester and Butler.

The second meso-proton of mass 481·8 m_e may be he π-meson of Powell. This particle could disintegrate, on account of mass, charge and spin conserva-ion, into a meso-proton of mass 217·8 m_e (No. 3, μ-meson of Powell) and a neutretto. Taking the mass of the neutretto as 250 m_e and assuming that the energy corresponding to the mass-difference of 14 m_e emaining after decay is divided between the two decay products in such a way that both of them acquire equal impulses, the kinetic energy of the 217·8 m_e meso-proton will be 3·8 MeV., which would enable the latter to have a range of 500 microns in the photographic emulsion. Powell found for the range of the μ-mesons a value of about 600 microns.

Stressed Aluminium

In the course of an investigation on the behaviour of aluminium (purity 99·998 per cent) after the release of compressional stress to which it had been subjected, it was found that immediately after compression, the lattice parameter was increased, but that in course of time it decreased according to an exponential law, finally reaching a value at room temperature which was higher than the equilibrium value. The rate of recovery increased as the amount of cold work, measured by the percentage reduction in thickness, increased; but the final constant value reached was the same for all the compressions investigated. On annealing the material for a suitable period after it had reached the 'metastable' state, the lattice parameter decreased from the metastable to the true equilibrium value.

Back-reflexion photographs showed that after compression, recrystallization took place, the rate of recrystallization increasing as the percentage amount of compression increased. In case of very severe compression, recrystallization occurred rapidly and immediately after the release of the stress.

Foils made by compressing annealed filings of aluminium did not show the same phenomenon. In this case the increased lattice parameter after compression returned in course of time to the final equilibrium value of the powder from which the foils were produced.

When foreign atoms were introduced into pure aluminium, whether these atoms entered the crystal lattice to form an unsaturated solid solution, or a supersaturated solid solution, that is, an ageing alloy, or whether they were distributed along the grain boundaries, they hindered recrystallization and grain-growth in the compressed material to a marked degree.

Filed and polished surfaces were examined in the light of these results. It was concluded that whereas in a filed surface the lattice parameter of the broken surface crystals changed, finally assuming the lattice parameter of the metastable layer to which they were anchored, in a polished surface the metastable state was reached immediately after polishing, and the crystallites, as in the final state of the filed surface, were in a strained condition. The residual stresses remained until the material was suitably heat-treated. Polishing and filing produce the same metastable state in the surface as severe cold-work produces throughout the body of the material.

These experiments and a discussion of the results will shortly be published in detail.

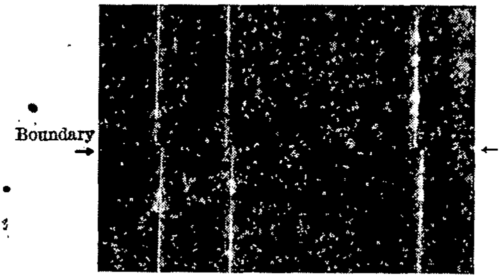
Mechanical Behaviour of Crystal Boundaries in Metals

It has been shown by Kê[1] that differences in the mechanical properties of specimens of aluminium with large and small crystal sizes can be accounted for by assuming that the crystal boundaries behave as viscous liquids. Quantitative experimental evidence of the relative movement of neighbouring crystals in a manner consistent with this hypothesis has so far been lacking.

We have made preliminary experiments on specimens of tin consisting of two crystals and one straight boundary, prepared by a method that has been described previously[2]. The specimens were subjected to tensile loading so arranged as to provide a component of shear stress acting on the boundary. When such a stress is applied at a temperature a few degrees below the melting point, progressive relative shear displacement of the two crystals takes place. This movement is observed by means of fine marks inscribed at right angles to the boundary. The accompanying photograph shows a typical specimen after the application of the stress.



Specimen after application of stress (× 10)

As an indication of the magnitudes involved, the following experimental result may be quoted. With a shear stress component of 590 gm./cm.^{2}, at a temperature of 222° C., the initial rate of relative movement was 7×10^{-4} cm./hr. Experiments so far carried out suggest that the rate of movement diminishes with time. The maximum displacement so far recorded is 0·1 mm.

If the direction of the shear stress is reversed after the rate has diminished to a small value, displacement takes place in the new direction with considerably increased velocity.

There is evidence that lateral movement of the boundary may occur during the process of boundary slip. It is not clear whether this is an inherent part of the process, or whether it is due to some condition not associated with boundary slip.

Internal Stresses in Metals

Heyn pointed out in 1914 that plastic deformation of a metal could result in irregular internal stresses because of the inherent elastic and plastic anisotropy of the grains[1]. With the development of X-ray diffraction methods it has been possible to study the internal stresses by direct experiment. Such X-ray measurements, made by Wood and his co-workers, led, however, to the unexpected result that the internal stresses in a number of metals were by no means irregular, being related in magnitude and direction to the previously applied stress[2]. Iron and carbon steels are typical examples. It was concluded that the stresses were too regular to be explained satisfactorily by the type envisaged by Heyn (which we shall term intergranular stresses).

In a recent communication in *Nature*[3], G. B. Greenough suggests that Wood's results still might be explained by the intergranular stresses if account is taken of the fact that in a given test specimen the X-rays measure the stresses in grains of the same crystallographic orientation only. This property of the X-ray method was pointed out in the above work; but as an explanation of the results it was rejected for the following reason, which further work has confirmed.

Since the intergranular stresses arise from interaction between a grain and its surroundings, the magnitude and direction of the stress experienced by an individual grain will be determined mainly by the relative strength and orientation of its neighbours. The grains of the similarly oriented group which respond to the X-rays are not contiguous but are distributed throughout the specimen. Each grain of the group will be surrounded by a different arrangement of neighbours, and therefore will experience a different internal stress. Further, since on the whole all arrangements of neighbours are possible, the various members of the group taken together will exhibit a whole range of stresses from tension to compression, with a mean stress zero. Therefore the intergranular stresses measured by X-rays will vary at random about a mean zero stress, even though the selection of grains reflecting the X-rays has the same orientation. The regular type of internal stresses, which in contrast are characterized by a mean tensile or compressive stress, according to the experimental conditions, remains unexplained by the intergranular effects.

Indeed, it is difficult to see any manner in which the intergranular stresses could form a systematic system, because the stress-strain curve of a single metal crystal is notoriously structure-sensitive; the behaviour of the grain when part of a polycrystalline aggregate must be even more variable.

We have proved, however, that the intergranular stresses are irregular, even in grains of the same orientation, by experiments on the following lines. If the grain size of a metal specimen is sufficiently coarse, then a random distribution of neighbours for the similarly oriented reflecting grains is impossible. Then the intergranular stresses will not have a mean zero value at the point covered by the incident X-ray beam, but will vary irregularly from point to point in the specimen as different grains reflect. We have made a study of aluminium tensile test-pieces of various grain sizes and found this to be the case. The internal stresses were irregular in magnitude and independent of the direction of the previously applied stress, contrary to the suggestion made by Greenough. In such coarse-grained materials, where the inter granular stresses are not averaged out, it would be impossible to say whether the regular type of internal stress is present or not.

Further, it is interesting to consider the effect of the intergranular stresses on the X-ray diffraction ring itself. The diameter of the ring depends on the magnitude of the stresses in the reflecting grains; if the mean stress is tension, the diameter will change in one direction, and in the opposite direction if the mean stress is a compression. If, however, the stresses consist of a mixture of tensions and compressions about a mean zero stress, in the manner to be expected from the intergranular stresses in a fine-grained aggregate, then the diffraction ring will broaden radially, but will not change its mean diameter. Now this is the result found for copper. The diffraction ring from a copper tensile test-piece broadens most markedly after plastic deformation, but no appreciable change in the mean diameter occurs; if any change does occur it is masked by the diffusion of the ring and is too small for accurate measurement. In this metal, the irregular type of stress must predominate, although the metal is distinctly anisotropic.

We conclude that two types of internal stress may arise in a metal during plastic deformation: first, the irregular stresses which may be explained by the Heyn hypothesis of anisotropy and inhomogeneities of granular texture; and secondly, the regular type of internal stress which is of special interest because it must be associated in a fundamental manner with the response of the metallic lattice to external stress.

W. A. Wood
N. Dewsnap

Baillieu Laboratory,
University of Melbourne.

[1] Heyn, E., *J. Inst. Met.*, **12**, 3 (1914).

[2] Wood, W. A., and Smith, S. L., *Proc. Roy. Soc.*, A, **182**, 404 (1944). Wood, W. A., *ibid.* (in the press).

[3] Greenough, G. B., *Nature*, **160**, 258 (1947).

If a polycrystalline metal is being extended plastically, the tensile stress in any grain in the metal depends on the orientation of the grain and of its neighbours. When the applied stress is removed, the interactions between grains and their neighbours will result in a complex system of Heyn stresses, the residual stress in any grain being of the same order as the difference in the yield tension of the grain and the average yield tension of its neighbours. The important difference between this concept and that advanced by Wood and Dewsnap is that the latter consider the principal cause of the Heyn stresses to be the variation of the strength of the neighbours, whereas here it is considered that the yield tension of the grain itself is equally important.

Grains of a given orientation in the aggregate have different surroundings, so that the residual stresses in these grains will not be the same after a uniform plastic deformation. However, the mean residual stress, and hence the mean residual strain, in these grains will not be zero, but will depend on the difference between the yield tension of the grain with the given orientation and the average yield tension of the aggregate. It will also be closely related in direction to the original applied tension. The random variation from grain to grain, both in magnitude and direction, about this mean strain due to the effect of the varying surroundings of the individual grains is removed by taking a mean of the strains in a sufficiently large number of the orientated grains in the aggregate. Hence to determine the mean residual lattice strain in grains of a given orientation by observations on the maximum of a diffraction line, the experimental arrangements should be such that many grains contribute to the diffraction line.

The experimental conditions used in the work described previously were such as to ensure that many grains did contribute to each diffraction line. Not only was the grain-size of each specimen so small that enough grains were in the region irradiated by X-rays to give a uniform diffraction ring from the annealed material, but also the results quoted were a mean of the residual lattice strains determined, using at least three different specimens. There can be little doubt that the values of the residual lattice strains are mean values, and that the fortuitous variations in strain due to the varying surroundings of individual grains, although causing a broadening of the X-ray diffraction line, have been eliminated from the results quoted.

While it is considered that the experimental observation of residual lattice strains which represent both compressive and tensile stresses in a plastically extended aggregate is sufficient confirmation of the hypothesis, reference must be made to the success of attempts to interpret the hypothesis in numerical terms. A summary of the results has already been given[1], and it is hoped to publish the work in detail elsewhere. This hypothesis of Heyn stresses appears to give an adequate explanation of the observation of residual lattice strains, and it does not appear to be necessary to postulate any further type of internal stress.

It is interesting to note that the general hypothesis offers some explanation of the recent observation made by Wood and Rachinger[2] on the breadths of X-ray diffraction lines from iron filings and from a plastically extended aggregate. In the former, the stresses in the reflecting grains may have any magnitude and any direction relative to the X-ray beam; whereas in the latter, the stresses have a preferred value, although they show some variation about this value. Hence the variation of the strain in the direction of the reflecting normals in those grains contributing to a diffraction line will be greater in the case of the filings than in the case of the aggregate. One would therefore expect the breadths of the diffraction lines from filings to be greater than that obtained from a plastically extended specimen, if it can be assumed that the broadening is largely due to a variation of strain in the reflecting grains. This is, in fact, the result observed experimentally by Wood and Rachinger.

Electrical Breakdown Strength of Air at Ultra High-Frequencies

Difficulties in producing sufficient voltage to break down air gaps at ultra high-frequency have led recent investigators[1,2] to use pulsed magnetrons in order to obtain the high peak voltages that are required. The accuracy of the measurement of the electric stress which is obtained at breakdown in these circumstances must depend on a number of

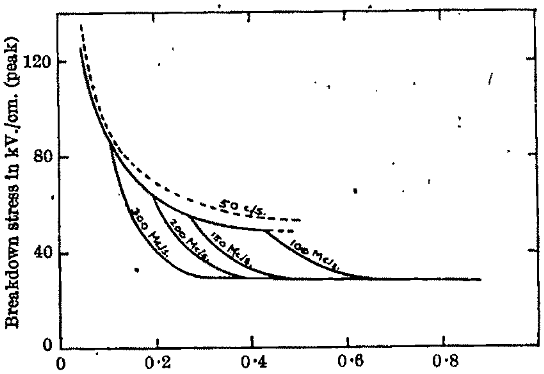

Fig. 1

factors, including pulse width, shape and repetition-rate.

The present series of experiments employs continuous waves throughout, and thereby enables some of the uncertain factors to be eliminated.

A method of measuring the radio-frequency voltage at the point of breakdown has been evolved which relies on the valuable property exhibited by 'Distrene', that its permittivity remains substantially constant over the frequency range 0–1,000 Mc./s. A form of dielectric voltmeter has been constructed which enables calibration to be carried out from a power frequency source.

Throughout the experiments the gap was irradiated by placing a small quantity of mesothorium near it. The effect has been to make the determination of the breakdown stress more precise. Without irradiation it is still possible to obtain the same value of the breakdown stress under given conditions, provided that the voltage has been applied for a long enough time to allow random irradiation to bring about the necessary initial ionization of the gas. A small spark discharge in the vicinity has also been found to give irradiation which leads to the same breakdown stress.

For frequencies in the region of 100–300 Mc./s. and higher, a discontinuity has been observed in the relationship between the breakdown stress and the gap width (Fig. 1). At a critical gap width (which varies with frequency) there is a sudden lowering of the breakdown stress to a constant value of about 28 kV./cm. at atmospheric pressure.

The variation of the breakdown stress at 200 Mc./s. with gas pressure has also been examined (see Fig. 2). It will be observed that the gap width at which the breakdown stress suddenly decreases is practically independent of the gas pressure. This is also true of the gap width at which the breakdown stress begins to become substantially constant.

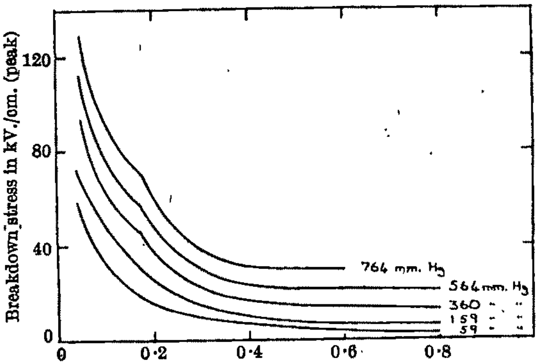

Fig. 2. f = 200 Mc./s.

These results suggest that, with an alternating field of a particular frequency, some charged particles are unable to cross the gap before the field is reversed. The sharpness of the breakaway would indicate that these particles are, in fact, electrons.

The flat portion would therefore correspond to the condition similar to an electrodeless discharge in which the electrons have space to move without coming into contact with an electrode throughout the time period for which the field remains in one direction.

The theoretical terminal energy U_T of an electron under the influence of an electric stress of E volts/cm. can be shown to be[3]:

$$U_T = \frac{0\cdot644\,\lambda E}{\sqrt{\eta}},$$

where λ is the mean free path and η is the fraction of energy lost per impact. From this it would appear that if there is a minimum energy for the electron to initiate breakdown, the corresponding field strength would be inversely proportional to the mean free path (λ) and therefore proportional to the gas pressure. This is, in fact, true of the flat portions of the breakdown stress curve over which the electron can attain its maximum energy (Fig. 3).

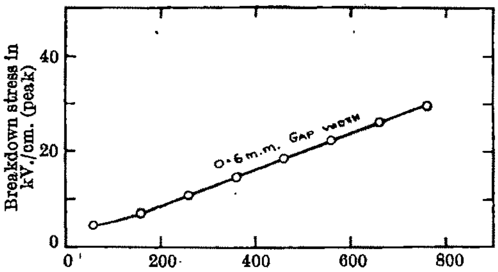

Fig. 3. f = 200 Mc./s.

Further investigations are in progress to examine these phenomena, with the view of establishing, if possible, the mechanism of breakdown for small gap widths.

Magnetic Susceptibility of Borax Glasses Containing Crystallites of Alkali Metal Salts, Gold and Platinum

In two previous communications[1], the results of X-ray diffraction experiments with salts of alkali metals, gold and platinum dispersed in boric oxide and borax glasses have been reported. It has been shown that crystallites of these substances exist in a finely divided condition in these glass media, the size of the particles in the case of the noble metals being somewhat greater than the colloidal particles of these in Zsigmondy's sols, which give only diffuse bands in their X-ray diffraction pictures, as opposed to the sharp lines which I have obtained.

Measurement of magnetic susceptibility of these systems has brought out certain interesting facts. The samples were prepared in the way detailed in previous communications, and their magnetic susceptibility determined in a magnetic torsion balance (Krishnan and Banerjee[2]). The susceptibility of the dissolved substance was calculated by the additivity formula :

$$100\chi = p\chi_1 + (100 - p)\chi_2,$$

where χ is the mass susceptibility of the sample, χ_1 that of the dissolved salt or metal, p its percentage, and χ_2 the mass susceptibility of the borax.

With the diamagnetic system $Na_2SO_4 - Na_2B_4O_7$, a surprisingly large value of χ for the dissolved salt is obtained, as will be seen from the following table :

Na_2SO_4–$Na_2B_4O_7$–glass system (Majumdar and Banerjee[3])

% Na_2SO_4	$\chi \times 10^6$ (calc.)	$\chi \times 10^6$ for pure Na_2SO_4
8·68	– 1·4389	
10·67	– 1·6428	
13·43	– 1·9394	– 0·337
15·62	– 2·0372	
17·36	– 2·2922	
17·71	– 2·3186	

A set of parallel measurements of the same salt in aqueous solution shows but slight increase in the value of χ for Na_2SO_4, as may be expected.

Na_2SO_4 aqueous solution (Majumdar and Majumdar, unpublished)

% Na_2SO_4	$\chi \times 10^6$
4·73	– 0·3577
7·12	– 0·3631
10·15	– 0·3700
14·30	– 0·3800

With the diamagnetic system $Au - Na_2B_4O_7$, the same increase is noticed; although the increase is not so large as in the previous case.

Au–$Na_2B_4O_7$–glass system (Majumdar and Basu Chaudhury, unpublished)

% Au	$\chi \times 10^6$ (calc.)	$\chi \times 10^6$ for pure gold
0·303	– 0·1512	
1·059	– 0·1528	
1·306	– 0·1538	– 0·1500
1·561	– 0·1552	
1·912	– 0·1574	
2·280	– 0·1604	
3·150	– 0·1682	

The system containing the paramagnetic platinum dissolved in borax glass shows, on the other hand, a decrease in the value of χ of the dissolved metal.

Pt–$Na_2B_4O_7$ glass system (Majumdar and Bhattacharyya, unpublished)

% Pt	$\chi \times 10^6$ (calc.)	% Pt	$\chi \times 10^6$ (calc.)	$\chi \times 10^6$ for pure platinum
0·319	0·9090	1·16	0·7413	
0·57	0·8948	1·41	0·7163	
0·69	0·8841	1·64	0·6359	1·10
1·021	0·8322	1·97	0·3134	

It may be mentioned that gold and platinum are not known to form any borates, and hence cationic exchange in the case of the first system is excluded ; so that the systems may be regarded as consisting entirely of the particles as such, held in suspension in glass.

These results, which in every case indicate an *increase* of diamagnetism of the dissolved particles, can be explained on my view of the effect of the dielectric medium on the lattices of the dissolved crystals[4]. The forces operating within a polar crystal are mainly two, namely, electrostatic forces due to the ions and the short-distance repulsive forces. If a medium possessing a higher dielectric constant is introduced, as is the case when the crystal dissolves in a glass, the Coulomb forces would be diminished and also the short-distance forces, so that a new equilibrium in the lattice will be set up with an increased spacing. This will explain qualitatively the observed increase of diamagnetism of the dissolved crystals. A similar explanation will also hold good for metallic lattices.

The change in magnetic susceptibility on the size of particles has been studied by different workers. But in all cases, such as graphite, colloidal bismuth, antimony, etc., the diamagnetic susceptibility has been found to be *less* than in bulk.

The increase in diamagnetism in the cases studied may be due in part (in the case of the metallic lattices) to the so-called Raman – Ehrenfest binding of the valency electrons. In such a case, the valency electrons have large orbits encircling a relatively large number of atoms ; but it is doubtful if the large increase observed could be explained by such an effect.

My thanks are due to the Indian Association for the Cultivation of Science, Calcutta, for permission to use the torsion balance, and to the Council of Scientific and Industrial Research for a research grant.

Bridge Networks Discriminating between Positive and Negative Sequences in Polyphase Supply

A NETWORK or filter constructed for use with single-phase supply will generally have a different transmission at different frequencies ; a network constructed for use with a three-phase supply has in general a transmission which depends not only upon the frequency of the supply but also upon its sequence.

Fig. 1 shows a bridge network for a three-phase alternating current supply which will transmit a frequency f equal to $1/\sqrt{3}\pi RC$ without change of voltage on condition that the supply has a phase sequence 1, 2, 3. If the phase sequence of the supply is reversed, the output voltage falls to zero. The diagram shows also the calculated transmission curve of the network.

It appears probable that any network which is not the same as its mirror image will show a transmission which changes when the sequence of the supply is reversed. G. B. Madella[1] has shown that the reversal of sequence in the phases of a multiphase supply is correctly thought of as being a reversal in sign of the frequency of the signal. A network may then be expected to have a transmission curve extending throughout the whole frequency range from plus to minus infinity, and the curve will not necessarily be similar in the regions of positive and negative frequency.

The network in Fig. 1 can generate three phases from a single-phase supply if the points 2, 3 and E are made common, and the input voltage applied to point 1, the neutral point and point 2 is in the ratio 1 : 0 : $-\frac{1}{2}$. The single-phase supply may then be regarded as the sum of two polyphase supplies of

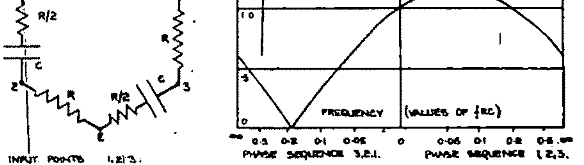

Fig. 1. BRIDGE NETWORK FOR THREE-PHASE ALTERNATING CURRENT SUPPLY, AND ITS TRANSMISSION CURVE

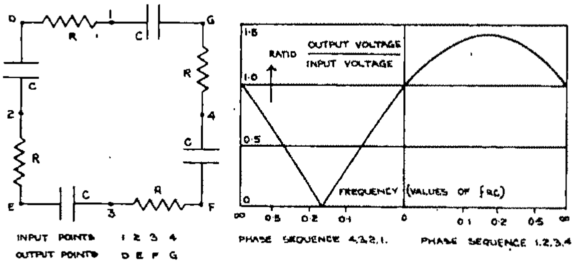

Fig. 2. BRIDGE NETWORK FOR FOUR-PHASE ALTERNATING CURRENT SUPPLY, AND ITS TRANSMISSION CURVE

opposite sequence, and the network transmits one and blocks the other. With this arrangement the impedances between points 2, *E* and 3 are, of course, omitted, and the arrangement appears as a simple phase-splitting network.

Fig. 2 shows a discriminating bridge for a four-phase supply of frequency *f* equal to $1/2\pi RC$, together with a calculated transmission curve. If this network is used to generate four-phase supply (or two-phase and neutral) from a single phase, then point 2, the neutral point and point 4 are made common, and voltage applied to points 1, neutral and 3 in the ratio 1 : 0 : −1. In this case the arrangement becomes a conventional phase-splitting network.

Madella has incorporated his concept of negative multiphase frequency in an improved form of heterodyne wave analyser[2]; he has also shown[3] that the concept gives a full explanation of the action of a modulating filter[4] which has been used in a modified form by D. G. Tucker[5] to give a highly selective transmission measuring equipment. Apart from the greater completeness which appears in the study of multiphase frequency as opposed to single phase frequency the concept seems likely to have considerable technical application and deserves to be more widely known.

Smoothing Periodograms from Time-Series with Continuous Spectra

IN his review[1] of M. G. Kendall's brochure[2] on oscillatory time-series, David G. Kendall made the pertinent observation that the smoothing of periodograms obtained from autoregressive or other time-series with continuous spectra is equivalent to considering the first few sample autocorrelations. I had arrived at a similar conclusion, though possibly by an alternative route, having noticed that the averaging of periodograms obtained from contiguous lengths of series is approximately equivalent to a truncation of the correlogram at a point represented by the length of the subseries. From preliminary computation already made on M. G. Kendall's artificial series to test out this smoothing device, it appears promising.

In terms of the periodogram intensity $I(\omega)$, standardized to have expectation equal to the variance σ^2 of the series if the latter were entirely random, and related to the correlogram by the identity

$$I(\omega) \equiv \sum_{s=-N+1}^{N-1} C_s \cos \omega s, \qquad (1)$$

where C_s is defined in terms of the observations X_r as

$$C_s = \frac{1}{N} \sum_{r=1}^{N-|s|} X_r X_{r+|s|}, \qquad (2)$$

the (continuous) spectrum of X_r, apart from a factor $1/(\pi\sigma^2)$, is the limit of $E(I)$ as N increases, where E denotes expectation[3]. For M. G. Kendall's series, with autocorrelations ρ_s satisfying $\rho_{s+2} + a\rho_{s+1} + b\rho_s = 0$, $(s \geqslant -1)$, it may be shown that this limit is

$$\frac{\sigma^2(1-b)\,(1-a^2+b^2+2b)}{(1+b)\,\{1+a^2+b^2-2b+2a(1+b)\cos\omega+4b\cos^2\omega\}}, \quad (0 < \omega \leqslant \pi). \qquad (3)$$

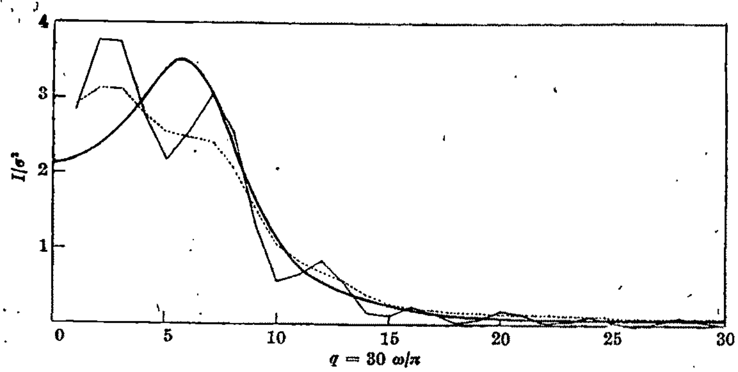
However, in accordance with general spectral theory and as remarked by the late P. J. Daniell, $I(\omega)$ unless smoothed never tends to this limit whatever N, random fluctuations being of the same order of magnitude as the expected value and only the 'resolving power' increasing.

The smoothing procedure first considered was to calculate

$$I_n(\omega) = \sum_{s=-n+1}^{n-1} C_s \cos \omega s, \qquad (4)$$

where n is a submultiple of N, chosen in practice to be a compromise between the averaging power required and the avoidance of bias in the expected value of $I_n(\omega)$. The standard deviation of fluctuations should be approximately reduced by the factor $\sqrt{(n/N)}$ and the bias should remain small if n is still large enough for ρ_n to be effectively zero. A variant of (4) which should be less subject to systematic error, though also rather less convenient since it implies fixing n in advance, is to replace C_s by

$$C_s' = C_s\left(1 - \frac{|s|}{n}\right) \Big/ \left(1 - \frac{|s|}{N}\right). \qquad (5)$$



SMOOTHED PERIODOGRAM (I_{16} JAGGED LINE, I'_{16} DASHED LINE) COMPARED WITH THEORETICAL SPECTRUM (SMOOTH CURVE).

In the diagram the expected intensity (divided by σ^2) is shown for Series 1 ($N = 480$), together with the values of $I_n(\omega)$ computed for $q = 30\omega/\pi = 1 \ldots 30$ and $n = 16$. There is a tendency to systematic oscillation in $I_n(\omega)$, but this is largely eliminated in $I_n'(\omega)$ (corresponding to C_s' in (5)), the values for which are also shown. Even $I_n(\omega)$, however, is a very great improvement over the unsmoothed periodogram, which includes a peak of 12 at $q = 3$ (see M. G. Kendall's Fig. 4.1, where it should be noted that the intensity contains an extra factor of approximately $2/N$ and is plotted against the trial period p, which is $N/8q$)

The arithmetical results also suggested the increase in the fluctuations about the mean as n was increased, but the computation (for most of which I am indebted to Mr. D. F. Ferguson) was carried out with the aid of the serial correlations recorded by M. G. Kendall, and hence was approximate and limited to n less than 48. It is hoped to test out and compare $I_n(\omega)$ and $I_n'(\omega)$ more precisely in due course. For Series 3 ($N = 240$) M. G. Kendall found the unsmoothed periodogram less confusing, owing to the closer approach of this series to an undamped harmonic, but the results for the modified periodogram still suggested an improvement even for n as low as 16.

Two further comments are: (i) this method of estimating the true spectrum could, of course, be improved if the correct form of the autoregressive scheme were assumed, its unknown constants estimated and the corresponding spectrum calculated, but a direct and more empirical estimation of the spectrum will often be required; (ii) the most rapid methods of obtaining spectra for series defined for continuous time avoid computation (for example, employ optical or electrical methods), and it may be possible to arrange for the smoothing to be carried out automatically without the above machinery of the truncated correlogram.

Race, Pigmentation and Colour Vision

BURT[1] has given evidence of a small correlation between darkness of skin pigmentation and colour-vision weaknesses. Vernon and Straker[2] have shown that red-green blindness is more common in the south and west of the British Isles, where the original dark-skinned inhabitants were pushed by the Nordic invaders. Geddes[3] has shown that red-green blindness is less common among the natives of Fiji than among peoples of Caucasian stock. Clements[4] has shown that red-green blindness is less common among American Indians and American Negroes than among American Whites.

Subjects whose colour vision was studied in Glasgow were classified as 'dark' or 'fair' on the basis of skin and hair pigmentation. There were 571 men and women who had colour vision with normal variations of sensitivity, and 138 colour blind and anomalous subjects (not all found by chance) who had major red-green defects which are sex-linked. There was no significant difference between the proportions of dark and fair among the normal and among the red-green defective subjects. The relative frequencies were:

	Normal subjects	Sex-linked red-green defectives
Dark	248	53
Fair	323	85

Protanopes, in whom the red end of the spectrum is greatly darkened, did not have dark skin pigmentation more frequently than deuteranopes. Sex-inked red-green defectives are on the average about ten times less sensitive to these colours than people with normal variations of colour vision. Any tendency for pigmentation to be coupled with major red-green defects in the population sampled in the south-west f Scotland would have been brought out by this xperiment.

Among the normal group as a whole no relationship was found between variations in sensitivity to any colour and skin or hair pigmentation. If, however, twenty members of dark-skinned races were taken separately, they were found to have significantly lower sensitivities to blue and yellow (but not to red and green) than the remainder. Of this group, nine who were Dravidians were significantly less sensitive to yellow and blue than Europeans, while six West Africans were significantly less sensitive to these colours than the Dravidians.

It would appear that pigmentation is not associated with loss of colour sensitivity in Britain, except where there is evidence of racial differences. Negroes and American Indians are less often red-green blind than Europeans; but Dravidians and Negroes are more often weak in yellow and blue.

Adsorption of Bacterial Polysaccharides to Erythrocytes

WE recently reported that saline extracts of smooth strains of *Hæmophilus influenzæ* (Type *b*) contain a substance adsorbable to erythrocytes[1]. Cells treated with such extracts are agglutinated by type-specific antisera. A sample of the type-specific polysaccharide, prepared by the method of Dingle and Fothergill[2], absorbed from immune sera their power of agglutinating erythrocytes so sensitized, but was not itself capable of sensitizing them. We concluded, therefore, that the fraction in saline extracts which was adsorbed to erythrocytes was a combination of the type-specific polysaccharide with some other substance.

Further work has shown that the assumption of another substance in combination is unnecessary. The sample of polysaccharide employed had apparently been degraded during preparation. Influenzal polysaccharide has since been prepared by extraction with 90 per cent phenol[3,4]. The phenol-insoluble, water-soluble fraction of the organisms contains the type-specific polysaccharide in an undegraded state in which condition it is adsorbed to the red blood corpuscle. If this undegraded polysaccharide is treated with dilute acid or alkali (0·01 N or less), it loses successively, first, the capability of being adsorbed to erythrocytes; secondly, the property of precipitation with antibody; and thirdly, the power of combination with antibody. The second and third of these changes have been shown by Morgan to occur during the hydrolysis of the polysaccharide of *B. Shiga*[5], and we have found that the undegraded Shiga polysaccharide is, like that of *H. influenzæ*, adsorbed to the surface of erythrocytes which then become agglutinable by Shiga antiser

We have, so far, prepared polysaccharides which adsorbed to erythrocytes from strains of *H. influ* *Meningococcus*, *Staphylococcus* and *Salmonella* *derby*, *typhi murium* and *pullorum*. Simil saccharides have been obtained from *Pn* and *B. proteus* by Dr. J. L. O'Connor *Streptococcus* by Mr. P. L. Bazeley, oratories. The relationship of these to recognized antigens and haptenes is being explored. This preliminary note is forwarded because we have found erythrocytes coated with bacterial polysaccharides to be useful reagents in various immunological procedures.

Our present technique is to add one volume of packed washed human or fowl erythrocytes to ten volumes of polysaccharide solution (0·1 per cent). The sensitized cells are then washed twice and re-suspended in normal saline in 5 per cent concentration. One volume of the suspension of sensitized erythrocytes is added to ten volumes of graded dilutions of antiserum, and the presence or absence of hæmagglutination is noted. The polysaccharide antibody content of sera may be rapidly estimated, by this procedure, and the polysaccharide content of solutions can be determined by their ability to inhibit such hæmagglutination. We have used these methods for estimation of the protective antibody in rabbit antisera for treatment of influenzal meningitis, and to determine the polysaccharide content of the cerebrospinal fluid of patients suffering from this disease.

An Adaptation Mechanism of the Organism to Damage: the Role of 'Resistine'

We have shown by experiments on rats and mice, using the Indian ink method devised by Jancsó[1], that the exposure of the organism to various damaging stimuli (injection of formaldehyde, adrenaline, agmatine, exposure to cold, X-ray irradiation, starving, surgical trauma, etc.) leads always to local and often general release of histamine. The site of histamine liberation looked as if it had been painted with Indian ink.

Though the shortening of the time of circulation of the intravenous injection of Indian ink solution (and according to Jancsó's observations that means histamine release, because the histamine is an effective activator of the whole reticulo-endothelial system) did not indicate *in vivo* histamine liberation because of the shock developed at the same time, the increased activity of the reticulo-endothelial system stimulated by released histamine could be detected in our perfusion experiments on surviving rat liver even in the stage of shock. 60–70 per cent more Indian ink was picked up during 40 min. from the perfusion solution by the surviving liver of the rat exposed to damage in comparison to the surviving liver of a normal rat.

It could be shown further that the histamine liberated by certain damage (what might be considered as a 'common pathway' in the adaptation mechanism) brings about as a basic factor all the changes haracteristic of the alarm reaction[2,3,4], causes shock nd plays also an essential part in setting in operation e defence mechanism of the organism, resulting lly in acquired increased resistance. In the stage of resistance, the Indian ink injected intravenously circulates in the blood significantly longer—about twice as long as in normal control animals. The prolongation of the circulating time is particularly pronounced when the resistant animal is investigated after having been exposed anew to damage. The results obtained in further experiments on resistant animals, when the surviving liver was perfused with Indian ink for 40 min., are in accordance with these findings. The amount of Indian ink absorbed during that time was 25 per cent less than that absorbed by the surviving liver of normal control animals. The absorption of Indian ink was especially diminished (more than 50 per cent decrease compared with the normal liver) when the animal has been again exposed to damage just prior to the perfusion experiment. Similar results were obtained with normal rats treated with antihistamine (Antistine s. Ciba or the preparation of Halpern 3277).

From these observations it seems clear that the increased resistance of the organism is caused by an excess formation of a substance possessing antihistamine activity. Since this substance, formed in the organism by its own cells, is responsible for the acquired increased resistance, it has been called by us 'resistine'. The antihistamine activity of resistine produced in great amount and stored in the organism will be apparent particularly when needed, that is, when the resistant organism has to face further damage.

Experiments concerning the chemical nature of resistine, the mechanism of its formation and its patho-physiological importance, other than the role of rendering the organism resistant, are already under way.

Two Examples of Sera Containing the Anti-*d* Agglutinin Predicted by Fisher and Race

Two sera which have been shown to contain the anti-*d* antibody have been referred to us by Dr. E. E. Dilworth of Shreveport, Louisiana, and Drs. J. W. Davenport and Bruce Everist of New Orleans, Louisiana. The first case, an iso-immunized mother of type *CDe*/*CDe*, produced a high titre of anti-c agglutinin which was greatly increased by the administration of small doses o *cde*/*cde* cells. Studies of the antibodies produced during this programme of stimulation showed the development of an anti-*d* antibody demonstrated by agglutination with *CDe*/*Cde* red cells. The second serum was also from a mother of genotype *CDe*/*CDe*. Fortunately the serum from this iso-immunized mother contained an anti-*d* agglutinin active with saline suspensions of red cells, while the anti-c antibody present at about equal titre did not react with saline erythrocyte suspensions but could be demonstrated with the Coombs (developing) test or with suspension of erythrocytes in albumin. Using the classical test-tube method with saline suspensions of test erythrocytes, this serum agglutinated cells of the following genotype: *CDe/cde*, *cde/cde* and *CDe/Cde*, but failed to agglutinate cells of genotype *CDe/CDe*, C^wDe/CDe, *cDE/cDE* and *CDe/cDE*. However, when the Coombs anti-human globulin method[1] was used to detect the antibodies, all erythrocytes containing the *c* antigen and/or the *d* antigen gave positive tests. The same results could be obtained by using albumin suspensions of erythrocytes by the method of Diamond and Denton[2]. Further agglutination studies ruled out any correlation with *A*, *B*, *M*, *N* or *P*. The possibility of the agglutinins present in these sera being identical to the anti-Kell[3], anti-Lutheran[4] and anti-Lewis[5] agglutinins was also ruled out by parallel tests with sera supplied by Mourant and Race.

To check further the identity of the agglutinin thought to be anti-*d*, the hæmolytic activity of the serum was studied by techniques previously described[6,7]. These studies showed an equivalent amount of hæmoglobin released at the end of 48 hours from cells of genotype *CDe/cDE* as compared with cells of genotype *CDe/Cde*. On the other hand, cells with antigens determined by a single gene dose of both *c* and *d* showed hæmolysis equal to the sum of that produced by the action against the cells containing one gene dose each of *c* and *d* respectively (*CDe/cDE* and *CDe/Cde*). These results not only seemed to confirm the identity of the anti-*d* and anti-*c* antibodies of the serum, but also revealed a unitary relationship between gene, antigen determined thereby and the amount of hæmolysis produced by the action of the corresponding antibody in the presence of complement.

Since Fisher has predicted a specificity of 64·43 for the anti-*d* agglutinin, it is of interest to note that the closely agreeing specificity of 65·16 per cent was obtained for the anti-*d* agglutinin of this serum when tested against 155 random blood samples of the white population. Furthermore, when the reactions were compared with those of anti-*D* serum, an antithetical relationship was found similar to *M* and *N*, as well as *c* and *C*.

In using the anti-*d* agglutinin, it was noted that certain genotypes could be resolved further. For example, type *CDe/Cde* could be differentiated from *CDe/CDe*. Likewise, *cDE/cDe*, *cDE/cdE*, *CDe/cDE*, *CDe/cdE* and *cDe/cde* could be demonstrated. Obviously family studies are still required for some genotype differentiations, for example, *Cde/cDe*. Efforts to produce usable quantities of the anti-*d* agglutinin by intentional stimulation are now under way.

Fibrinokinase and Fibrinolytic Enzymes

CONFUSION has arisen concerning the terminology of the fibrinolytic enzymes and pro-enzymes contained in blood plasma. In our papers on the fibrinolytic activator contained in tissue cells[1,2], we adhered to the nomenclature used by Loomis, George and Ryder[3], which is adequate from a biochemical point of view, and which has also been used recently by Guest, Ware and Seegers[4] and by Goldhaber, Cornman and Ormsbee[5].

Since the appearance of the paper of Ferguson[6] on the nomenclature of parenteral proteases, we have discussed the problem several times, especially with the group working under R. G. MacFarlane at Oxford[7], who use the nomenclature introduced by Christensen and MacLeod[8].

The major objection to the terminology of Loomis *et al.*[3] is that it does not avoid confusion with the term 'fibrinolysin', when used in its old sense as a substance originating from streptococci. This term is still being used by bacteriologists and serologists (immune antifibrinolysin). The term 'plasmin' for the active enzyme (Christensen[8]) suits all cases, as it is specific for the plasma enzyme and pro-enzyme.

The whole problem of terminology was discussed recently at the Conference on Blood Clotting and Allied Problems held in New York, February 16–17, 1948, under the auspices of the Josiah Macy, Jr., Foundation. No final agreement was reached, but it was recommended that authors should use both terms in the title and introduction of a paper in order to avoid confusion in abstracting and indexing.

The following observations may be added to those already published[1,2].

Fibrinokinase from pig's heart is completely devoid of action on chicken fibrinogen and fibrin. After incubating this pig fibrinokinase with ox pro-enzyme, a solution results with a powerful lytic action on chicken fibrin. This shows the specificity of the fibrinokinase and its properties as an activator for a proteolytic enzyme.

While the pro-enzyme present in ox serum will yield powerful solutions of enzyme after incubation with fibrinokinase from different tissues and animals, it is not activated by streptokinase. On the other hand, fractions of human serum containing pro-enzyme often yield very active solutions with streptokinase, but are activated to a far less extent by fibrinokinase even after repeated treatments. Such a solution, which cannot be increased further in potency by means of fibrinokinase, will upon addition of streptokinase develop a considerable amount of new activity. Thus there seems to be present in ox serum only one pro-enzyme, which is activated by means of fibrinokinase. In human plasma two pro-enzymes seem to be present, one of which is activated by fibrinokinase, and one by streptokinase. In order to distinguish between two such pro-enzymes and enzymes and in order to avoid confusion, we propose the terms: '*s*-profibrinolysin (*s*-plasminogen)' and '*f*-profibrinolysin (*f*-plasminogen)' for the two pro-enzymes which are activated respectively by streptokinase and fibrinokinase.

We have compared the fibrinokinase activity of normal tissues with that of malignant tissues. The results have so far been variable, showing that the activity often, but not always, is higher for the malignant tissue than for the corresponding normal tissue. An interesting case was encountered in which the primary tumour showed considerable activity, while a metastasis in the liver was just as inactive as normal liver tissue.

Finally, it may be mentioned that the thrombin B [9] used was found to contain a small amount of pro-enzyme which could be removed by extraction of the thrombin with 0·45 saturated ammonium sulphate and precipitation by adding solid ammonium sulphate (cf. Milstone[10]).

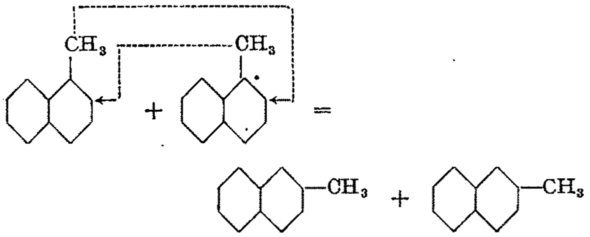
Mechanism of Substitution in the Naphthalene Nucleus

SUBSTITUTION in the naphthalene nucleus appears to occur initially at the α-position, while under more vigorous treatment an increasing proportion of β-substitution is observed; this tendency has been noted in alkylation by the Friedel-Crafts method by Roux[1] and by Tzukervanik and Terentieva[2]. We have found that by passing methyl alcohol and naphthalene vapours over catalysts of the alumina-silica type at 450°, β-methylnaphthalene and dimethylnaphthalenes are formed but not α-methylnaphthalene.

The suggestion that methylation first occurs at the α-position is supported by the results obtained when α-methylnaphthalene is passed over the catalyst at 450°. The initial material is completely transformed, yielding the β-methyl isomer as the main product, with smaller amounts of naphthalene and dimethylnaphthalenes.

As this transformation takes place in the gaseous phase, the methyl group doubtless migrates as a neutral radical. Moreover, there is evidence that the radical moves to a foreign nucleus[3]; for if the rearrangement were intramolecular, the formation of naphthalene and dimethylnaphthalenes would not be accounted for. It is possible that cleavage of the methylnaphthalene molecule to naphthalene and olefin takes place as a side reaction; but the formation of olefin cannot be an intermediate stage in the process: for in such a case, if the ethylene produced reacted with the naphthalene, ethyl, not methyl, derivatives would be formed. It is suggested, therefore, that an interchange of methyl groups between two molecules of α-methylnaphthalene occurs, the methyl group in the first molecule migrating to the β-position in the second molecule, while the methyl group in the second molecule moves to the β-position in the first molecule, thus:



The formation of naphthalene and dimethylnaphthalene would be accounted for as follows:

$$2C_{10}H_7CH_3 = C_{10}H_8 + C_{10}H_6(CH_3)_2.$$

Experimental details of this work will be published elsewhere.

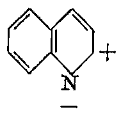
Nitration of Simple Heterocycles

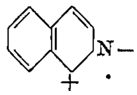
Two results of interest in the study of comparative heterocyclic chemistry have been reported recently. Nitration of 4-hydroxyquinoline is said to give c. 50 per cent of 3-nitro-4-hydroxyquinoline[1], whereas quinazoline provides not less than 56 per cent of the 6-nitro-derivative[2]. In identifying the product from 4-hydroxyquinoline, the authors[1] depended on (*a*) the proved difference of its 4-chloro-derivative from 5-nitro-4-chloroquinoline, its assumed difference from 8-nitro-[3] and 6-nitro-4-chloroquinoline[3], and (*b*) the assumed identity of the derived aminoquinoline, m.p. 94°, with 3-aminoquinoline[4]. We find that the chloro-derivative of the chief nitration product gives a strong mixed melting point depression with genuine 3-nitro-4-chloroquinoline[5]. Further, whereas the former may be crystallized from methanol, such treatment hydrolyses the latter. By analogy with 4-hydroxycinnoline[6] and 4-hydroxyquinazoline[7], we expected kynurin to give chiefly 6-nitro-4-hydroxyquinoline on nitration. In fact, the nitro-chloroquinoline, m.p. 144–145°, prepared as described by Mosher *et al.*[1], gave no melting point depression on admixture with genuine 6-nitro-4-chloroquinoline, m.p. 144–145° [3]. The derived 4-phenoxy-compounds, m.p. 117–118°, were also identical (found for genuin 6-nitro-4-phenoxyquinoline: C, 66·6; H, 4·0; N 11·4; $C_{15}H_{10}O_3N_2$ requires C, 67·6; H, 3·8; N, 10· per cent).

With regard to quinazoline, we have obtaine additional confirmation for the orientation of th main nitration product by converting it to 6-chloroquinazoline, m.p. 142–143°, identical with the compound prepared by Riedel's method[8] from 2-nitro-5-chlorobenzaldehyde (found: C, 58·4; H, 3·3 $C_8H_5N_2Cl$ requires C, 58·4; H, 3·1 per cent).

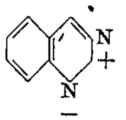
The theoretical interest of the last result is considerable. In the cases of quinoline and *iso*quinolin both simple resonance considerations of structures types I and II, and semi-quantitative molecul orbital treatment[9] are in agreement with experimen in predicting formation of 8-nitroquinoline and nitro*iso*quinoline. But they do not explain why i quinoline C_6, and in *iso*quinoline C_7, are by-passe



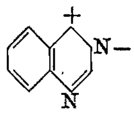
I



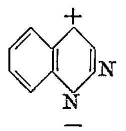
II



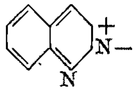
III



IV



V



VI

in favour of C_5 and C_8 respectively. Steric effects at these positions are not easy to visualize, and in the quinoline C_8 position at least, the adjacent bonds are similar to those around the acridine C_3 atom, a position which is attacked in nitration[8]. For quinazoline and cinnoline no quantitative calculations have been made, but the qualitative picture in the first case, based on structures of type III and IV, leads us to expect nitration at C_6 and C_8. This is partly borne out by experiment, and it remains to be seen whether the 8-isomer can be detected in the nitration product. For cinnoline, whereas structures V would lead to nitration at C_6 and C_8, the inclusion of types VI would produce deactivation at these positions also. However, since N_1 appears to be the basic centre[10], C_6 and C_8 are the probable points of attack.

It is clear that no adequate explanation of nitration orientation in heterocycles has yet been given, even if we leave aside the variations produced by different reagents[11].

Electrokinetic Potential and Surface Structure of Barium Sulphate

While there are many investigations on the influence of electrolytes on the electrokinetic or ζ-potential of solids, very few authors have considered the relation between the ζ-potential and the structure and composition of the solid itself. This is partly due to the fact that in many systems the potential-determining ions are foreign to the solid.

We are at present investigating the ζ-potential of sparingly soluble ionic solids such as barium sulphate against their saturated solution by the streaming potential method. In this case, the potential-determining ions originate from the solid. Precipitated barium sulphate is unsuitable for investigation, because the validity of the electrokinetic equations is limited to systems in which the diameter of the 'pores' of a plug is greater than the thickness of the electric double layer. We therefore prepared larger crystals (up to 2 mm.), which could be ground afterwards to any desired size, by recrystallizing barium sulphate from hot concentrated sulphuric acid and subsequent ignition. The following results are typical:

	ζ in mV.
Recrystallized barium sulphate, sample 1	+ 24·2
Recrystallized barium sulphate, sample 3	+ 25·0 ; 24·3
Recrystallized barium sulphate, sample 4	+ 26·6 ; 27·1
Natural barite, sample *B*, ignited	+ 5·4 ; 5·3
Natural barite, sample *C*, ignited	+ 8·4

In spite of the fact that during preparation of recrystallized barium sulphate there was always an excess of sulphate ion, the potential is *positive* and well reproducible within 1 mV. for each sample. The ignition temperature (500–1,000° C.) has no influence on the potential. Most electrolytes change the potential reversibly at room temperature; barium salts increase it, sulphates decrease it; but when, after treatment with the electrolyte solution, the potential is then measured against a saturated barium sulphate solution, the original value is always obtained. This value must therefore be regarded as a property of the sample. This behaviour is shown both by recrystallized barium sulphate and natural barite.

There is, however, a striking difference between the high potential of recrystallized barium sulphate and the much lower potential of natural barite. Spectroscopic analysis of our samples revealed that natural barite contains strontium and traces of calcium as impurities. However, these impurities cannot be responsible for the difference in potential. We incorporated such impurities into the recrystallized barium sulphate (during recrystallization); but, as a result, the potential was slightly increased, never decreased. Moreover, when natural barite is recrystallized from sulphuric acid, a high potential (27 mV.) is obtained.

These and similar observations, which will be discussed in more detail elsewhere, lead us to the conclusion that the difference in potential between recrystallized barium sulphate and natural barite is not due to a difference in composition. The most likely cause is a difference in structure (geometrical or otherwise) of the surface. Natural barite, even after crushing, has even crystal surfaces, whereas recrystallized barium sulphate has very irregular surfaces. This is shown by an investigation in an optical as well as in an electron microscope (for the latter we are indebted to Dr. A. L. G. Rees and Mr. A. J. Hodge of the Division of Industrial Chemistry of the Council for Scientific and Industrial Research). It is likely that the field of force is less well balanced in an irregular surface than in an even one.

Bikerman[1] suggested that the ζ-potential of a rough surface should be different from that of a smooth one for purely geometrical reasons. However, the distortion of the field of force in the surface as a factor influencing the electric potential at a surface is a somewhat unfamiliar concept in the field of electrokinetics. Nevertheless, besides our own observations, there are several findings of other investigators[2,3] which suggest that the ζ-potential of a crystalline solid is not solely determined by the composition of the system.

INHIBITION OF SH ENZYMES BY METHYL BROMIDE

By S. E. LEWIS

Pest Infestation Laboratory, Slough, Bucks

THE high toxicity of methyl bromide to man, and the insidious character of its action, particularly at low concentrations, were not realized when this compound was first introduced as a fumigant and as a fire-extinguishing agent, but are now well established and have been emphasized in a pamphlet recently issued by the Home Office[1]. Yet its mode of action has remained obscure. It has been frequently suggested that this action results from an accumulation of the products of hydrolysis[2,3], but the experimental evidence does not support this view[4], unless the hydrolysis takes place intracellularly[5]; a theory which would not explain the close parallelism between the symptoms of poisoning by methyl bromide and methyl chloride[6,7].

During an investigation carried out at this Laboratory on the nature of the bromide residue in wheat flour fumigated with methyl bromide, it became apparent that the protein fraction of the flour was mainly responsible for the sorption and decomposition of the methyl bromide[8,9]. Other workers have shown that when aqueous suspensions of wool, silk fibroin, collagen and gelatin are treated with liquid methyl bromide, methylation of carboxyl groups and peptide linkages occurs[10,11]. Similarly, the SH groups in bisulphited wool are readily methylated by such treatment, and S-methyl-cysteine has been isolated from the hydrolysate[12].

In order to determine whether these reactions occur when methyl bromide is present in low concentrations, buffered solutions of cysteine and reduced glutathione were exposed to methyl bromide vapour for periods up to four hours. Oxidation was eliminated so far as possible by exposing the solutions in an atmosphere of nitrogen, or by the addition of cyanide. The number of SH groups remaining after treatment was determined by the reduction of ferricyanide[13], and the ionizable bromide, resulting from the decomposition of methyl bromide, by the method of Kolthoff and Yutzy[14]. The results in Table 1 show that there is a progressive decrease in the number of SH groups and a corresponding increase in the non-volatile bromide in the solutions. Similar tests with oxidized glutathione showed no such increase in the bromide content of the solutions. This suggests therefore that, under the conditions described above, methyl bromide reacts preferentially with the SH group.

The most probable reaction is :

$$R\text{—SH} + \text{CH}_3\text{Br} \rightarrow R\text{—S—CH}_3 + \text{HBr} ;$$

and on this assumption the bromide content of the solutions, to be expected as a result of this reaction, has been calculated from the decrease in the number of SH groups (Table 1). The fact that more SH groups have reacted than can be accounted for by the bromide determined is probably due to some oxidation during the exposure or subsequent manipulation. Similarly, when solutions of reduced keratin, prepared by the method of Goddard and Michaelis[15], were exposed at pH 7·5 to methyl bromide at a concentration of 400 mgm. per litre, there was a progressive reduction of the strong nitroprusside reaction given by this protein. After two hours exposure, the reaction was almost completely abolished. It appears therefore that, although methyl bromide can react with a number of groups in protein molecules, under the conditions of these tests the reaction with SH groups is particularly rapid.

TABLE 1

	Time of treatment (min.)	Concentration of methyl bromide vapour (mgm./litre)	Mgm. of SH compound reacted	Non-volatile bromide (mgm. Br′)	
				Determined	Calculated
Cysteine hydrochloride 25° C. pH 7·0	60 90 240	400 380 360	2·1 2·75 4·0	0·93 1·26 1·85	1·06 1·40 2·03
Cysteine hydrochloride 37·5° C. pH 7·4	30 120 240	114 106 98	1·7 3·75 5·0	0·67 1·45 2·00	0·86 1·80 2·55
Glutathione 37·5° C. pH 7·4	20 40 80	200 200 200	0·6 1·0 1·45	0·135 0·202 0·380	0·151 0·270 0·380

The toxic action of a number of substances has been attributed to their ability to inactivate enzyme systems in the body by combination with SH groups in enzyme molecules. The work of Peters and his co-workers on the inhibition of brain pyruvate oxidase by arsenic compounds affords a particularly good example[16]. The toxicity of methyl bromide might similarly arise from its capacity for reacting with protein SH groups under physiological conditions of temperature and pH.

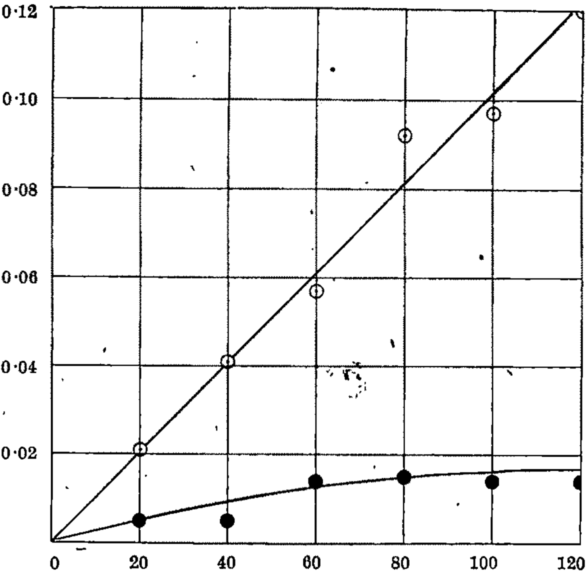
As a result of the above evidence, tests were carried out on some of those enzyme systems known to require the presence of SH groups for their activity. In each of the following tests the enzyme suspensions contained in all-glass flasks were exposed to known concentrations of methyl bromide at 37° C. At the end of each exposure, the free methyl bromide was removed by evacuation and 'air washing'. In each of the following systems, where free SH groups were present, exposure to methyl bromide vapour produced a progressive and irreversible inhibition.

Urease. A 1 per cent urease suspension, prepared from B.D.H. urease tablets, was used as a source of enzyme, and the activity after exposure to methyl bromide was measured by the method of Sumner[17].

Succinic dehydrogenase. An active extract of heart muscle was prepared and dissolved in phosphate buffer pH 7·4. After exposure to methyl bromide, the activity of the preparation was determined by measuring the oxygen uptake in the presence of 0·05 *M* sodium succinate. That the cytochrome oxidase portion of the system is not inhibited was shown by the fact that the addition of methylene blue did not increase the rate of oxygen uptake.

Papain. A 0·1 per cent aqueous extract of B.D.H. papain was treated with methyl bromide when in the reduced and also in the oxidized form. In each case the enzyme was activated with 2*M* sodium cyanide immediately before measurement of activity by the method of Anson[18]. The enzyme was rapidly inactivated by methyl bromide when exposed in the reduced form, but almost unaffected when oxidized. Simultaneous determinations of non-volatile bromide showed that the methyl bromide only reacted with the enzyme when the latter was in the reduced form (see graph).

Yeast (respiration). Fresh yeast suspended in buffered saline solution was exposed to methy



REACTION OF METHYL BROMIDE WITH PAPAIN, *p*H 7·4, TEMP. 37° C. CONCENTRATION OF METHYL BROMIDE IN AIR, 200 MGM./LITRE; —○—, REDUCED PAPAIN; —●—, OXIDIZED PAPAIN

bromide for periods up to 15 hours. After washing in isotonic saline, the oxygen uptake in the presence of glucose was measured. The reduction in oxygen uptake was accompanied by a rapid accumulation of acetaldehyde, which was readily detectable in the respiration flasks.

A few typical results obtained in the above tests are given in Table 2, together with the molar concentrations of methyl bromide dissolved in the solutions.

Enzyme systems containing essential SH groups show considerable variation in their sensitivity to inactivating agents, and it is not possible, therefore, to make direct comparisons between different systems. If the toxicity of methyl bromide to animal and plant ife is to be attributed to its ability to inactivate SH enzymes, some system forming an essential link in the chain of metabolic processes must be shown to be nhibited. Evidence of such inhibition in carbohydrate metabolism has been provided by Dixon[19], who has shown that hexokinase, which is present in the brain[20], is inhibited by methyl bromide. It is hoped that further work on this and other systems such as pyruvate oxidase will provide further information. The present findings do show, however, that methyl bromide is capable of combining with SH groups and producing a progressive and irreversible inhibition of those enzymes which have been tested. Such inhibition of an enzyme system in the brain would readily produce functional disturbances such as those associated with methyl bromide poisoning.

TABLE 2

Enzyme	Concentration of methyl bromide in air (mgm./litre)	Molar concentration of methyl bromide in solution	*p*H	Time of treatment (hr.)	Percentage inhibition

DETERMINATION OF RADIOACTIVE AND STABLE TRACER ISOTOPES

A MEETING of the Physical Methods Group of the Society of Public Analysts and other Analytical Chemists was held at the University of Birmingham on April 2. During the afternoon, about forty members visited the Physics Department at Edgbaston. Prof. P. B. Moon gave a short preliminary talk on the cyclotron and the synchrotron, and after a second short talk on target chemistry by Dr. F. E. Whitmore, parties were shown over the laboratories where the 60-inch cyclotron, now almost completed, was on view. The method of constructing the 800-ton magnet of the new synchrotron was explained in detail, and in smaller research laboratories several demonstrations had been arranged of experiments in radioactivity. After tea in the refectory at Mason's College, Edmund Street, the main business of the meeting was conducted under the chairmanship of Dr. J. G. A. Griffiths. Prof. M. Stacey welcomed the Physical Methods Group to Birmingham and stressed the importance of isotope measurements in a wide variety of fields.

A short symposium on "The Determination of Radioactive and Stable Tracer Isotopes" was opened by Dr. A. G. Maddock with a paper on problems in the measurement of β-activity, such as are met with in everyday practice. In spite of the development of ionization chambers connected to electroscopes or to electrometer valve circuits, and even of the more recent use of photomultiplier tube counters, the Geiger–Müller counter remains the most sensitive measuring device for β-rays. After mentioning briefly the working of such a counter, Dr. Maddock discussed the characteristics of the best counters and the means of avoiding spurious counts by using a quenching circuit such as that of Getting. Reduction of the background count of a Geiger–Müller tube can be very important where low activities are to be measured, and Dr. Maddock advocated careful selection of lead for 'castles' to shield counters and satisfactory design of both 'castle' and radioactive sample holder. That part of the background count—about half of it—which is due to cosmic radiation can be eliminated by the use of a second counter directly above the first and connected to it in an anticoincidence circuit.

If samples for counting are neither infinitely thin nor infinitely thick, a correction must be applied for self-absorption of β-rays in the sample. In a series of experiments when the same radioisotope is always used, it is worth constructing an empirical correction curve. Where several different isotopes are in use, however, corrections for self-absorption can be made with reasonable accuracy through the use of a nomogram connecting thickness of sample with half-absorption thickness of the isotope involved.

Dr. F. E. Whitmore followed, with a paper in which he considered the accurate estimation of radioisotopes the decay schemes of which are more complicated than those of a simple β-active isotope. Zinc 65, for example, has an exceptionally complicated decay scheme involving positrons with their accompanying annihilation γ-radiation and, in addition, γ-rays and X-rays arising from *K*-capture. All these types of radiation will affect a Geiger counter, but with differing efficiencies. Dr. Whitmore described an arrangement of two counters such that effectively one is sensitive only to γ-rays and the other only to β-rays, counts being measurable from each separately and the two in coincidence. In the case of an isotope decaying with β- and γ-rays simultaneously, the absolute number of disintegrations per second occurring in the sample can be found in terms of these counts only, independently of the β- and γ-efficiencies of the counters.

A further possible use of coincidence counting was suggested by Dr. Whitmore, in that two counters in coincidence are directional for γ-rays and might be used for the location of γ-active material in a living body, in place of the present arrangement whereby a single counter is used at the end of a long hole in a lead block.

The subject of measurement of the relative abundances of inactive isotopes was introduced by Dr. E. R. S. Winter, who first described briefly the development of the mass spectrometer and then, in greater detail, the construction of a modern mass spectrometer of the Nier 60° type. The instrument was considered in its three main parts of ion source, magnetic analyser and collector cup. By means of a block diagram, the equipment ancillary to the mass spectrometer tube was clearly demonstrated, and Dr. Winter explained the importance of slit widths and alignment in determining resolving power and the shape of mass peaks. There must be adequate separation between peaks over the mass range in which the instrument is being used, and if the tops of the peaks are flat, accurate measurement of mass abundance is made much easier. Dr. Winter pointed out the virtues of the mass spectrometer, this being a remarkably flexible and accurate instrument and much the best means of measuring isotopic abundances.

The feasibility of methods of stable isotope analysis using apparatus other than the mass spectrometer was the subject of a paper by Dr. E. R. Roberts. The high cost and complexity of mass spectrometers make it worth while to examine methods less elegant and more tedious which may yet be used in tracer experiments with stable material. Such methods include density measurements in both gas and liquid phases, and measurement of thermal conductivity in gases.

Quartz buoyancy balances similar to those used in the determination of the molecular weights of the rare gases can be used in the estimation of deuterium in hydrogen–deuterium mixtures. Accuracy is good in the case of hydrogen and deuterium; but improvements in technique may be necessary if heavier elements are to be used.

Several different liquid density methods have been used, again mostly for estimation of deuterium oxide in water. The most accurate is the determination of flotation temperature using a silica float calibrated with known water–heavy water mixtures. Determination of density by micro-pyknometer is also satisfactory, and in both these cases rigid chemical purification of the water is necessary. Another method of density determination is the falling-drop method, where drops of water fall through a very pure liquid in which they are non-miscible and which is of known density. Dr. Roberts also described the method of comparison of thermal conductivities, which has the advantage of requiring only very small quantities of sample.

Some examples of the use of tracer isotopes in the biological field were presented by Dr. W. J. Arrol, who did not attempt a survey of all the isotopes which have been used, but considered only iodine 131 of half-life 8 days. The uptake of iodine into the thyroids of human patients can be followed by placing a γ-counter over the gland and plotting activity of the gland against time after a single dose of radioiodide has been administered. The curve obtained can be used to diagnose departures from normal conditions both qualitatively and to some extent quantitatively, and more applications of tracer methods to diagnostic problems can be expected.

Two matters of importance to biochemists are the positive identification of the compound in which a tracer atom is combined, and the identification of the biological precursor of a compound. Dr. Arrol quoted in the first case the method used by Morton and Chaikoff in confirming the presence of radioiodine, from radiodide incubated with thyroid tissue, in thyroxine and diiodotyrosine extracted from the tissue. The radioactive residue extracted by an ordinary procedure is mixed with pure inactive compound and repeatedly crystallized. If the specific activity of the crystals remains constant, the radioactive residue is not chemically distinct from the pure compound with which it was mixed.

If a number of different 'labelled' compounds are administered to an animal, and one is found to be converted to a particular compound with greater efficiency than the others, it is quite likely to be the direct biological precursor. In a few cases, more evidence is obtainable by applying the criterion of Zilversmit, Entenman and Fishler, whereby variation of specific activity of a compound in a tissue with time and the variation with time of its immediate precursor are in a definite relationship with one another.

Dr. Arrol described the technique of making radioautographs and mentioned that recent improvements meant that accumulations of 8-day radioiodine 2·5 microns apart in a sample could be resolved in the radioautograph.

It was unfortunate that lack of time prevented any discussion on the papers, particularly as members were unable to bring up questions concerning the application of tracer methods to their own problems. The full text of the papers will be published in *The Analyst* in due course.

INTERNATIONAL RADIO CONFERENCES

TWO international radio conferences are being held in Stockholm during July. One of these will deal with the more fundamental aspects of radio science, while the other will be concerned with technical problems which form the basis of the practice of telecommunications. The two bodies, under the auspices of which these conferences are held, are in a sense complementary to one another in their functions; but there is naturally a good deal of common ground in their activities, and the choice of an arrangement of concurrent meetings this summer would appear to be a very happy one.

(1) *Union Radio Scientifique Internationale* (*U.R.S.I.*). The object of the International Scientific Radio Union is to promote scientific research in radio technique, particularly in those fields in which international co-operation is desirable or necessary. The Union is a constituent body of the International Council of Scientific Unions. Its headquarters and general secretariat are situated in Brussels, and the president is Sir Edward Appleton. The Union has held general assemblies in Washington, Brussels, Copenhagen, London, Venice (1938) and Paris (1946), at each of which a British delegation participated. The next general assembly will be held in Stockholm during July 12–22.

The work of the Union is divided between four Commissions, the titles and presidents of which are as follow: (I) Standards and Measurements, Dr. J. H. Dellinger (United States); (II) Propagation of Waves, Sir Edward Appleton (Great Britain); (III) Radio Noise, M. R. Bureau (France); (IV) Radio Physics, Prof. van der Pol (Netherlands). In addition o dealing with affairs at the general assemblies, these Commissions, together with any sub-commissions appointed from time to time, deal by correspondence, between the successive general assemblies, with work in the fields indicated by their titles.

The British National Committee for Scientific Radio is organised under the auspices of the Royal Society, as a constituent member body of Union Radio Scientifique. It comprises a few members ppointed by the Royal Society, and in addition epresentatives of the Department of Scientific and Industrial Research, the Radio Research Board, the National Physical Laboratory, General Post Office, British Broadcasting Corporation, Wireless Telegraphy Board, Meteorological Office, Institution of Electrical Engineers, Physical Society, Royal Society of Edinburgh and Royal Irish Academy.

It is customary for the various national committees to submit to each general assembly progress reports reviewing the advances made within their own countries in each of the fields of research designated by the above Commissions, and to submit any proposals for international action, which may include theoretical and experimental research, and, where desirable, standardization of equipment and nomenclature. As two examples of subjects in which this type of international action has been of great benefit to both the science and practice of telecommunications, those of frequency measurement and standardization and the study of the characteristics of the ionosphere may be quoted. In the former case, the connexions available through the Union have been instrumental in obtaining international agreement on the standards of frequency to a very high order of accuracy; while, in addition, the very advanced state of our knowledge of the ionosphere and of its influence on radio wave propagation owes much to the agreement obtained through the Union as to the essential quantities to be measured and the techniques used in doing so.

In addition to the preparation and submission of progress reports, the Union welcomes at its assemblies brief accounts of any outstanding and novel lines of recent research. In this case, the Union does not act as an alternative means of securing original publication, but rather as a forum for the discussion of appropriate items of work published in the normal manner elsewhere; and its own published account of such items is limited to about five hundred words.

The progress reports and the abstracts of original work referred to above are published by the Union in documents which contain also the proceedings and resolutions of each general assembly.

(2) *Comité Consultatif International des Radio-Communications* (*C.C.I.R.*). The International Advisory Committee for Radio is one of three technical committees which advise the International Telecommunications Union (I.T.U.) on all aspects of radiocommunication. The other two corresponding bodies are concerned with land-line telegraphy and telephony respectively.

The Committee is organised under the auspices of the Bureau of the International Telecommunications Union, with headquarters and secretariat at Berne. The Union itself is concerned with the framing of the general regulations which govern radiocommunication on an international basis and with the allocation of the frequencies required by different countries for various services in all parts of the world. For this purpose conferences of the Union were held at Cairo in 1938 and at Atlantic City in 1947; and the duty of the International Committee, which last met at Bucharest in 1937, is to study the technical problems associated with radiocommunication particularly in regard to its international aspects and to make appropriate recommendations to the Union for regulation.

It will thus be clear that the Committee is concerned with the technical problems which arise in the practice and operation of radiocommunication, and its members are the various national administrations controlling such communications. In the United Kingdom, the General Post Office is the appropriate administration for arranging for a delegation to participate in meetings of the International Advisory Committee; and for this purpose, that department organises a committee, with appropriate study groups, to prepare the documents to be submitted to the international conference. The committee contains representatives of all bodies, including Government departments and industrial organisations, concerned with the technical aspects of radio communication.

The next conference of the International Committee will be held in Stockholm during July 12–31, and among the subjects being studied in preparation for this are: (*a*) separation between frequencies assigned to radio stations; (*b*) international co-ordination of investigations on propagation; (*c*) methods of measurement of the field-strength of signals and of noise; (*d*) standard frequency and time-signal broadcasts; (*e*) monitoring of communication services; (*f*) distress signals.

INDIAN RESEARCH FUND ASSOCIATION

THE report of the Scientific Advisory Board of the Indian Research Fund Association (New Delhi) for the year ended December 31, 1946, gives some account of the researches carried out during the year on cholera, malaria, nutrition, leprosy, plague, pharmacology, maternity and child welfare, filariasis and other subjects, and includes the reports of the advisory committees as well as a list of papers published under the auspices of the Association, and the programme of researches and miscellaneous grants recommended for the financial year 1947–48. A cholera inquiry commenced at the Central Research Institute, Kasauli, is concerned with the substance and variability of the vibrios which may affect the efficiency of the vaccine used in cholera prophylaxis. The insecticide and mosquito repellent inquiry under the director of the Malaria Institute of India, Delhi, has covered the preparation of D.D.T. emulsion concentrates and aqueous suspensions, and field trials of D.D.T. solution, emulsions and suspensions and of 'Gammexane' solutions as residual sprays, as well as of turpentine, turpentine–toluene, and turpentine–rosin soap emulsions. A mammalian malaria inquiry covered studies of the experimental mosquito transmission of *Plasmodium cynomolgi* to *Macaca muletta* monkeys and the course of the infection and of the transmission of *P. cynomolgi* by blood and tissue sub-inoculation during the incubation period following sporozoite injection. An investigation of adult *Anopheles stephensi* was initiated at the School of Tropical Medicine, Calcutta, and another on the control of sand-flies, *Phlebotomus argentipes*, by spraying with D.D.T.

Nutrition researches under Dr. V. N. Patwardham at Coonoor have included studies of the vitamins of the B complex and the supplementary value of groundnut and coconut oil cakes in poor rice diets. Under Dr. B. N. Ghosh, at the University College of Science and Technology, Calcutta, studies of the biosynthesis of ascorbic acid by the rat have continued, as well as the inquiry into the chemical nature and nutritional availability of iron in foods; and the formation, function and variations of plasma proteins in health and disease have been investigated at the Grant Medical College, Bombay. The nutrition research unit at the University of Dacca has studied the metabolism of fat, the vitamin B complex, the relation between carbohydrate metabolism and nicotinic acid, the effect of soy-bean milk on growth; the similar unit at Seth G.S. Medical College, Bombay, in addition to fat metabolism, vitamin D and the enzymic liberation of nicotinic acid, has studied the nutritive value of pure-bred strains of cereals and pulses. In the laboratories of the Council of Scientific and Industrial Research at Delhi, a more exact determination has been made of the vitamin A activity of eighty-seven foodstuffs on the basis of individual carotenoids present. At the Women's Christian College, Madras, poor rice diets and food preparations in common use in South India have been investigated, and the evaluation of proteins in terms of hæmopoietic activity and the relation of dietary protein to blood and muscle hæmoglobin has been studied at the Biochemical Laboratory, University of Madras. The preparation of anti-rachitic substances and the nutritive value of soy-bean milk have also been studied at Poona and at Bangalore, respectively.

Leprosy research during the year at the School of Tropical Medicine, Calcutta, has included studies of promin, diasone, hydnocarpic derivatives of sulphonamides and aspergillin for the treatment of leprosy; work with stilbamidine has been continued and work with streptomycin has been concerned with its production from *Actinomyces griseus*. Some clinical, bacteriological and immunological work is also reported. Plague researches at the Haffkine Institute have included the effect of D.D.T. dust on the breeding of the Indian rat-fleas, *Xenopsylla cheopis* and *X. astia*; fumigation work with 'Cyanogas' and experiments with D.D.T. as pulicide are also described. Among the chemical researches reported may be mentioned that on Naga sore at the Pasteur Institute, Shillong, on hypoproteinæmia and other conditions associated with malnutrition and on erythroblastosis fœtalis and its association with the *Rh* factor at the School of Tropical Medicine, Calcutta, and the study of the anatomy of the foot with reference to infections of the foot at Stanley Hospital, Madras.

In pharmacology, the indigenous drugs inquiry has included studies of the effect of different methods of drying and of the age of the plants on the pyrethrum content of pyrethrum flower-heads, and on essential oil-bearing plants of the Kashmir valley. In the filariasis inquiry at the School of Tropical Medicine, Calcutta, the study of the action of the antimony compounds stibatin and anthiomaline was continued while the hæmatological unit studied the blood picture and protein content of healthy Indian vegetarians Chemotherapeutic investigations on kala-azar, the production of penicillin, anthelmintic trials of indigenous drugs against hookworm and ascaris infestation, the serological diagnosis of typhus fever by the Weil–Felix reaction and isolation of rickettsia strains, anaerobic wound infections, the manufacture of influenza virus A vaccine, the behaviour of membrane vaccine lymph in the field and the effect of cobra venom on the aerobic oxidation of *d*-glutami acid are among the miscellaneous researches reported.

The reports of the advisory committees cover much the same ground but include a number of important appendixes. Among these may be mentioned a summary of work done on cholera at the Haffkin Institute, a note of the recommendations for the fortification of staple foodstuffs from the Food Fortification Sub-Committee of the Nutrition Advisory Sub-Committee, and a note on the nutritiv value of 'Vanaspati' or hydrogenated vegetable oils.

scheme for the investigation of lathyrism, and notes on suggested lines of work on shock, the segregation and treatment of cases of tetanus with the view of clinical trials of V-187 in India, on the classification of clinical tetanus, and on a technique for removal of the brain and spinal cord in cases of lathyrism are also given. There are also reports on the distribution of typhus fever in the army in India, 1943–46, and of the sub-committee appointed to examine the possibility of maintaining sickness absenteeism records in Indian industries.

LATIN AMERICAN CULTURES

THE Institute of Social Anthropology, which has recently been formed within the Smithsonian nstitution, has started to issue an important series of monographs*. The five which have so far appeared deal with Latin America and have a very wide range. Their object is both scientific and practical, and the co-operation afforded by the national authorities both in Mexico and in Peru is a measure of the importance which they ascribe to the work. Leaving aside No. 1, on houses and house use of the Sierra Tarascans, which was published so long ago as 1944, he following brief comments are intended to give some indication of the nature of the series.

Nos. 2 and 3 are detailed studies of a small highland town in Mexico and of a coastal town of the same rder of magnitude on the coast of Peru. Although the people of Cherán are Tarascan Indians, with little white blood, speaking their native language and living principally by agriculture like their forefathers, the conclusion is reached that most traits of their culture are derived from Europe. This is not to say that it is a European culture, since the contact with indigenus Tarascan elements has caused it to develop into omething distinct from either; in fact, into what Mr. Gillin, in his monograph on Moche, would describe as a Creole culture.

Moche is by comparison a drab place, as the useful eries of photographs in each publication will show, but Mr. Gillin's analysis proves that its culture ontains a far higher proportion of indigenous lements. The town lies almost under the shadow of the two great pyramids of Moche, and, like them, ves its name to the ancient Mochica culture; but his had at least two successors before the Spanish onquest, so it must not be expected that much of has survived unmodified to the present time, as Mr. Gillin is careful to point out; and the remaining original elements are common to a number of e-Colombian cultures rather than specific to the Mochica. The difference between the two towns is ell illustrated by the accounts given of witchcraft each of them. The data for Cherán are far from omplete, but what there are have a completely uropean aspect, whereas those for Moche, which are ller, have a predominantly shamanistic comexion. In spite of the aboriginal survivals, however, he author shows that Moche has a Creole culture ather than an Indian one, but considers it likely hat it has changed considerably in this sense during he past generation.

No. 5 is a preliminary study, undertaken in order to choose a suitable place for more detailed work. It brings out the great variety in degree of change from Indian to white culture which is found in the Central Andes of Peru. One of its most illuminating features is a discussion of what constitutes an Indian, showing that racial criteria are so difficult to apply that a cultural definition is generally the only practicable one. In addition to introductory matter, which includes general accounts of the geography and the population, the paper contains interesting brief descriptions of most of the places visited. The town of Sicaya was chosen for further study, on the ground that it demonstrated best the process by which an Indian acquires a Mestizo culture and the Mestizo a white culture.

No. 4 is a voluminous and well-illustrated work, containing the geographical materials which an anthropologist needs to build on, particularly with regard to the use of land, and which he too often has to neglect owing to lack of specialized training. It will, presumably, be followed up by more purely anthropological studies.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, May 1

BRITISH PSYCHOLOGICAL SOCIETY (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Mr. David Katz: "Gestalt Laws of the Body Scheme".

Monday, May 3

FARMERS' CLUB (at the Royal Empire Society, Craven Street, Strand, London, W.C.2), at 2.30 p.m.—Lord Teviot: "The Lucas Report".

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE (at Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Prof. Frank H. Knight: "Economic Theory and the Good Society". (Further Lectures on May 10, 24, 31, June 7 and 14.)*

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. W. T. Winter: "The Development of the Jet Propulsion Engine".

CHEMICAL SOCIETY, LEEDS SECTION (in the Chemistry Department, The University, Leeds), at 6.30 p.m.—Prof. Linus C. Pauling, For. Mem.R.S.: "The Valence of Metals and the Structure of Intermetallic Compounds".

SOCIETY OF CHEMICAL INDUSTRY (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Annual General Meeting: Mr. B. A. Southgate: "The Treatment and Disposal of Waste Waters from Industry".

Monday, May 3—Friday, May 7

LIBRARY ASSOCIATION (in the Spa Grand Hall, Scarborough).—Annual Conference.

Tuesday, May 4

COUNCIL FOR THE PRESERVATION OF RURAL ENGLAND (at the Royal Institution of Chartered Surveyors, 12 Great George Street, London, S.W.1), at 2.30 p.m.—Annual General Meeting.

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (at the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Annual General Meeting.

ROYAL ANTHROPOLOGICAL INSTITUTE (joint meeting with the INTERNATIONAL AFRICAN INSTITUTE, at 21 Bedford Square, London, W.C.1), at 5 p.m.—Dr. Max Gluckman, Mr. J. H. Barnes and Mr. J. C. Mitchell: "The Village Headman in British Central Africa".

SOCIETY OF CHEMICAL INDUSTRY, CHEMICAL ENGINEERING GROUP (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. J. N. Pring: "Modern Propellants Employed in British Ordnance".

Wednesday, May 5

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. F. G. Mann, F.R.S.: "Recent Advances in Stereochemistry" (Pope Memorial Lecture).

PHYSICAL SOCIETY (at the Royal Institution, 21 Albemarle Street, London, W.1), at 4 p.m.—Annual General Meeting; at 5 p.m.—Prof. Yves Rocard: "Sur les conditions d'autooscillation des systèmes vibrants" (Third Holweck Discourse).

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY, SOCIAL PHILOSOPHY SECTION (at the Portico Library, Manchester), at 5.30 p.m.—Prof. J. A. Hawgood: "Education in Germany".*

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Scientific Papers.

Wednesday, May 5—Thursday, May 6

IRON AND STEEL INSTITUTE (at the Royal Institution of Chartered Surveyors, 12 Great George Street, London, S.W.1).—Annual General Meeting.

Wednesday, May 5

At 9.45 a.m.—Morning Session; at 2.30 p.m.—Afternoon Session; at 8.30 p.m.—Prof. Robert F. Mehl: "The Decomposition of Austenite by Nucleation and Growth Processes" (Third Hatfield Memorial Lecture).

Thursday, May 6

At 9.30 a.m.—Morning Session.

Thursday, May 6

ROYAL SOCIETY OF ARTS, INDIA, PAKISTAN AND BURMA SECTION (joint meeting with the EAST INDIA ASSOCIATION, at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Frederick E. James: "Tatas—a Story of 60 Years' Industrial Development in India".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

CHEMICAL SOCIETY, MANCHESTER SECTION (in the Chemistry Department, The University, Manchester), at 6.30 p.m.—Prof. Linus C. Pauling, For.Mem.R.S.: "The Chemical Bond".

CHEMICAL SOCIETY (at the Royal Institution, 21 Albemarle Street, London, W.1), at 7.30 p.m.—Sir John Lennard-Jones, F.R.S.: "The Molecular Orbital Theory of Valency".

Saturday, May 8

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, DIVISION FOR SOCIAL AND INTERNATIONAL RELATIONS OF SCIENCE (at the Assembly Hall, Leamington Spa), at 2 p.m.—Conference on "Human Factors in Industry".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURERS IN MATHEMATICS, a LECTURER IN PHYSICS, a LECTURER IN CHEMISTRY, a LECTURER IN BIOLOGY, SENIOR ASSISTANTS (2) to teach CIVIL AND MECHANICAL ENGINEERING subjects to Honours degree standard, LECTURERS IN ENGINEERING to teach in some selected branch of Civil or Mechanical Engineering up to Degree standard, LECTURERS IN ENGINEERING to teach classes of a Workshop and Production Engineering character up to Higher National Certificate, and a LECTURER IN ELECTRICAL ENGINEERING—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (May 8).

PRINCIPAL RESEARCH OFFICER to supervise the Electronics, Acoustics and Electrical Standards Sections of the Electro-Technical Division of the South African National Physical Laboratory, Pretoria—The South African Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2 (May 10).

LECTURER IN AGRICULTURE (HEAD OF THE DEPARTMENT)—The Director of Agriculture, School of Agriculture, Houghall, Durham (May 10).

SPECIALIST IN VISUAL AIDS at the Ministry of Education—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 2158 (May 13).

LECTURER (Grade III) IN MECHANICAL ENGINEERING—The Registrar, Queen Mary College, Mile End Road, London, E.1 (May 14).

LECTURER IN CHEMISTRY with special reference to Electrochemistry, and a RESEARCH ASSISTANT IN THE ZOOLOGY DEPARTMENT for work on Neurotoxic Insecticides with reference to problems of Locust Control—The Secretary of University Court, The University, Glasgow (May 15).

LECTURER (Grade II) IN STATISTICS, and an ASSISTANT LECTURER (Grade III) IN APPLIED MATHEMATICS—The Registrar, The University, Liverpool (May 15).

LECTURER IN THE MATHEMATICS DEPARTMENT—The Principal, Heriot-Watt College, Edinburgh (May 15).

LECTURER IN NATURAL PHILOSOPHY IN UNIVERSITY COLLEGE Dundee—The Secretary, The University, St. Andrews (May 15).

LECTURER IN CHEMISTRY—The Secretary, The University, Aberdeen (May 17).

LECTURER IN GEOGRAPHY—The Registrar, The University, Reading (May 24).

PRINCIPAL SCIENTIFIC OFFICER for Accidents Investigation in the Royal Aircraft Establishment, South Farnborough—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2153 (May 25).

PRINCIPAL SCIENTIFIC OFFICER, and a SENIOR SCIENTIFIC OFFICER, in the Ministry of Agriculture and Fisheries for employment at the Plant Pathology Laboratory, Harpenden—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2151 (May 26).

LECTURER IN APPLIED MATHEMATICS—The Secretary, The University, 38 North Bailey, Durham (May 29).

LECTURER IN THE TECHNICAL DEPARTMENT (for City and Guilds Telecommunications up to Grade 5)—The Technical Officer, University College, Southampton (June 12).

ASSISTANT LECTURERS (2. Grade III), mainly for research in Plankton and Algology, at the Port Erin Marine Biological Station—The Registrar, The University, Liverpool (July 15).

DESIGN ENGINEERS (Instruments), and STANDARDS ENGINEERS, IN THE DEPARTMENT OF ATOMIC ENERGY (Production)—The Staff Section, Ministry of Supply, Department of Atomic Energy, Risley, Warrington, Lancs.

LECTURER IN THE MATHEMATICS DEPARTMENT—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1.

LECTURER IN STATISTICS, a LECTURER (Grade I) IN PHYSICS, and a LECTURER (Grade II) IN PHYSICS—The Registrar, The University, Reading.

LECTURER IN ANATOMY (to take charge of dental and massage classes), in the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2.

LECTURER IN CHARGE OF AGRICULTURAL CHEMISTRY DEPARTMENT—The Secretary and Bursar, Seale-Hayne Agricultural College, Newton Abbot, Devon.

SCIENTIFIC RESEARCH AND INDUSTRIAL DEVELOPMENT

IN opening a discussion, over which Sir John Anderson presided, at the centenary meeting in 1931 of the British Association, Sir Arthur Fleming urged the establishment of a national organisation to provide means of analysing the possibilities which new ideas afford of developing new lines of manufacture. Since that time, there has been frequent consideration of the means of bridging the gap between the birth of an idea and its industrial application. Reporting back to the Economic Advisory Council in 1932, the Committee of New Industrial Development rejected the proposal for a national organisation, on the ground that there was no evidence of an important gap in the existing arrangements for industrial research. Various reports during the last decade, however, have emphasized the difficulties and expensiveness of pilot-plant development, and it has been a main objective of a sub-committee of the Parliamentary and Scientific Committee since 1943 to secure some modification of taxation policy in this connexion, and to promote a national organisation for the purpose.

In a debate in the House of Commons on April 19, 1944, Mr. C. R. Attlee, then Lord President of the Council, said that the Coalition Government recognized the need for the establishment of some fund to meet the cost of developing new inventions and of providing facilities for testing new ideas for industry. The same idea was in the minds of many members of Parliament of all parties when they tabled an amendment to the Investment Control and Guarantee Bill in 1945, and in subsequent discussions with the Lord President of the Council and the Chancellor of the Exchequer. That amendment and those discussions, it should be noted, were subsequent to the important changes in taxation policy, introducing special relief on account of obsolescence as well as for depreciation, which Sir John Anderson announced in introducing the Budget in April 1944.

In a valuable Statement on Problems of Scientific and Industrial Research in 1944, Nuffield College suggested that a special development fund might be desirable from which grants could be made in suitable cases for the large-scale experimental work required for the commercial development of discoveries in applied science. The statement also visualized the establishment of an institution on the lines of the Research Corporation in the United States, to act for the universities and technical colleges collectively in the matter of patents arising out of discoveries of commercial value made in the course of academic research, and to license the use of such patents in return for royalties. In a report on Industry and Research, in October 1943, the Industrial Research Committee of the Federation of British Industries likewise recommended the careful investigation of the desirability of creating such machinery; but favoured the creation of an independent and not a Government organisation for the purpose.

Still more recently, in its Final Report on the Patents and Designs Acts last September, the Swan Committee, in considering the development and exploitation of inventions of value in the public interest, expressed the opinion that the right policy is to treat all patents in respect of State-owned or State-subsidized inventions as a public asset and to vest them in a single central body, suitably organised, and with a staff competent to estimate the potential value of the inventions concerned and able to decide upon and take such steps as are necessary to develop and make full use of them in British industry. In the past, the policy adopted by Government departments in dealing with patents has varied widely, both in regard to the exploitation and disposal of the patent rights and in regard to the remuneration of the inventor. On the latter point, the Swan Committee, while noting the complexity and difficulty of determining what, if any, reward should be given to the originator for inventions evolved in the State service or with the aid of public money, observes that only for inventions of exceptional brilliancy or utility, or for some other special reason, can any award be justified. Whether this task should be entrusted to a distinct or independent body, such as the Central Awards Committee, or to a panel of assessors forming an integral part of the holding and exploiting organisation, is a matter for decision when the scope and function of such an organisation are considered in detail.

This is the background against which the Development of Inventions Bill (London: H.M. Stationery Office, 1948. 4*d*. net), which received its first reading in the House of Lords on April 13, must be considered. The Bill provides for the establishment of a National Research Development Corporation, which would have as one function the acquisition, holding, disposition and granting of rights in connexion with inventions resulting from such public research and, where the public interest is involved, in connexion with inventions resulting from other sources. The second function of the Corporation would be that of securing, where the public interest so requires, the development or exploitation of inventions resulting from public research, and of any other invention that, in the view of the Corporation, appears not to be sufficiently developed or exploited. In pursuance of this function the Corporation would be empowered to carry on any activity which may be advantageous or convenient for the purpose, and, in particular, to carry on or facilitate the carrying on by other persons of any business. Where such activities, however, involve the carrying out of any project for manufacture, the construction of works or provision of services, the provision of financial assistance in development or exploitation of any invention, or the acquisition of any undertaking, entire or in part, the approval of the Board of Trade is required.

The Corporation would consist of a chairman and managing director appointed by the Board of Trade, and not less than four or more than ten other members also appointed by the Board from those possessing experience and capacity in matters relating to science, technology, industry, finance, administration or the acquisition and disposal of rights in inventions. The Board of Trade would be authorized to make advances to the Corporation up to a total of £5 millions during the five years from the establishment of the Corporation, and temporary borrowing powers up to a limit of £250,000 are also proposed for the Corporation. The normal procedure envisaged is the licensing of a particular process or invention to an industrial undertaking, the Corporation fixing the royalty to be paid. The Corporation would be expected as soon as possible to meet its expenditure out of income; but repayment of interest on advances made by the Board of Trade might be waived during the first five years.

It will be seen, therefore, that there is already a large measure of support from all political parties in Britain as well as from independent opinion for the two main purposes of the proposed National Research Development Corporation. It is recognized that some uniform method is required in dealing with the growing number of inventions made by persons or groups of persons carrying out research work in the Government service, or engaged in research which is in some way subsidized by the State. This obviously includes the problem of academic research to which the Nuffield College Statement referred; while in its second function of developing any neglected invention or scientific discovery likely to lead to the creation of a valuable new industry or industrial process, the new Corporation should give a much fairer prospect of success to the inventor who has no capital resources of his own and who, in Great Britain, has often been notoriously unsuccessful in obtaining commercial backing.

The assumption by the Government of such special risk-bearing functions on behalf of the public is appropriate at a time when not only is new development of such vital importance to Britain's recovery, but also when the Government is doing much to encourage the taking of risks by the private individual. It is this positive aspect of the Corporation's work that requires emphasis. It was never contemplated in the protracted discussions over the last fifteen years, out of which the project has been born, that the Corporation should limit its activities to the discouragement or redress of restrictive practices. On the contrary, the proposed new body is to cover every range of industry in which for any reason a scientific invention had been neglected.

The National Research Development Corporation, being clearly the body envisaged by the Swan Committee, may possibly be expected to deal, *inter alia*, with the elimination of restrictive practices. This Committee, in its second interim report, recorded the opinion that the deliberate suppression of invention had been much exaggerated, and it could find no satisfactory evidence of particular examples of such practice. Nevertheless, even if this is only a minor activity of the Corporation, the relation of the Corporation to the Monopoly Commission which would be set up by another Bill already before the House of Commons should be made clear.

Recognizing that the Corporation is not intended to be unfairly competitive with British industry, but rather to assist industry to hold a leading place in industrial development, it is still true that the exact mechanism by which the Corporation is to achieve its purpose will require careful scrutiny. The idea of an independent organisation, supported by public funds, as suggested by the Federation of British Industries, has certain advantages which deserve careful consideration, especially where the powers of erecting and running pilot plants at the public expense are concerned. Without questioning the genuineness of the intentions of the present Government, the possibility must be borne in mind that at some time or other the powers of a Government corporation might be abused.

It should not be necessary to emphasize the importance, in view of the large measure of agreement on the value of creating such a Corporation which already exists, of discussion on amendments or the introduction of safeguards proceeding on objective and not on party lines. If the Corporation is to succeed, it will have to work in close co-operation with such bodies as the Federation of British Industries, the new development councils, the Trade Union Congress, and the various research organisations of different types. Moreover, although there are *prima facie* reasons for the Corporation reporting to the Board of Trade and coming under the surveillance of that department, its position with regard to the research effort of Great Britain may involve close relations with departments under the Lord President of the Council, such as the Department of Scientific and Industrial Research, as well as with the Advisory Council on Scientific Policy.

Much will obviously depend on securing the right men, not only for posts of chairman and managing director, but also for the ordinary membership of the Corporation. Everything will rest on their judgment, ability and vision. In any event, the new proposal must clearly be considered first of all in relation to the general research organisation of Britain; in this connexion the factors concerned include aspects of taxation policy already noted, the adequacy of existing types of organisation for industrial research, and the potentialities of new types on the pattern of the Mellon Institute and the Armour Research Foundation, to which also the Swan Committee referred. It should be remembered that at the present time the research development programmes of many enterprising British firms are seriously hampered by delays in the grant of licences and by the lack of either man-power or materials. Such factors may well hinder the activities of the new Corporation, and it were well to consider whether there is not some risk that by competing with existing industry for the available supplies it may indirectly accentuate such difficulties.

The proposed National Research Development Corporation, if it is established, will be launched in difficult times, and unless directed with imagination as well as wisdom its influence will not necessarily be wholly good. In order to achieve its objectives it may well need considerably more than the five million pounds proposed for the first five years; indeed, it may be necessary to reconsider the whole of the financial aspect.

In recommending the establishment of a research corporation to handle the matter of patents arising out of discoveries of commercial value made in the course of academic research and to license the use of such patents in return for royalties, the Nuffield Foundation was apparently thinking less of the expensive pilot-plant stage of development than of the application of the resulting revenues in payments to the universities for the furtherance of fresh research. The proposal was made as a means of avoiding any temptation to the universities to regard scientific work as a possible source of profit, while at the same time preventing academic research being made a source of unmerited profit to others or running to waste where it holds the prospect of real benefit to the public. The Nuffield Foundation statement noted that in the twelve years ending in June 1941, the Research Corporation in the United States had spent well over a million dollars in support of scientific and industrial research; hence from this point of view alone the present proposal for a National Research Development Corporation merits careful examination.

Fundamentally, as we have already indicated, the proposal raises the question of the adequacy of the whole structure of the organisation for scientific and industrial research in Great Britain, and as such it is important that there should be ample time for close and objective scrutiny of all aspects of the situation. It is to be hoped that neither in Parliament nor elsewhere will there be any attempt either to curtail that study and discussion, or to force a decision on party lines when so much has already been done to prepare the way for an impartial verdict.

EARLY ENGLISH COUNTRY LIFE

Village Life in the Eighteenth Century

By G. E. Fussell. Pp. 84+11 plates. (Worcester: Littlebury and Co., Ltd., n.d.) 9*s*. 6*d*. net.

AFTER an active official life, Mr. G. E. Fussell set himself to continue and develop the historical studies which had long made him known to all interested in English country life, and in this little book he has brought together in compact but very readable form a connected account of the English village as it was in the eighteenth century. It was an important period for our agriculture; during the first half Jethro Tull, by the introduction of the seed drill and the horse hoe, and Lord Townshend, by developing the method of crop rotation, were laying the foundations for the change from the old to the new agriculture which was brought about in the latter part of the century by Coke of Norfolk, Bakewell of Dishley and others. The author begins by describing the lay-out of the village, the three classes of people—landlord, tenant and labourer—the mode of government, how the people lived and what work they had to do in the various seasons of the year, their social life, the village trade and commerce.

There is nothing fanciful in the matter, and nothing sentimental or nostalgic in its presentation, but a plain unvarnished account of how the village would appear to us if we could go back through the years and see it. Work was long and arduous, though the pace was slow; pleasures consisted in visiting, sitting round the fire and drinking, the local ale-house being also the local club; there were numerous outdoor sports, some so cruel that they were later suppressed, for example, cock-fighting, bull-baiting, etc. Festivals and holidays were no longer as numerous as in the pre-Puritan days; but a number still survived, and the tradition of a 'Merrie England' is not altogether unfounded. The villagers were on the whole well clad; the poorer ones ate but little meat and had to live on bread and cheese, the bread often being made of mixed rye and wheat. Those better off could have a weekly dish of salted pork or bacon, often eaten with a hard ball of barley meal instead of bread. Milk and small beer were available, and for those who could afford it, tea and ale. At the other end of the social scale large quantities of meat were eaten, and the 'roast beef of Old England' was a reality.

The inadequate dietary and lack of sanitation resulted in widespread scurvy, skin diseases, small-pox, etc., and epidemics spread with alarming rapidity. The winter was terribly dreary; the cottages were cold, damp and draughty, the food was monotonous: the salt meat became worse and worse as the months went by, and only the more fortunate had any attractive food. Spring was welcomed with great joy—how great is testified by all the early poets.

The old agriculture is sufficiently described and also the management of the livestock. The student might wish for more actual references instead of the phrase "a contemporary writer", and it would have been interesting if Mr. Fussell could have told us of some of the ways in which the ingenious village women used wild plants and other natural resources. But these are small details: the book is full of interest, and it has some well-chosen and unusual illustrations. We can commend it to all interested in English country life. E. JOHN RUSSELL

ELECTRONICS

Electronics and their Application in Industry and Research

Edited by Dr. Bernard Lovell. Pp. xvi+675. (London: Pilot Press, Ltd., 1947.) 42*s.* net.

> "If seven maids with seven mops
> Swept it for half a year,
> Do you suppose", the Walrus said,
> "That they could get it clear?"

THE editor of a book on electronics might well assess his task as almost impossible and be excused if, in desperation, he shed a bitter tear. The subject is not only enormous; it has grown extremely rapidly at a period of our history when there has been no time for the writing of text-books. It is even doubtful whether any one writer could do justice to the whole of the subject without taking so long a time that the beginning of the book would be out of date when the last page was written. Dr. Lovell has wisely spread the load over fourteen colleagues, each one a specialist in the section of electronics in which he writes. The result, in the absence of drastic editing, gives the impression the old lady had when she read the dictionary—"Somewhat disconnected, though very interesting"; but at least Dr. Lovell has produced a good book thereby in a short time. The information cannot in general be found in any other book or books, it has hitherto been available only in numerous scientific papers; indeed, two months before the book was published, I was in need of some information on electronics for the jubilee celebrations of the discovery of the electron and was obliged to read more than fifty papers to glean what I wanted. All of it can be found within the pages of this compendium.

The book is not primarily about electronic engineering and the application of electronic control aids to industry; for that the reader might be referred to Dr. H. A. Thomas's paper in the *Journal of the Institution of Electrical Engineers* (1947). It concerns an old science revitalized; 'how to use electrons' as distinct from 'how to use thermionic valves'. One beautiful illustration of this is the television camera, described by Dr. J. M. McGee. Electrons are ejected by photo-emission, are focused by electron optics, and produce others by secondary emission; an electron gun employing the latest ideas of electron trajectories is used, together with an electron multiplier to make the apparatus a little more complicated—but a superb example of the electronic art.

The fundamental physical processes of electron emission are nicely, if perhaps too briefly, dealt with by Dr. F. A. Vick. This is one of the chapters that will have to be supplemented by much additional reading for the serious student of electronics; but for many engineers and physicists the details given are sufficient to explain the modern concept of the potential barrier and the factors which influence the escape of electrons from a surface. One very small omission here might be confusing to readers of Millikan: Dr. Vick states that the photo-electric threshold of all metals is in the ultra-violet; but readers will recall Millikan's work on sodium and potassium surfaces sensitive to visible light. The practical details of Dr. Vick's subject are fairly fully reviewed by Dr. H. G. Lubszynski and Dr. A. Elliott. I suspect that much of the Admiralty work on infra-red sensitive photo-cells is described here for the first time in public print, and this feature has been a special aim of Dr. Lovell, namely, to describe significant developments of the past decade not so far dealt with elsewhere.

There are some other great chapters in the book: Dr. V. E. Cosslett's is a model essay on electron microscopy written in the simple language of the Prayer Book of Edward VI. Even to a specialist it is delightful and extremely well illustrated. Dr. McGee's article on television is good, though too much space is devoted to earlier developments already well written up in popular language elsewhere. The account of servo-mechanisms is very exhaustive, but is much more akin to electronic engineering than the previously mentioned essays; in fact, there are two or three other chapters which could have been transferred to electronic engineering. The magnetron is not given the attention it deserves; an essay twice as long would not have been too much for one of the biggest developments of the war years. The chapter on high-frequency heating contains no reference to what, I thought, was almost the starting-point of this subject: Burch and Davis's book "Induction Heating". Dr. R. J. Pumphrey's article on electronics in zoology is frankly disappointing: the language could have been much more carefully chosen for an audience of catholic interests.

Other chapters will find general favour; on radar, on the betatron, etc. Indeed, I read the book from cover to cover with keen interest and am certain scientific men of a variety of callings will do the same.

T. E. Allibone

PROGRESS IN THE OIL INDUSTRY DURING THE WAR-YEARS

Reviews of Petroleum Technology

Vol. 7 (covering 1941–45). Pp. viii+535. (London: Institute of Petroleum, 1947.) 21*s*.

THE last volume in this series (for 1940) appeared in 1941, since when the exigencies of war prevented publication as hitherto. The present volume covers the quinquennial period 1941–45—critical war years—and its contents thus reflect the trend of petroleum technology over a wide field during the most abnormal times the industry has ever passed through.

The format has not changed substantially. Reviews of subjects, each written by an acknowledged specialist in the particular field chosen, follow precedent. Petroleum geology covers origin, migration and accumulation, sedimentation, salt-domes and search for oil. Geophysics ranges from seismic methods to radioactivity. Drilling deals with recent progress, well hydrology, records and completion factors. Incidentally, an oil-well depth record of more than 16,600 ft. was established in Texas in 1945. Production engineering is concerned chiefly with reservoir engineering and control and well engineering generally. Oil transportation includes an account of war-time activities in the United States, and data on pumping stations, pipeline welding and corrosion. Refinery process developments are perhaps the most striking features of the whole technology; there is much that is new and of great future importance in this section, which discusses varied treatments, refinery conversion and integrations, aviation fuel, fuel suitable for jet propulsion, toluene and cumine production, synthetic rubber and lubricants. A chapter on modern analytical and testing methods is followed by more theoretical reviews of the chemistry and physics of petroleum. Natural gas and benzole production are dealt with conventionally, and followed by a full survey of advances made in alternative fields including developments in hydrogenation, the Fischer–Tropsch process, low- and medium-temperature carbonization and other substitute fuels. There is a section on specifications for service fuels with details of aviation, pool, transport spirits (including detector dye), diesel and fuel oils; this has particular interest in the light of recent proposals concerning commercial petrol in Great Britain. A separate chapter on diesel fuels and gas oils, biased to research and development both in British and foreign (including Russian and German) spheres, throws some light on efforts made to combat shortages which were known to be prevalent during the later stages of the War and, for that matter, still continue so to be.

There are short reviews on war-time specifications for lubricants, asphaltic bitumen and road materials; the chapter on special products is comprehensive, ranging from derived chemicals and special hydrocarbon products to synthetic resins and rubber. The volume is rounded off with a chapter on petroleum literature, concluding with a name and subject index.

The following items find no special place here: gasoline, light distillates and furnace fuel oils, measurement, plant instrumentation, crude oil, petroleum and other waxes, insulating and hydraulic oils, engines and automotive equipment, legislation and statistics for Great Britain; these will be included in the volume for 1946 now in active preparation.

This volume represents a prodigious amount of bibliographical research into international literature published during the war period and reflects the greatest credit on all concerned. As a current work of reference on the aspects of the technology with which it is concerned, it is invaluable. The only blemish is the quality of the paper employed; but that, we are sure, is not the choice of the Institute of Petroleum.

H. B. Milner

POTENTIAL THEORY OF AEROFOILS

Theoretical Aerodynamics

By Prof. L. M. Milne-Thomson. Pp. xix+363. (London: Macmillan and Co., Ltd., 1948.) 40*s*. net.

AERODYNAMICS is the science of the motion of gases and is of great intrinsic interest; but the present importance of the science lies largely in its applications, for it provides the rational basis for the design of aircraft. The subject is growing rapidly and is already so large that it cannot be adequately covered, even at an elementary level, in a single text-book. Some of the major branches are: theory of aerofoils and of control surfaces, the boundary layer, turbulent flow, flow at speeds near and above the speed of sound, flow at extremely low pressures, heat transfer, theory of aircraft performance, theory of the stability, control and flutter of aircraft, aerodynamics of propulsion including the internal aerodynamics of propelling machinery. However, the theory of the irrotational or 'potential' flow of fluids about aerofoils holds a central position in applied aerodynamics, and it is based on classical hydrodynamics. The book now under review is almost wholly concerned with the theory of aerofoils and with the hydrodynamic basis. The subjects of viscosity and turbulence are not seriously discussed.

The author says in his preface that the book is based on lectures to junior members of the Royal Corps of Naval Constructors, and it is stated on the dust cover that the general standard of the book is that of a first-year university course. This is certainly much too modest; but it is true to say that the book is so clearly and pleasantly written that it could be read with profit by a bright 'freshman' or even by an advanced schoolboy. The author has evidently taken great pains over the exposition and has succeeded in avoiding difficult mathematics. The notation and treatment are, in general, similar to those used in the author's "Theoretical Hydrodynamics". Special features of the book deserving mention are chapters on lifting surface theory, on wind tunnel corrections, on subsonic and supersonic flow, and, notably, a treatment of the design of aerofoils for given pressure distributions. There are about 320 exercises, some of which are extracted from recent research papers.

To the reviewer it appears that the three chapters dealing with simple flight problems, moments and stability are so slight that they might well have been omitted, thus permitting the rather high price of the book to be reduced. The nomenclature does not always agree with that now current. Thus, the point which the author calls the focus of an aerofoil is usually known as the aerodynamic centre, and it is not correct that the quarter-chord point is called the aerodynamic centre. Also, the author uses the term 'adiabatic' when the more precise 'isentropic' would be preferable, and the symbol *I* for internal energy in place of enthalpy. The argument on p. 79 for using the principal value of the integral for the downwash is not adequate, as the author must be aware.

In conclusion, this is the most comprehensive and up-to-date book extant on the theory of aerofoils in steady motion, and is a very welcome addition to the text-book literature of aerodynamics. The printing of the book is excellent. W. J. Duncan

PLANT GEOGRAPHY

The Geography of the Flowering Plants

By Prof. Ronald Good. Pp. 403+25 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1947.) 30*s*. net.

THIS book, as the author himself states, "is devoted to plant geography in the narrower sense", plant ecology being outside its scope. As a consequence, the treatment is essentially factual in character rather than causal, and static rather than dynamic. The difficulties of any attempt at such restriction are at once apparent, despite the inclusion of chapters on geological history and plant distribution and a section devoted to the factors of distribution. However, within these limits the author has collected together many of the facts concerning the distribution of taxonomic aggregates over the earth's surface which will be a welcome addition to the botanist's library, the more so that much of the literature of the subject is widely scattered. More than a third of the text is devoted to salient facts of the distribution of families, genera and species, where many of the striking features of extended range, discontinuity and endemism are assembled and illustrated with more than forty maps portraying various types of occurrence, from the extended tropical range of the Palmæ and the cosmopolitan genus *Drosera*, to the discontinuity of the Magnoliaceæ or that of *Saxifraga geum* and *Dabœcia polifolium*.

The limitations of the method of approach are nowhere better seen than in the chapter on the dispersal of plants, which is a brief summary of the familiar facts without critical consideration of the bearing of these upon the problems of distribution. The value of special mechanisms of dispersal is assessed adversely on the grounds that "it can be said quite categorically that there is no real evidence that species possessing such mechanisms are more widely distributed"—a statement that embodies the wholly gratuitous assumption that area is a measure of dispersal efficiency and a confusion of thought between the significance of space and time.

Most of the text is concerned with the extent of distribution; but the occurrence of species within the county of Dorset is the subject of a chapter that aims at treating the intensity of distribution, and here Prof. Good extends beyond his allotted scope. This excursion contains much that is of interest from the author's own observations, such as the extension in recent years of *Bartsia viscosa* and the frequency gradients of species within the area; yet not only in this section but also in that devoted to the history and distribution of the British flora, one is rather left with the feeling of too little or too much.

It is, indeed, as a factual presentation that this book will find its chief use, and it is no doubt the realization of this that accounts for the provision of an index of plant names and another of persons and places, but not one of subjects. E. J. Salisbury

OPTICS IN HOLLAND

Achievements in Optics

By A. Bouwers. (Monographs on the Progress of Research in Holland during the War.) Pp. viii+135. (New York and Amsterdam: Elsevier Publishing Co., Inc., 1946.) 6 fl.

THIS is the first of a series of monographs, under the general editorship of Drs. R. Houwink and J. A. A. Katelaar, to be published on the progress of research in Holland during the five years of German occupation. Most of the material was, for obvious reasons, kept secret during the War. Though prepared in secret, the text of "Achievements in Optics", which gives a survey of optical work in the Netherlands immediately prior to and during the War, was actually ready for printing before the liberation. Technical difficulties delayed its appearance until a year later. As a result, no consideration is given, or reference made, to similar work in Allied countries, and it is difficult to appreciate how much of the work described in the monograph predates similar work which has appeared in scientific periodicals during the last few years. For example, both in the U.S.S.R. (notably by Maksutov) and in Great Britain, optical systems consisting of spherical mirrors and meniscus lenses have been investigated and developed. It speaks highly for the Dutch, however, that they, in spite of their isolation from other scientific workers, should have, simultaneously, made advances in both geometrical and physical optics of such fundamental importance. The descriptions of their new optical systems and instruments given in the monograph are, therefore, worthy of the closest study.

The monograph is divided into four main sections, and in the first, on new optical systems, the Schmidt camera and its aberrations, and the advantages o spherical mirror systems, several devised by Bouwers himself, are described in detail. The excellent optical properties of these mirror systems have been applied to the design of new cameras, a new microscope and new telescopes. The telescopes have a reduced overall length as a result of the great admissible aperture ratio, almost complete absence of chromatic aberration even at the border of the field of view, and little or no 'false light'. The physical optics section consists of two papers, the first by B. R. A. Nijboer, a pupil of Prof. F. Zernike, dealing with the diffraction theory of aberrations, and the second, by Prof Zernike himself, on the subject of phase contras microscopy.

The illustrations and diagrams are very clear, and the monograph is excellently printed. The flimsy cardboard covers are rather a pity, because the monograph will be in great demand for reference and intensive study. S. Weintroub

An Introduction to Analytical Geometry

By A. Robson. Vol. 2. Pp. viii+215. (Cambridge: At the University Press, 1947.) 10*s.* 6*d.*

THIS is a continuation of an earlier volume published in 1940. The most original part of Vol. 2 is Chapter 19, on general geometry. This, with its references to G_5, G_6 and G_7, is at first sight difficult to understand, but becomes clear and very interesting if we refer back to Chapter 8 of Vol. 1. The leading idea, expanded from a suggestion of the late Prof. G. H. Hardy, is that what is usually called analytical geometry of two dimensions is not one subject, but several. The simplest kind, called G_2, corresponds closely to Euclidean geometry G_1. G_3 is similar to G_2, but regards a 'point' as merely a term for an ordered pair of real numbers x and y. In G_4 these numbers are no longer real, but complex. In G_5 we keep the pair real, and supplement them by a third real number z, introduced to make the equations homogeneous. Points at which $z = 0$ are called points of infinity. G_6 has triplets of *complex* numbers, thus combining the advantages of G_4 and G_5. In both G_5 and G_6 the points of infinity and the line on which they lie are exceptional. In G_7 all points and lines are on an equal footing. Theorems which are true in one kind of geometry may be untrue or even absurd in another. This discussion clears up the paradoxes which used to puzzle us concerning lines at right angles to themselves and separate points the distance apart of which is zero. However, the schoolboy, for whom the author professes to write, may not find this part of the book easy.

The other chapters of Vol. 2 deal respectively with homography, involution, ranges on a conic, systems of conics, reciprocation, the general cartesian conic, foci and confocals, normals and evolutes, and special homogeneous co-ordinates. The amount of space given to trilinear and areal co-ordinates is much less than in the older books, in which these were often applied, at great length, to metrical problems for which they were unsuited. There is a good stock of examples, of varying degrees of difficulty. At first sight there appears to be an ugly misprint on p. 14, but on reference to the beginning of Vol. 1 it will be discovered that "wo" is not a misprint, but an abbreviation for "with respect to".

Teachers should examine the book carefully, for the freshness of the outlook will throw new light on several parts of what used to be looked upon as a stereotyped subject. H. T. H. PIAGGIO

A Bibliographic Classification

Extended by Systematic Auxiliary Schedules for Composite Specification and Notation. By Henry Evelyn Bliss. Vol. 2: Classes H—K; the Human Sciences. Pp. vii+344. (New York: H. W. Wilson Company, 1947.) 7.50 dollars.

THIS volume sets forth the specifications and schedules in Bliss's classification for anthropology and the medical sciences, psychology (including psychiatry), education and sociology, including ethnology, folk-lore, ethnography and human geography. The expansions for the medical sciences have been compiled with the assistance of Mr. C. C. Barnard, and those for physiology, medicine and surgery have more recently been revised by Dr. R. B. Singer. The classification for psychology has been compiled in collaboration with Dr. C. M. Louttit, while the schedules for sociology, social ethnology and folk-lore have been revised by Miss Beverly Stamm. Although Bliss's classification is little known outside the ranks of librarians and bibliographers, the scholarly introduction to this volume will be read with appreciation by many who are interested in the more comprehensive human sciences. Its interest is not so much in the explanation of the principles of the classification itself as in the discussion of the various complications involved, including questions of terminology, where an admirable and forceful plea for greater precision is advanced. Particularly in what he has to say on sociology, Dr. Bliss makes a valuable contribution to greater precision in the use of terms and in the relation of concepts and ideas which should be welcomed by all serious students in this field, independent of whether or not they adopt his classification as a convenient working tool. R. B.

The Graduate School Research and Publications

Edited with a Foreword by Prof. Edgar W. Knight and Agatha Boyd Adams. (University of North Carolina: Sesquicentennial Publications.) Pp. viii+461. (Chapel Hill, N.C.: University of North Carolina Press; London: Oxford University Press, 1946.) 22*s.* net.

THIS further volume in the imposing series issued in celebration of the sesquicentenary of the University of North Carolina records the development of the graduate school and describes the resources for research which the University possesses in its library, research laboratories, its permanent institutes, its learned societies and clubs and its various learned journals and allied periodicals. The library resources have already been described more fully in an earlier volume in this series, but the present volume also includes an account of the activities of the University press. Apart from Prof. Pierson's discussion of the future of the graduate school and the relations between teaching and research, in which that twin function of a university is firmly upheld, these parts of the volume are chiefly of historical interest. The greater part of the volume, however, is occupied by a comprehensive list of the individual publications of the faculty, the administrative officers and other members of the University staff from the founding of the University, arranged alphabetically by name and classified according to the various administrative offices and faculties, departments or schools.

Industrial Research, 1947

Advisory Editor: Dr. Percy Dunsheath. Pp. 535. (London and New York: Todd Reference Books, Ltd., 1947.) 25*s.* net.

THE second edition of this book represents a considerable advance on the first. The extraneous and redundant material has been largely eliminated, and a readable and adequate survey of progress in industrial research in Britain during 1946–47 by Dr. B. J. A. Bard replaces the hotch-potch of essays included in the first edition. The statements from Government and public bodies and from private organisations are properly classified, as is the information on university laboratories and the research laboratories of private firms. The sections on officially appointed committees and reports and on books, periodicals and films have also been improved, and the latter list, limited to books published in 1946 or in preparation in 1947, is much more useful than the earlier list. The report from the Industrial Research Committee of the Federation of British Industries on industrial research in technical colleges is given in full, and there are brief summaries of some of the reports from the Working Parties of the Board of Trade in so far as they touch research.

Generally the book shows evidence of balance and of planning which were sadly lacking in the earlier edition. If the editor would direct a little more attention to the last section, "Who's Who in Industrial Research", and include in that a reasonable proportion of the men responsible for the management and the actual conduct of industrial research, instead of the overwhelming preponderance of academic, consultant or government entries which at present characterizes it, he would come well within sight of the goal of a reference book which everyone concerned with the conduct or direction of research would wish to have on his desk, both for ready reference and as a convenient guide to sources of authoritative information in regular demand.

R. BRIGHTMAN

Smoke

The Problem of Coal and the Atmosphere. By Arnold Marsh. Pp. 306+21 plates. (London: Faber and Faber, Ltd., 1947.) 21*s.* net.

THE author of this book is a red-hot zealot; his cause is certainly a good one. Briefly, his thesis amounts to this—the smoke nuisance *can* be abolished, and it *must* be abolished. The question before us at the moment, however, is this. How far will this volume help to spread the gospel? It is difficult to be sure. If something, however rational and desirable in itself, is said too much, too often, and a little too loudly, a boomerang action sets in, and the reader's sympathy, if not lost, is perceptibly reduced. Maybe Mr. Marsh will see the yellow light; it is to be hoped that he will. Everybody will agree with him that drastic action is needed to deal with the ill-effects of atmospheric pollution upon works of art; but the efforts of the Ministry of Works and the National Gallery in 1937 receive no mention, though given considerable publicity at the time. However, smoke and toil seem synonymous—unluckily—in men's minds: witness those telling lines (my italics) originally composed for the Potteries:

"Where the busy sounds of labour
Rise, the best of human *incense*,
To the Throne of the Creator".

F. I. G. RAWLINS

Radio Engineering

By Dr. E. K. Sandeman. Vol. 1. Pp. xxiv+775. (London: Chapman and Hall, Ltd., 1947.) 45*s.* net.

THOSE who have come into contact with the author would expect the fresh and 'breezy' treatment given to the practice of radio here presented. In attempting to bring the novice up to the standard of the expert (not defined), the author dashes through all the subtleties of the academic teacher, collects an immense amount of information from his colleagues in the British Broadcasting Corporation, fills in many gaps, contributes much original thought, bends charts and methods to his will, and leaves one rather breathless at the prospect of what one is supposed to know, in addition to a flair for designing and costing, in order to be a modern radio engineer. Even so, we are warned that all this is only an approach if one desires to attain to the higher flights of radar and television.

The method has a disadvantage in that the practical applications of radio theory are those which are designed to meet the problems of the B.B.C., weighted somewhat by the views of one who has done creative work in that organisation for many years. With these slight reservations, one concludes that this text (including Volume 2 to come), so clearly printed and illustrated, bears comparison very well with recent American texts, and from many points of view is superior, in its decimal lay-out, and as a reference book for many topics.

L. E. C. HUGHES

Las heladas y la necrosis fria de las plantas

Por Plutarco Naranjo V. Pp. 126+14 plates. (Quito: Imp. de la Universidad, 1947.) n.p.

ALTHOUGH some attention is given to the physical aspects of frost occurrence, this welcome survey is chiefly concerned with the nature of the biological damage caused to plants by the occasional radiation frosts that occur at altitudes of 2,000 m. or more in Ecuador. A review of contemporary weather data confirms experience elsewhere that radiation frosts occur on nights of little or no cloud when the air and the surface soil are dry.

Freezing of the cell sap was not observed, and damage to the tissues by expansion of the sap is dismissed as a possible effect of frost. The damage is attributed to an increase in the acidity of the cellular protoplasm, a change in *p*H of about one unit taking place when the respiratory quotient is decreased at low temperatures. When plants were damaged, it was because this shift was sufficient to bring the protoplasm to its iso-electric point, and coagulation set in. A number of photomicrographs and photographs illustrate the effect of frost on the cells and on the plants.

Suggested preventive measures include: (i) formation of dense clouds of smoke over crops; (ii) watering seed beds on occasions when frost is forecast; (iii) initiation of research on the breeding of frost-resistant varieties of plants.

H. L. P.

A Book of Spiders

By Dr. W. S. Bristowe. (King Penguin Books, K.35.) Pp. 34+24 plates. (Harmondsworth and New York: Penguin Books, Ltd., 1947.) 2*s.* net.

THIS very pleasant essay will reveal to many readers details of the spider's life with which they were previously unacquainted. After an introduction which deals with some medieval opinions about spiders, Dr. Bristowe describes many striking devices by which these animals feed and protect themselves, and some remarkable examples of their conjugal and parental habits. He writes chiefly of the spectacular and the quaint; but, avoiding mere 'wonder-mongering', succeeds in emphasizing the diversity of the ways in which spiders have chosen, or been driven, to live.

A point of some significance emerges from his discussion of the spider fauna of small islands. He tells us that in an islet with some half-dozen species nearly every one belongs to a different family: in other words, there is one representative of each type of specialist—"the maximum number of species with the minimum amount of competition". It would be interesting to know whether students of other groups have recorded a similar phenomenon.

Dr. Bristowe has been able to use as coloured plates a most attractive set of water-colour drawings made in 1867–70 by A. T. Hollick for a supplement planned by Pickard-Cambridge, to Blackwall's grea work on British spiders. In rescuing these from oblivion, the Penguin Books have performed notable service to arachnology.

T. H. S.

NATURE OF FORCES BETWEEN LARGE MOLECULES OF BIOLOGICAL INTEREST*

By Prof. LINUS PAULING
California Institute of Technology

As I look at a living organism, I see reminders of many questions that need to be answered. Not all these questions are obviously important, nor would their answers be useful—but we want them answered. Thomas Wright in 1601 said, "Nothing is so curious and thirsty after knowledge of dark and obscure matters as the nature of man"—of scientific men especially, he might have said.

What is skin, fingernail ? How do fingernails grow ? How do I feel things ? How are nerves built and how do they function ? How do I see things ? How can I smell things, and why does benzene have one smell and *iso*-octane another ? Why is sugar sweet and vinegar sour ? How does the hæmoglobin in my blood do its job of carrying oxygen from the lungs to the tissues ? How do the enzymes in my body break up the food that I eat, burn it to keep me warm and to permit me to do work, and build new tissues for me from the food fragments ? Why do I catch cold when exposed through contact with an ailing person, get pneumonia, and then recover after treatment with a specific antiserum or a sulpha drug ? How does penicillin carry out its wonderful function of fighting disease ? Why am I immune to measles, whooping cough, poliomyelitis, smallpox, whereas some other people are not ? And finally, why is it that my children, as they grow and develop, become human beings, and show characteristics similar to mine, and their mother's—how have these characters been transmitted to them ?

The basic answers to all these questions are not to be found in books. Even though Chaucer said

"For out of olde feldes, as men seith,
Cometh al this newe corn fro yeer to yere ;
And out of olde bokes, in good feith,
Cometh al this newe science that men lere",

he was before long corrected by Francis Bacon :

"Books must follow sciences, and not sciences books".

To understand all these great biological phenomena we need to understand atoms, and the molecules that they form by bonding together ; and we must not be satisfied with an understanding of simple molecules—nitrous oxide, NNO, that Davy used to produce hysteria ; benzène, C_6H_6, discovered by Faraday ; penicillin, containing forty atoms in its molecule. We must also learn about the structure of the giant molecules in living organisms, such as insulin, with ,000 atoms in its molecule, hæmoglobin, with about 0,000, the disease-producing viruses, a thousand imes larger still.

Just two thousand years ago the Roman poet Lucretius wrote

> "Wine flows easily because its particles are smooth and round and roll easily over one another, whereas he sluggish olive oil hangs back because it is composed of particles more hooked and entangled one with another".

This is essentially the modern point of view, expressed by Lucretius, of course, only as a surmise, whereas to us it is a fact, of which we have a detailed understanding. Lucretius went beyond us in interpreting the taste also of substances in terms of the shape of their molecules, writing

> "There is this, too, that the liquids of honey and milk give a pleasant sensation of the tongue, when rolled in the mouth ; but on the other hand the loathsome nature of wormwood and biting centaury set the mouth awry by their noisome taste ; so that you may easily know that those things which can touch the senses pleasantly are made of smooth and round bodies, but that on the other hand all things which seem to be bitter and harsh, these are held together with particles more hooked".

I shall now present a detailed discussion of the shapes of molecules, and the forces between molecules, in order to show the extent to which this surmise, too, of Lucretius is substantiated.

Even though hæmoglobin is spoken of as a large molecule, the molecule is very small in comparison with our usual scale. If I look at my hand or watch a few feet away, the atoms subtend the same angle that oranges would on the surface of the moon. The molecules might thus be described as an aggregate of oranges, held together by bonds which in actual molecules are electrons circulating between the atoms. On this scale of 250,000,000-fold linear magnification, the nitrous oxide molecule of Davy's laughing gas consists of three atoms in line, N–N–O, the distance between the two nitrogen atoms being about 1·12 in. and between the nitrogen and oxygen atoms 1·19 in. (in the molecules themselves 1·12 A. and 1·19 A., where 1 A. is 1/100,000,000 cm.). Faraday's benzene molecule consists of twelve atoms: six carbon atoms arranged at the corners of a regular hexagon, with the carbon-carbon distance 1·39 A., and six hydrogen atoms, in the same plane, at the corners of a larger hexagon, the distance of each hydrogen atom to the carbon atom to which it is attached being 1·06 A. The structure of penicillin, determined by Mrs. Hodgkin and her collaborators, is also known, as are the structures of many hundreds of simpler molecules.

As yet the detailed atomic structure of no protein molecule has been determined ; but the vigour of the attack that is being made and the increasing power of the marvellous methods of investigation used in structural study permit the confident hope that the next decade or two will bring the solution of this great problem.

Much information is already available, however, about the general sizes and shapes of large molecules of biological importance, and also about their function. The most striking general property of these molecules is the specificity of their activity. For example, hæmoglobin, the red protein in the red cells of the blood, has the specific property of combining with oxygen in the lungs, and then releasing this oxygen in the tissues, thus making it available for the oxidation of foods. There is no other substance known that is able to combine with oxygen and release so large a fraction of the combined oxygen reversibly with the small change in partial pressure of oxygen existing between the lungs and the tissues. Then there are the enzymes, such as those involved in the catalysis of the processes of degradation and oxidation of foodstuffs. These substances all show a high degree of specificity in their action : in general, a particular enzyme serves the purpose of speeding up a particular single chemical reaction in the body.

---

* Friday Evening Discourse at the Royal Institution, delivered on February 27.

Specificity is shown in a striking way by antibodies. These are substances produced in the living body in response to its invasion by foreign organic material, such as viruses or bacteria. They have the power of combining specifically with the material (the antigen) that led to their production, and of neutralizing or incapacitating the antigen. Thus an antitoxin is able to neutralize its homologous toxin; an antibody against a virus or bacterium is able to prevent the virus or bacterium from reproducing, and thus to aid in the control of disease. An unfortunate incidental effect of this protective mechanism of the body is the occasional production of protein sensitization, leading to asthma and hay fever. Sufferers from protein sensitization, such as those people who are sensitive to egg white (ovalbumin), can testify as to the specificity of the reaction and to its delicacy.

The specificity of serological reactions can be shown by simple serological tests carried out in the laboratory. Thus if a minute amount of ovalbumin is injected into a rabbit, it is found that after a week or two the serum of the rabbit's blood will produce a precipitate when mixed with a solution of ovalbumin, whereas the serum of an uninoculated rabbit will not produce such a precipitate. The precipitate contains ovalbumin from the ovalbumin solution that is added to the serum, and antibody molecules from the serum of the rabbit. These antibody molecules are protein molecules, with molecular weight about 160,000, corresponding to the presence in the molecule of about 20,000 atoms. These anti-ovalbumin molecules have the power of combining with molecules of ovalbumin, but in general not with molecules of other substances. Only if another substance is extremely closely similar in its structure to the ovalbumin with which the rabbit was originally injected can the antibody combine with it. Thus a precipitate, somewhat smaller in amount than with hen ovalbumin, is formed by antibodies produced by hen ovalbumin when mixed with a solution of duck ovalbumin; but no precipitate is formed when these antibodies are mixed with a solution of ovalbumin from the eggs of birds of other species.

Dr. Karl Landsteiner showed by his experiments that animals are able to manufacture antibodies specific to chemical groups that do not exist in Nature. The power of formation of antibodies able to combine only with an injected antigen is hence not a power that was developed in the course of evolution, in response to interaction with this antigen at some earlier age, and in a particular individual called into operation by the inoculating injection; but is instead a general power, which enables the animal to cope with a foreign material, even of completely foreign nature to the animal and its ancestors throughout its course of evolution.

I became interested in the problem of the structure of antibodies in 1936, as the result of conversations with Dr. Landsteiner. I found that the complex phenomena of immunology could be clarified and brought into order by a theory of the structure of antibodies based upon the idea of the folding of the basic polypeptide chain of the protein precursor of the antibody into the most stable of the configurations accessible to it. This theory of the structure and process of formation of antibodies involves the acceptance of the suggestion that antibody and antigen have molecular structures that are mutually complementary, originally made by Breinl and Haurowitz, Jerome Alexander, and Stuart Mudd. If the molecule of gamma globulin that might become an antibody is considered to consist of a chain that might fold up into any one of a large number of configurations, with essentially the same stability, then in the presence of a molecule of antigen that configuration would be selected which is stabilized by interaction with the antigen. The configuration that would be stabilized is the one in which there is the greatest force of attraction between the folded polypeptide chain and the molecule of antigen; and this greatest force of attraction would result from the assumption by the folding polypeptide chain of a configuration which permits the parts of the chain to approach as closely as possible to a portion of the surface of the antigen molecule, and which also brings positive charges in the chain in close proximity to negative charges in the antigen, and brings hydrogen-bond-forming groups in the chain into juxtaposition with their complementary hydrogen-bond-forming groups in the antigen. A very high degree of specificity can be obtained if the surface area over which the complementariness of structure is exercised is great enough to include a good number of interacting structural units.

Experiments carried out with antibodies and antigens have shown that the configuration of the antibody molecules is very closely complementary to that of the surface of the homologous antigen; the antibody reflects or reproduces, in a negative way, the shape of the surface of the immunizing antigen to within about 1 A., that is, to within about one-half or one-quarter of the diameter of an atom. The forces that lead to the production of the specific bonds between antibody and antigen are thus interatomic forces that operate between atoms essentially in contact with one another, and are not long-range specific forces of attraction operating through great distances (on the atomic scale) through space.

There is a highly specific phenomenon of the chemistry of simpler substances that is closely analogous in its nature and its cause to the highly specific phenomenon of serological interaction; namely, the phenomenon of crystallization. Chemists are accustomed to using the process of crystallization as a method of purification: a crystal growing in a complex mixture of molecules is able to select from the mixture just the molecules of one kind, rejecting all others. Thus pure crystals of sugar may deposit from a jam in which there are molecules of thousands of different substances. The specificity of crystallization is the result of the same striving toward complementariness and the operation of the same interatomic and intermolecular forces that are responsible for the specificity of antibodies. A molecular crystal has the structure that gives it the greatest stability, which would result from the maximum amount of attraction for each molecule in the crystal and the surrounding molecules. Each molecule in the crystal is then in a cavity that conforms in shape to the shape of the molecule itself. The molecule may be described as complementary in structure to the remainder of the crystal; and other molecules, with different shape and structure, would not fit into this cavity nearly so well, and in general would not be incorporated in the growing crystal. We may hence say that life has borrowed from inanimate processes the same basic mechanism used in producing those striking structures that are crystals, with their beautiful plane faces their unfailingly constant interfacial angles, and their wonderfully complex geometrical forms.

I believe that the same mechanism, dependent on a detailed complementariness in molecular structure, is responsible for all biological specificity. I think that enzymes are molecules that are complementary in structure to the activated complexes of the reactions that they catalyse, that is, to the molecular configuration that is intermediate between the reacting substances and the products of reaction for these catalysed processes. The attraction of the enzyme molecule for the activated complex would thus lead to a decrease in its energy, and hence to a decrease in the energy of activation of the reaction, and to an increase in the rate of the reaction. Although convincing evidence is not yet at hand, I believe that it will be found that the highly specific powers of self-duplication shown by genes and viruses are due to the same intermolecular forces, dependent upon atomic contact, and the same processes of replica formation through complementariness in structure as are operative in the formation of antibodies under the influence of an antigen. I believe that it is molecular size and shape, on the atomic scale, that are of primary importance in these phenomena, rather than the ordinary chemical properties of the substances, involving their power of entering into reactions in which ordinary chemical bonds are broken and formed.

Even though the general picture of some important biological processes is becoming clear, our present knowledge of the detailed structure of the complex substances of biological importance is vague. We may expect that as more precise information about the structure of these molecules is obtained in the future, a more penetrating understanding of biological reactions will develop, and that this understanding will lead to great progress in the fields of biology and medicine.

SYNOPTIC WEATHER MAPS FOR THE ANTARCTIC

THE publication in 1946 of volume 6 of the Scientific Reports, Series B, dealing with the meteorology of the Australasian Antarctic Expedition 1911–14, and, more recently, of vol. 7 of the same series (Sydney: Gov. Printer, 1947. 40*s*.), is understood to complete the scientific literature dealing with this Expedition. Sir Douglas Mawson, its leader, was fortunate enough to secure the services of the late Dr. Edward Kidson, formerly director of the New Zealand Meteorological Office, for the writing of these two reports. Unfortunately, Dr. Kidson died suddenly before his work was quite completed, and for this reason chapter 1 of vol. 6, which was to have been an introductory chapter of a general nature, is missing, together with a final section that was to have dealt with the meteorological records of sledging parties. Vol. 7 was, however, fortunately complete.

Volume 6 is entitled "Discussions of Observations at Adélie Land, Queen Mary Land and Macquarie Island". The base in Adélie Land was in Commonwealth Bay, in about lat. 67° S., long. 143° E. At this base two factors combined to make temperature rather high for a land station in these latitudes, and to make the variations comparatively moderate. These factors were the presence throughout the year of open sea for more than fifty miles to eastward and more than a hundred miles to westward, and the considerable downward slope of the interior to the coast, which last prevented any stagnation of cold surface air such as was observed often enough at McMurdo Sound and to an even greater degree at Amundsen's headquarters at Framheim, still farther to the east. Much has been written about the violence and frequency here of katabatic gales from a direction slightly east of south, which represent the gravitational flow of the cold air from the high interior of Antarctica, and gave a mean annual speed of 43 miles per hour, and a monthly average of about 55 miles per hour in May 1912 and July 1913. Dr. Kidson discusses these winds in Chapter 4 of this report.

The base in Queen Mary Land was on a floating tongue of ice with a level top, and was about 14 miles from the shore of the Antarctic continent, in about lat. 66° S., long. 95° E. In place of the open sea off the base at Commonwealth Bay, there was the extensive pack-ice belt; although there was a steep slope from the interior to the coast, the absence of open water prevented there being the very great thermal contrast across the coast inevitable at Commonwealth Bay, and the extreme violence of the wind was absent; while there was nothing to prevent the formation in quiet winter weather of a shallow layer of very cold air. As a result of this difference, the average diurnal variation of temperature at the Queen Mary Land base was nearly double that at Commonwealth Bay, and much lower extremes were recorded.

The weather at Macquarie Island, which is 22 miles long but only 3½ miles wide at the widest point, was dominated by the influence of the Southern Ocean. The latitude being about 55° S., the island lies well within the belt of stormy westerly winds that encircle the globe between about latitudes 40° S. and 60° S.; and since the station was on an isthmus only about 200 yards wide, and the island was treeless, it was much exposed to these winds. A large part of the space devoted to the observations is taken up with an analysis of these winds, which, at least partly as a result of the local topography, were much more often from north-west than from south-west. Directions from between south-south-east and north-north-east had a total frequency of only 8 per cent.

The seventh and last of the Scientific Reports, Series B, is entitled "Daily Weather Charts extending from Australia and New Zealand to the Antarctic Continent". These cover the period February 2, 1912, to January 31, 1913, and occupy most of the volume; but several subjects of great interest and importance are also discussed in the 31 pages of introductory and explanatory matter which precede them. Among them is that of the ring of anticyclones which encircle the southern hemisphere in about latitude 35° S. As Dr. Kidson points out, the regular procession of these from west to east has attracted attention ever since daily weather charts were first drawn for the Australian region. They are shown to be closely connected with the depressions and fronts of high southern latitudes, and have to be taken into account when daily charts are drawn to include the Antarctic continent. After giving a statistical analysis of the movements of these anticyclones between long. 120° E. and 170° E., and a discussion of the difficulties that arise in this connexion from the apparent temporary disappearance of a particular anticyclone, or from its division into two, or junction with another anticyclone, the view is put forward that the moving anticyclones originate as some periodic function either of the upper atmosphere or of the whole atmosphere, which is continually tending to produce them at intervals of about 45° of longitude.

Perhaps the most important conclusion reached by Sir George Simpson in the first report of this series, which appeared in 1919, is that relating to the travel of pressure changes in the Ross Sea region, deduced from synchronous observations made at Framheim, Cape Evans and Cape Adare. He concluded that it is only quite exceptionally that the barometric maxima and minima at these places are caused by travelling cyclones and anticyclones, and that as a rule they are due to "long and deep pressure waves radiating out from the Antarctic continent and extending over the Southern Ocean to some unknown distance from the Continent, traces of which can still be seen in the pressure curves for Kerguelen". He obtained evidence to show that the centre from which the waves radiated was not at the Pole but in about lat. 80° S., long. 120° W. With these conclusions Dr. Kidson, it appears, is not in agreement, largely as a result of the construction of the daily weather charts reproduced in this seventh report. He subjects the data used by Simpson to a fresh analysis and remarks, when discussing the times of occurrence of pressure changes at Cape Evans, Adélie Land and Queen Mary Land, that it seems quite impossible to reconcile these with the idea that the pressure maxima are caused by pressure waves as described by Simpson.

It may seem at first sight rather surprising that after such thorough analysis of the meteorological observations of this Expedition, there should be disagreement on such a fundamental point; but many of Dr. Kidson's daily weather charts show a feature that may partly account for this state of affairs, and that is the extent to which the fronts are bent towards a west–east orientation as they reach high latitudes, with an accompanying diminution in the temperature contrasts between the cold and warm air. This tends to make identification of fronts difficult; moreover, when the front is bent almost to an east–west orientation, the intervals of time separating its eastward passage across stations in different longitudes can be greatly affected by small differences between the latitudes of such stations. It is, however, a matter that can scarcely fail to be settled as the number of observing stations is increased.

WORLD FORESTRY AND FOREST PRODUCTS

A PRELIMINARY investigation of the greatest importance has been carried out by the Forestry Section of the Food and Agriculture Organisation in connexion with the examination of the world's resources in forests*, and a consideration of improved methods by which these resources should be utilized and improved. It is stated that this investigation could only be a preliminary one.

Almost one-third of the earth's surface, 4,000 million hectares, is classified as forest soil. These soils occupy twice as much area as all the land under cultivation, but their contribution to human welfare, while very great, could be increased many times if the 500 million hectares now denuded and useless could be restored, and if the 2,000 million hectares yet untouched could be opened and put under good management. Only one-third of the world's forest area has so far been brought into use, and less than 300 million hectares are under systematic forest management. The other thousand million hectares which constitute the overwhelming bulk of all forests in use are cut with little or no regard to their continued productivity. In other words, forest management is still fairly limited, since it extends at best to one-fourth of all forests in use, and to less than 10 per cent of the world's forest soils.

The preface of this report is written by Sir John Boyd Orr, director-general of the Food and Agriculture Organisation, and he commences by saying: "In dedicating itself to the goal of freedom from want, F.A.O. must devote a major effort to restoration of the world's forests, and to the effective use of their products". With the appointment of Marcel Leloup, formerly director-general of the Départment des Eaux et Forêts in France, as director of forestry and forest products in the Organisation, the first step in making international forestry an accomplished fact was taken. As this brochure displays, already a certain amount of world forest statistics had been gathered together but, as Boyd Orr says: "The goal before the Branch lies far beyond initiating statistics and collecting information. Forestry in F.A.O. will take an active part in helping Member Governments deal with their forest problems and in advising them on their forest policies."

One of the studies already made is the result of war's impact on forests, particularly in Europe. Here the direct effects were found to be far less damaging than had been expected. Land and aerial warfare inflicted serious local damage only in the areas of actual fighting. With the exception of the forests of Greece and Poland, which were badly devastated, European forests emerged from the War practically intact. On the other hand, over-cutting in the accessible forests throughout the world, enhanced during the War, has been very serious, and post-war requirements, especially perhaps building requirements in Western Europe, including Britain, are placing an added burden on the forests in which already excess fellings have been made.

Some of the causes of the present scarcity, such as insufficient man-power, disorganised transport and inadequate equipment, are only temporary factors which can be got over; but the basic ones are more serious, and include deforestation, inadequate forest management, failure to develop mature forests, incomplete utilization and insufficient technical personnel.

On the subject of deforestation, it is well known that in large portions of the world continuous mismanagement, fire and unrestricted grazing have led to complete destruction of the original forest cover. Vast denuded areas, deprived of the productive forest, have become wind-swept deserts, barren mountain slopes, and eroded valleys, where agriculture is almost impossible, and living standards have remained at starvation levels for hundreds of millions.

In connexion with insufficient technical personnel, a suggestion might be made that the Food and Agriculture Organisation should create a corps of trained technical officers and foresters. In Great Britain, at least, during the past two years, considerable numbers of young men from the Forces—far too many to be accepted in the existing space in the universities—have been applying to follow forestry courses given at the universities, and at the forestry technical schools training staff of subordinate ranks.

---

* Food and Agriculture Organisation Forestry and Forest Products. World Situation 1937–1946. Pp. 93. (Washington, D.C., 1946.)

If the Food and Agriculture Organisation took advantage of this opportunity, it might be possible to have at its disposal a trained international body able to help member governments whose forestry is very far behind the position which it should occupy. It is difficult to see how the Organisation will otherwise obtain a technical trained staff to send out to member governments; most of those with forest departments are themselves very short of staff and have considerable recruiting to do.

It has already been stated that 2,000 million hectares of forest are still left untouched, and constitute perhaps the last remaining opportunity for advancing the frontiers of modern civilization (Boyd Orr's words). These are the world's wood reservoirs; the last great bodies of renewable resources, and they must not be allowed to suffer the fate that has ravaged the forests of many older countries. To help keep them permanently productive must be one of the tasks of the Organisation. There are other tasks. "The afforestation of treeless expanses in China, south eastern Asia, the Inner and Middle East, presents a challenge so vast that only an international effort can hope to answer it. Yet here, forest restoration is the first step to stable agriculture, and to a decent nutrition level for over a thousand million people. In these regions, expanding economy and freedom from want can be little more than phrases until afforestation brings wood for fuel and forests to protect the land against erosive forces, against wind and rain, and against the hot sun. To state the world's forest problem in broad terms is not difficult. There is a shortage of wood, despite the fact that the world has more than enough forest soil to provide wood for the earth's peoples, even under an expanding economy."

On the subject of wood and its importance, and the yearly multiplication of new wood products, Boyd Orr is interesting. "In the Laboratory," he says, "under electronic microscopes, and in test tubes, wood that yesterday was looked upon only as lumber or fuel is being taken apart and its character profoundly altered. The chemical possibilities have barely been touched, and fibre chemistry is opening up an entirely new field of plastics and textiles, and permits the economic pulping of almost any wood species, and of waste from the saw mills. Large factories are being built to convert sawdust and wood unsuitable for lumber and pulp into ethyl alcohol, cattle food and chemicals. Scientists believe that they may soon duplicate in minutes what Nature took millions of years to do, and by converting wood into hydrocarbons, enable the renewable forests to augment the non-renewable reserves of oil." "Our immediate task," says Boyd Orr, "is to increase the available supply of food: our long-range task is to create a world better fed and better sheltered through a wiser use of land, and for both these tasks we must call upon an indispensable ally of agriculture—the forest."

At the present day, afforestation presents another major opportunity for creating forest values over vast areas. The denuded landscapes of south-east Asia and the Middle East, the thousands of millions of miles of desert, the continuous advance of which has never been arrested, can be transformed by tree planting, or by strict closure of large areas of scrub or savanna forest, into fertile lands, capable of supporting large populations. These should be direct profitable objectives, capable of achieving success. But the value of the forest to human welfare has other objectives, for all forests are not measurable in terms of cubic feet of timber, or producers of other marketable commodities. There are great forest influences not capable of being translated into statistical terms, but which have vast importance to the life of the earth's peoples. Even if not productive as a source of wood, forests have still an indispensable function as stabilizers of water flow, protectors of soil and agricultural crops and, especially in the tropics, as sources of food. In many regions afforestation or the maintenance of existing forests is not so much prompted by a need for local wood supplies as it is to stabilize agriculture, shelter livestock, and prevent damaging floods. In the case of wheat or corn, world production is largely a function of area planted. In the case of forests it is not so simple. Millions of acres of forest, because of their protective influences, may have little value as producers of wood, and cannot be included as contributing to the wood supplies of the world: but their loss would endanger, and in many cases destroy, agricultural values; and in some sections make human habitation impossible, as has so often been the case in past times.

A nation, therefore, in assessing its requirements in terms of forest area, must appraise its needs both in terms of forest products and of the protective influences of the forest. This need of protective forest varies with topography and geographical location, and the area required may or may not provide a sufficient quantity of forest products for national needs; but it should be regarded as the minimum to be maintained as forest in order to avoid the economic losses that attend prolonged droughts, floods and lowering of the water table. The report under notice puts the matter in a nutshell: "The world's true balance sheet, then, must take into account more than cubic metres of wood and hectares of forest per caput. The human need for forests cannot be limited to a need for raw materials. Forest policy must be directed to a dual goal—first, sufficient areas of forest to ensure the benefit of their protective influences, and second, whatever forest area may be necessary as a continuing source of raw materials for satisfactory living standards." It should be the task of the Food and Agriculture Organisation to assist governments in attaining this dual goal.

It is not possible to follow the very full statements with reference to what is termed the 'lumber situation' and the lumber shortage in different parts of the world, and the urgent requirements of timber for reconstruction purposes—house rebuilding and building purposes we may say—in most parts of the world, but the Forestry Section of the Organisation has already arrived at a very close appreciation of the seriousness of the present-day position.

The report says: "As far as pulpwood is concerned, no scarcity exists. There are sufficient amounts in the world to meet all present requirements." In Great Britain many would like to know where these amounts exist, as the rationing of paper has been one of the troubles which has probably affected the population, and especially publishers and newspapers, almost as much as the rationing of food.

Perhaps the two most interesting points, apart from the important survey of the world's forest resources and the enormous waste areas carrying neither forest nor agriculture of any value, are that more than 75 per cent of the forests now in use are cut without expert supervision, with no regard for their permanent productivity, and receive no protection against fire, and that large areas of virgin forest still remain untapped. In this connexion the Latin American forests receive very considerable notice in the report, and information never before available is disclosed.

The report puts forward some general recommendations which, summarized, deal with: legislation; the introduction of advanced sylvicultural methods; increased yields; orderly development and management of virgin forests; systematic afforestation of all denuded soils suitable for forest growth; introduction of better utilization, conversion and manufacturing methods; and the stimulation of research in the various branches of forestry, including the development of educational facilities, and the necessity of providing adequate supplies of professional foresters.

In the last paragraph it is stated: "Planned management of the world's forests and planned use of the world's forest soils is the only way to forestall the danger of temporary wood shortages and surpluses. Properly applied, F.A.O.'s world programme will ensure that the world's forests and forest products make their full and permanent contribution toward the emergence of a world free from want."

E. P. STEBBING

CALCULATING MACHINES

A DISCUSSION on calculating machines was held at the meeting of the Royal Society on March 4. In opening the discussion, Prof. M. H. A. Newman (University of Manchester) said that it would be confined to machines which are automatic, that is, require no human intervention at any stage; digital, that is, such that separate digits of each number are stored in the machine at every stage (in contrast to 'analogy' machines such as the differential analyser where the numbers are represented by directly measured physical quantities); and 'general-purpose', that is, able without modification to carry out any of a wide variety of computing jobs.

Prof. D. R. Hartree (University of Cambridge) was prevented by illness from attending, and his paper was read by Mr. P. Noble. The general ideas for a large automatic calculating machine are to be found in the designs of Charles Babbage for an 'analytical engine', published more than a century ago. It was to work by means of plungers passing through punched cards, and was to contain a 'store' for numbers, a 'mill' for carrying out arithmetical operations, and a control unit for determining the sequence of operations. The machine would at that time have had to be purely mechanical.

The main components of any digital computing machine were then described. It must have arithmetical units, such as adders and multipliers, which in electrical machines may operate in times of the order of a millisecond. There must be a store to hold numbers and instructions; an input for accepting data, and an output for furnishing final results; a means of transferring numbers between different parts of the machine; and a control mechanism which will cause the arithmetical operations to be carried out in the appropriate order. Finally, there must be means of deciding, at any stage, which of two or more alternative procedures shall be adopted, according to some given criterion. It is interesting to note that Babbage clearly recognized the importance of providing this facility.

The first large automatic digital machine built was developed by Prof. H. H. Aiken and the I.B.M. Company, and is now at Harvard. Prof. Hartree gave a brief description of its action, which is partly mechanical and partly electrical. The sequence of computing operations is specified by a punched tape, and is controlled by electric relays. In another group of machines, which have been developed largely by the Bell Telephone Laboratory, the storage is on relays, and the arithmetic is done through connexions between groups of relays. The first machine to operate with electronic circuits was the ENIAC, developed at the Moore School of Engineers at Philadelphia [see *Nature*, **157**, 527 (1946)]. It is in some ways an electric analogue of the Harvard machine. An important unit in the machine is the 'master programmer', which controls the sequence not of individual arithmetical operations but of large operations treated as units. This enables the machine to be provided with the discriminating faculty mentioned above.

Prof. Newman said that the idea of a 'universal' machine was introduced in modern times independently of Babbage's work by A. M. Turing, in connexion with certain logical problems. Automatic computing machines have been in use for some years for doing such special jobs as solving algebraic equations, factorizing large integers, making tables of a specified function, etc. A 'universal' machine is one which, when given suitable instructions, will do any of the jobs that can be done by these special-purpose machines. The machines now being made in Great Britain and the United States will be universal in this sense. In all these machines there is provision for storing numbers, say in the scale of 2, in certain places or 'houses'; and when the 'attention' of the machine is directed to certain of these rows of 0's and 1's, they are read as instructions.

For the machine to have practical utility, the number of orders set up by hand must be very much less than the number of operations to be done, or there will be no saving of time over the use of small desk-machines. This is possible owing to the recurrence in mathematical computations of the same series of operations done over and over again on different data (inductive processes). To take advantage of this, the machine has the power, when so instructed, to shift control to an arbitrary order. This is used to perform repeatedly orders number a, $a + 1, \ldots a + b$, the data in the relevant 'houses' having meanwhile changed. In order to stop the process at a suitable point, *conditional* change of control is needed, to take place if the content of a certain 'house' is positive, but not otherwise. Since exact multiplication of two n-figure numbers gives a $2n$-figure number, a stage will eventually be reached when part of the answer has to be thrown away. This leads to the accumulation of 'rounding-off' errors which, when the number of operations is large, may consume the whole answer unless precautions are taken. The difficult problems that arise in this connexion in the inversion of large matrices have been investigated by J. von Neumann and H. H. Goldstine[1], and also by A. M. Turing[2]. Reference was also made to the importance of providing methods of checking and quickly locating the causes of errors.

Dr. M. V. Wilkes (director of the Mathematical Laboratory, Cambridge) gave a description of the machine EDSAC now under construction at Cambridge. The project was started in 1946, after Dr. Wilkes had returned from attending a course at the

Moore School of Engineering in Philadelphia, where Dr. Mauchly and Dr. Eckert, designers of the ENIAC, were instructors. At that time only one type of high-speed memory was envisaged, the mercury delay-line carrying a train of pulses. The EDSAC will be a serial machine working in the scale of 2, with a capacity of 500 ten-decimal-digit numbers, some of which will act as orders. This should enable a start to be made on the applications contemplated. The machine will perform the arithmetical operations at an average rate of 15,000 a minute, assuming that 25 per cent of them are multiplications.

In view of the great advance in speed obtainable by electronic methods, Dr. Wilkes does not consider that the time has come to attempt the highest possible speeds. About two thirds of EDSAC's operating time will be spent in waiting for numbers to come out of the memory, so that an instantaneous memory with the same pulse length would be three times as quick. An upper speed limit for an electronic machine using conventional elements seems to be 6 million operations a second, 450 times the speed of EDSAC; but this figure is not in sight at present.

Prof. F. C. Williams (University of Manchester) described a method of storage he has designed, using an ordinary cathode ray tube. When a beam of cathode rays strikes an insulating surface capable of secondary emission, the potential of the spot bombarded is modified relative to the potential of the adjacent spots. Changes in the potential distribution on the inner surface of a cathode ray tube screen due to this effect give a measurable signal by capacitance coupling of an external pick-up plate. The signals depend on the change of potential distribution on the screen just before the beam was turned on—the essential requirement for a memory system. The individual digits to be stored correspond to a series of square waves applied to the brilliance control electrode, giving a row of bright spots on the screen. It has been found possible to store 32 rows of 64 dots on 12-inch diameter tubes. The two elements representing 0 and 1 are 'dot' (single spot) and 'dash', formed by adding an additional period of brilliance to the short pulse producing the dot. When this display has been 'written' in one sweep of the spot, subsequent sweeps of the beam 'read' the line by delivering signals characteristic of the pattern, namely, a negative pulse for a dot and a positive pulse for a dash.

A charge distribution on a cathode ray tube surface tends to 'spread' and leak away within about a second. This effect is neutralized by 're-writing' the record at regular intervals, short compared with the leakage time. It is proposed to devote alternate line-sweeps to reading an arbitrary line for computing purposes, and reading the lines in a regular order for regeneration purposes. Regeneration will take place every 20 milliseconds on this plan. Recognizable patterns have been set up and stored without change for periods of 4½ hours. The time-scale of the storage is 8μsec. per digit (making allowance for the time spent in regeneration). This is slower than the projected 'delay-tank' systems, but time is saved by the greater accessibility. The slower time-scale has also the advantage that the various circuits can operate more slowly, permitting some under-running of the valves.

Mr. J. H. Wilkinson (Mathematics Division, National Physical Laboratory) spoke on the machine, ACE, which is being made at the National Physical Laboratory. He compared the effective speed of mercury-tank delay line and cathode ray storage. If instructions are suitably disposed in the delay lines, and if there are some short lines holding one instruction each, there need be no waiting for the right instructions to come round. The fact that a large proportion of the operations performed are devoted to counting the lengths of induction-cycles or applying discrimination tests makes it less important that a number is stored as one of thirty-two items in a long tank; and the fact that whole sequences of numbers can be transferred by one order introduces a positive simplification in the coding.

The detailed coding, depending on the type of machine, is likely to be a small job compared with the more mathematical side of the preparation of problems; for example, arranging that the numbers involved stay in the permissible range. By preliminary work of the kind now being done at the National Physical Laboratory, it is hoped to reduce this mathematical part of the preparatory work by providing standard units which can be inserted whole into larger routines. Practical numerical investigations are being carried out with ordinary desk machines, which often reveal difficulties that might otherwise be overlooked.

Mr. J. D. Booth described a parallel-operation machine which is in course of construction at Birkbeck College, in which the storage is a rotating magnetic drum, having a capacity of about 4,000 numbers, each of forty digits. Mr. Aughtie (Mathematics Division, National Physical Laboratory) spoke on the problem of input and output, namely, loading the machine with the data and instructions for a problem, and extracting the final answer in convenient form.

A detailed report of the discussion will be published in the *Proceedings of the Royal Society* in due course.

OBITUARIES

Prof. James McIntosh

MANY readers will have learned with regret of the death of Prof. James McIntosh, which occurred on April 5 at his home in Aberdeen. He was at the time of his death professor of pathology in the University of London and director of the Bland-Sutton Institute of Pathology, at the Middlesex Hospital, a post which he had held since 1920.

The purpose of an obituary notice is to give the reader a picture of the man as he was when at work, and to try to give some idea of his personality. The formal facts of McIntosh's career can always be found in standard works of reference, and therefore only a brief summary need be given here. He was born in Aberdeen and educated at the Robert Gordon College and at the University of Aberdeen, where he qualified in 1905 after a brilliant career as a student. In 1906 he was awarded the Alexander Anderson Scholarship, and this enabled him to spend the next two years at the Pasteur Institute working under Levaditi. It was here that his life-long interest in virus diseases first became aroused.

McIntosh's first studies were concerned with the etiology and chemotherapy of syphilis. He began these in Paris and continued them on his return to

Aberdeen and later at the London Hospital, where he worked in collaboration with Fildes. He also carried out some work on the etiology of acute anterior poliomyelitis. During the First World War he did invaluable work on the isolation, recognition and classification of the anaerobic bacteria of war wounds, and the results were outlined in a special report to the Medical Research Committee. His interest in virus diseases continued after his appointment as director of the Bland-Sutton Institute, and he made a special study of the virus infections of the central nervous system. The experiments of Gye and Barnard on the Rous filterable sarcoma turned his attention to the possible connexion between virus infection and cancer. His most important work in this direction was the production of filterable tumours by means of chemical carcinogens. This work may prove to be of the greatest significance and, in fact, to be a turning point in the history of cancer research.

In appearance McIntosh was a shortish man with black hair turning to grey in later years, with slightly rounded shoulders, which he himself attributed to having spent the greater part of his life looking down a microscope. He had a curious offhand way of speaking which gave the mistaken impression that he was not particularly interested in what one was saying. This characteristic was displayed at meetings, when he would apparently go off at a tangent and introduce what seemed to be a lot of irrelevant material. Frequently his points would be dismissed as being of no importance; but almost invariably McIntosh would come back and secure a complete victory for his views, before his opponents had realized what had happened. At scientific meetings he gave the impression of being difficult; but people in his own laboratory were always struck with his kindness to them and knew they could rely on his continued help and interest.

In conclusion, one must say that McIntosh's scientific career was a stormy one, as he wished it to be. But in whatever he touched, however, whether it be vaccinia, anaerobes, syphilis or the etiology of malignant disease, he stirred up a controversy necessitating a great deal of experimental work, and this work will go on for a very long time. E. C. DODDS

WE regret to announce the following deaths:

Dr. Vaughan Cornish, president in 1928 of the Geographical Association, on May 1, aged eighty-five.

Dr. J. G. Parker, sometime principal of the Leathersellers' Technical College, London, honorary secretary during 1897–1912 of the International Association of Leather Trades' Chemists, on April 30, aged seventy-eight.

NEWS and VIEWS

Plant Breeding Institute, Cambridge

BY agreement between the University of Cambridge, the Ministry of Agriculture and the Agricultural Research Council, it has been decided that, as soon as conditions become favourable, the Plant Breeding Institute at Cambridge shall be transferred from its existing site on the University Farm to one offering greater facilities to an increased staff. When the move is made, management by the University will be transferred to an independent body comparable with those which govern such agricultural research institutes as Rothamsted and East Malling. Meanwhile, the Plant Breeding Institute will remain attached to the School of Agriculture at Cambridge as at present. The future expansion in plant breeding which is envisaged is a notable part of the general programme of development of agricultural research in Great Britain, financed by the Ministry of Agriculture in consultation with the Agricultural Research Council. The Institute will concern itself with the full range of arable and pasture crops grown in the eastern and drier parts of Britain, although the interests of other regions in certain crops will not be neglected. It already handles wheat, barley, oats, potatoes, sugar beet, beans, peas, lucerne and sainfoin, and in addition to expanding the work on these crops, others such as rapes, kales and certain herbage plants will be included. Fundamental breeding problems are envisaged as an important part of the Institute's programme in the future.

Since the Cambridge Plant Breeding Institute was established with Sir Rowland Biffen as first director, several new varieties of crop plants, which are now well known and commercially successful, have been produced, including 'Little Joss' and 'Yeoman' wheats (by Sir Rowland Biffen), 'Holdfast' and 'Steadfast' wheats (by Sir Frank Engledow), and 'Picton' oat and 'Camton' barley (by Dr. H. Hunter). Sir Rowland Biffen was succeeded as director by Dr. Hunter, who retired in 1946. Dr. G. D. H. Bell was then appointed acting director and he has now been confirmed as director of the Institute, which, as indicated above, is to be expanded and established as a separate research organisation.

Dr. G. D. H. Bell

DR. BELL, the new director of the Plant Breeding Institute, is a fellow of Selwyn College and University lecturer in agricultural botany, and has been a member of the staff of the Plant Breeding Institute since 1932. He received his early scientific training at University College, Bangor, whence he obtained an agricultural scholarship for postgraduate study in genetics and plant breeding at Cambridge and in the United States. He has travelled extensively in western and northern Europe and in the West Indies. His teaching duties are now confined to lecturing to graduate classes on agricultural botany, with particular reference to problems of crop improvement; but these teaching duties will be reduced as his responsibilities as director of the Plant Breeding Institute increase. He will shortly publish a book on "Cultivated Plants of the Farm". His investigations have been centred on the breeding of barley, field peas and sugar beet; but he is now also interested in wheat and oats. He has produced two new varieties of barley, already on the market, 'Prefect' and 'Pioneer', the latter being the first winter-hardy malting barley to be bred in Great Britain. Much of his time during the War was occupied with problems concerning sugar beet. With regard to general crop improvement in Britain, he is anxious to increase the effective range of varietal types so that the area of successful cultivation can be increased. This involves the creation of a wider range of varieties adapted to particular environments. Last summer he organised very successfully at Cambridge the first conference of British directors of plant breeding institutes and their staffs. He has published papers on plant breeding, developmental studies in relation to yield, the classification of barley varieties, inheritance in barley, and vernalization in cereals. He has been a regular contributor to the *Journal of the Royal Agricultural Society* for many years.

New Vegetable Research Station: Dr. J. Philp

Dr. James Philp has been appointed director of the Vegetable Research Station to be set up in due course in Britain. He will serve on the staff of the Ministry of Agriculture until the governing body of the new Station is legally constituted and will at first be engaged on the search for a suitable site. Dr. Philp was educated at the Universities of Glasgow and London. He was a cytogeneticist on the staff of the John Innes Horticultural Institution, Merton, during 1927–34. He then became director of the Cereal Division of the Egyptian Ministry of Agriculture. In 1942 he was appointed forest geneticist with the South African Department of Forestry, and established a tree-breeding station. He has been director of the South African Wattle Research Institute (which he established) at Pietermaritzburg from 1944 until 1947. Dr. Philp is the joint author with Dr. F. W. Sansome of "Recent Advances in Plant Genetics", and the author of many scientific papers on agricultural and horticultural plants and on trees.

Chemistry at the University of Liverpool: Dr. C. E. H. Bawn

Dr. C. E. H. Bawn, who has been appointed to the Grant–Brunner chair of physical and inorganic chemistry in the University of Liverpool, is a Bristolian who graduated and carried out his first researches at the University of Bristol. His first university appointment was as assistant lecturer at the University of Manchester in 1931, where he owed much to the inspiration of Prof. M. Polanyi, under whom he worked on alkali metal flames and on the theory of chemical kinetics. He returned to Bristol in 1938 as a lecturer in physical chemistry and became reader in 1945. During the War he was engaged on extra-mural work for the Ministry of Supply, mainly on problems arising from the manufacture of explosives, and in 1943 was appointed principal scientific officer in charge of a physico-chemical section in the Armament Research Department, Ministry of Supply. Dr. Bawn's interest in research lies in chemical kinetics. During the War he carried out pioneer work on the stability and kinetics of decomposition of high explosives and pyrotechnics, evolving special technique for the purpose. His main work has, however, been based on the chemistry of free radicals, studying their methods of production and stability and the kinetics of their reactions. He has advanced our knowledge of biradicals, and of the decomposition of metal alkyls. Recently he has extended his work to the kinetics of polymerization reactions, particularly on the initiation of polymerization by free radicals, and has written a book on polymerization shortly to be published.

Theoretical Physics at Liverpool: Dr. H. Fröhlich

The appointment of Dr. H. Fröhlich to the chair of theoretical physics at the University of Liverpool has recently been announced. Dr. Fröhlich has been associated with Prof. N. F. Mott since 1935 in building up the school of theoretical physics at Bristol. He has specialized in nuclear physics, where he has made important contributions to the theory of the meson and to nuclear binding forces, and on dielectrics, where his work on the mechanisms of breakdown and loss are well known. In the latter field Dr. Fröhlich has been prominent in developing those parts of theoretical physics of interest to industry, and has taken a large part in the well-known Bristol 'summer schools'; his knowledge of nuclear physics, also, makes him particularly fitted to collaborate with the group at Liverpool working under Sir James Chadwick.

Chemistry at University College, Dundee: Dr. D. H. Everett

The chair of chemistry at University College, Dundee, which became vacant last year when Prof. Wynne-Jones went to King's College, Newcastle-upon-Tyne, has been filled by the appointment of Dr. D. H. Everett, fellow of Exeter College, Oxford. Dr. Everett was educated at the University of Reading under Prof. Wynne-Jones, and his first research work was done there and at Dundee on the electrochemistry of non-aqueous solutions. In 1939 he was elected to a Ramsay fellowship and went to Balliol College, Oxford, to work on reaction kinetics with Mr. R. P. Bell. This programme was interrupted by the War, and Dr. Everett took an active part in scientific war-work, at first in a team of workers in Oxford and later in other fields of work which took him eventually to India. He returned to Oxford with an Imperial Chemical Industries fellowship, and after a short period as a lecturer in Dundee was elected to an official fellowship at Exeter College, Oxford, in 1947. He has already done distinguished work on the physical chemistry of both aqueous and non-aqueous solutions, and will thus continue the tradition established by Prof. Wynne-Jones in Dundee.

Scientific Research (Defence): Dr. F. J. Wilkins

Dr. F. J. Wilkins has been appointed principal director of scientific research (defence) in succession to Dr. E. T. Paris. Under the Controller of Supplies (Munitions) and the Chief Scientist, he will be responsible for research on munitions and allied equipment. Dr. Wilkins joined the Ministry of Supply from Imperial Chemical Industries, Ltd., in 1941, and was appointed regional development officer (western region) for the Royal Ordnance filling factories. In 1944 he was appointed assistant director of Filling Factories and later deputy chief superintendent of armament research at the Ministry. Since April 1946, he has been director of chemical research and development.

Meldola Medal, 1947: Dr. J. Baddiley

On the recommendation of the Council of the Royal Institute of Chemistry, the Society of Maccabæans has awarded the Meldola Medal for 1947 to Dr. James Baddiley in recognition of the outstanding contributions he has made to knowledge in the field of nucleoside chemistry and related subjects. Educated at the Manchester Grammar School, Baddiley proceeded to the University of Manchester. Work with Prof. A. R. Todd on a synthetic approach to the study of nucleosides involved the development of new methods for the synthesis of purines and their 9-substituted derivatives and a general, unambiguous synthesis of 9-glycosidopurines. Application of these methods to the synthesis of 9-*d*-ribosidoadenine gave a product which differed only in the size of the sugar ring from the important naturally occurring nucleoside adenosine. He was awarded the degrees of M.Sc. (1942) and Ph.D. (1944) of the University of Manchester on the results of these investigations. After a period of work on penicillin chemistry under a grant from the Medical Research Council, he was awarded an I.C.I. fellowship and resumed work with Prof. Todd at Cambridge on the chemistry of the nucleotides, particularly those possessing coenzyme function. By the application of a new phosphorylating reagent, dibenzyl chlorophosphonate, muscle adenylic acid and adenosine diphosphate were synthesized from adenosine in good yield, thereby enabling these important biological substances to become more accessible for biochemical study and, at the same time, proving their structures beyond doubt. Since then, Dr. Baddiley has been engaged on a total synthesis of adenosine triphosphate and is at present spending a year at the Wenner Grens Institut, Stockholm, to extend his knowledge of nucleotides on the biological side and to acquire tracer technique for his future investigations. The Meldola Medal is the gift of the Society of Maccabæans and is normally awarded annually to the chemist who, being a British subject and less than thirty years of age, shows the most promise as indicated by his or her published chemical work.

Royal Society of Edinburgh : Awards

The council of the Royal Society of Edinburgh has awarded the Keith Prize for the period 1945–47 to Dr. Charlotte Auerbach, of the Institute of Animal Genetics, University of Edinburgh, for her contributions to genetics published in the Society's *Proceedings*, during the period of the award and previously. The Neill Prize for the period 1945–47 has been awarded to Dr. Robert Broom, for his contributions to our knowledge of the fossil vertebrates of the Karroo Beds of South Africa. At the ordinary meeting of the Society held on May 3, David Anderson-Berry Prizes were presented to Dr. Ralston Paterson, director of the Holt Radium Institute, Manchester, for his book on radiotherapy; and to Dr. P. C. Koller, of the Royal Cancer Hospital, London, for his researches on the effect of radiation by X-rays on experimental and pathological material.

Royal Institute of Chemistry : Anniversary Meeting

For the first time in the history of the Royal Institute of Chemistry, the annual general meeting was held this year outside London, the Birmingham and Midlands Section of the Institute having invited the Council to hold the anniversary meetings in Birmingham during April 15–17. An exhibition entitled "The Chemist in the Midlands", which was opened by the president of the Institute, Dr. G. Roche Lynch, on April 15 at the Central Technical College, afforded a remarkable demonstration of the present-day activities of chemists in research, industrial production and the public services in the Midlands, and of the organisation and development of scientific and technical education and research in the area. The exhibition was open to the public during the following two days and special arrangements were made for visits by parties of school-children. Later the officers of the Institute received a civic welcome from the Deputy Mayor of Birmingham (Alderman A. F. Bradbeer). The general proceedings of the meeting included a lecture by Prof. R. P. Linstead on "The Chemical Research Laboratory, Teddington", and a lecture by Prof. M. Stacey on "The New Fluorocarbon Chemistry". At the annual general meeting, two special resolutions, moved by the president, were passed: one authorizing the Council to submit to the Privy Council a petition for a new charter for the Institute; the other consenting to the raising, as from January 1, 1949, of the annual subscriptions of fellows and of associates. The following were elected officers for 1948–49: *President:* Dr. Gerald Roche Lynch; *Vice-Presidents:* Prof. H. V. A. Briscoe, Prof. F. Challenger, Mr. G. E. Dodds, Prof. Alexander Findlay, Mr. E. T. Osborne, Mr. A. J. Prince; *Hon. Treasurer:* Dr. D. W. Kent-Jones.

American Awards to British Scientific Workers

The United States Military Attaché in London, Major-General Clayton L. Bissell, presented United States awards and decorations to eighteen British citizens, one Canadian and one Australian, on April 29, for services during the Second World War. Among the awards were the following: *Medal of Freedom with Silver Palm:* Prof. S. Zuckerman, professor of anatomy, University of Birmingham, scientific adviser to the Deputy Commanding General of Allied Force Headquarters and to Supreme Headquarters Allied Expeditionary Force, from January 1943 until May 1945; *Medal of Freedom:* Prof. W. Norman Thomas, professor of engineering, University College, Cardiff, head of the *RE*2/4 Division of the Research and Experiments Department, Ministry of Home Security; *Bronze Star:* Miss Peggy Furse, civilian personnel officer, Personnel Section, Psychological Warfare Division, Supreme Headquarters Allied Expeditionary Force (Rear Echelon), from March 1944 until July 1945.

Royal Botanic Gardens, Kew : Recent Acquisitions

Mr. W. R. Sherrin has presented to the Herbarium of the Royal Botanic Gardens, Kew, his valuable collection of bog-mosses (*Sphagnum*). The material occupies two standard-sized cabinets, and the specimens, representing approximately 4,350 separate collectings, are mounted on 1,360 sheets. The specimens have been determined with the utmost care and largely formed the basis of Mr. Sherrin's "Illustrated Handbook of the British Sphagna", published by Taylor and Francis, London, in 1927. The *Sphagna* are of considerable interest to botanists for a number of reasons and they also have economic importance. The genus is a large one (Warnstorff, in 1911, accepted 342 species, some with a considerable number of varieties and forms) and occurs all over the world; but the species thrive best in the damp, humid climates of the temperate zone in Europe, Asia and America. Typically, the species grow in bogs and other wet places where the water is more or less acid, often very highly acid. Their dead remains play an important part in the building up of the masses of peat filling such bogs. Newly dried *Sphagnum* has been used for packing material, fo making coarser kinds of paper, in horticulture, and in the manufacture of molasses feeds for livestock Taxonomically the genus is a difficult one. The differences used as key characters are often either difficult to define precisely in words or are microscopic. This enhances the value of such a collection as that made by Mr. Sherrin, which at Kew will be accessible to all *bona fide* research students.

Palæontographical Society Annual Meeting

THE hundred and first annual general meeting of the Palæontographical Society was held in the apartments of the Geological Society, London, on April 27, under the chairmanship of Prof. H. L. Hawkins, president. Following the resignation of Dr. C. J. Stubblefield from the office of secretary after fourteen years service, it was considered that the routine financial duties which for many years have been undertaken by successive secretaries should devolve upon the treasurer. Since, however, the present treasurer was unable to take over additional responsibilities, his offer to resign was accepted. The meeting then elected Mr. L. Bairstow, of the British Museum (Natural History), as treasurer, and Mr. R. V. Melville, of H.M. Geological Survey and Museum, as secretary. The new members of council elected were Dr. A. J. Bull, Mr. C. P. Chatwin, Mr. M. A. C. Hinton and Dr. C. J. Stubblefield in place of Messrs. C. H. Dinham, G. A. Kellaway, R. V. Melville and Dr. Vernon Wilson. In view of the increased cost of printing, it was decided that all annual volumes, of whatever date, will now be charged at £2 2*s*., except for the volume sent to members in the year of issue, which will remain at one guinea, or £1 2*s*. 6*d*. if delivered overseas. The prices of publications issued before 1919 will be double those given in the Society's list dated November 1947. Except for the annual volumes, the prices of publications issued after 1918 will remain as listed, and members will receive, as hitherto, discount on past publications ordered through the secretary.

"Precise Measurement for Engineers"

"PRECISE Measurement for Engineers" is the first of a group of films which is being produced to illustrate the relationship of the work of the various divisions of the National Physical Laboratory to industry, as part of a series arranged by the Department of Scientific and Industrial Research under the general title of "Science in the Service of the Nation". The film shows the part played by the Metrology Division of the National Physical Laboratory in the field of precise measurement for engineers and is designed to portray the scientific basis of interchangeable engineering production. The film opens with views in a factory in the Midlands in which agricultural tractors are being produced in large quantities, the emphasis being on accuracy in the size of components and the significance of tolerance limits. The film illustrates the checking of size, (1) by means of limit gauges and (2) by measurement under a system of quality control. It then shows the importance of standardizing gauges and measuring equipment in the factories to secure universal interchangeability of components, and how this standardization depends ultimately upon the work at the National Physical Laboratory, where, in the Metrology Division, standards of length suitable for engineers are derived from the Imperial Standard Yard. The film also demonstrates the work of the Metrology Division over a large range of precise measurement, including that of screw gauges, gears, surface finish and the measurement of angles.

Summer School in Relaxation Methods

IN the long vacation of the last three years, Summer Schools in 'Relaxation Methods' have been held at the Imperial College of Science and Technology, London, S.W.7. Their success has encouraged the provision of a similar course in the coming long vacation, and this is now planned for the four weeks July 6–30. It would seem that there is no great difficulty in acquiring such knowledge of the relaxational technique as is required to solve ordinary engineering problems (frameworks, electrical networks, etc.), but that for partial differential equations in two independent variables, although techniques have been described in published papers, these have necessarily been made too concise to meet the needs of readers working without supervision. Accordingly, it is proposed to concentrate on problems of this second kind. The course will consist of more or less formal lectures with numerous examples to be solved under supervision. Lectures will be given on Tuesdays–Fridays only, with facilities for practical work on Mondays; the inaugural lecture will be delivered on July 6. Further particulars can be obtained from D. N. de G. Allen, Imperial College, London, S.W.7.

Royal Institution

THE anniversary meeting of the members of the Royal Institution was held on May 1, Lord Brabazon, president, in the chair. The annual report of the visitors was received and adopted at the meeting. The following officers were elected: *President*, Lord Brabazon of Tara; *Secretary*, Prof. A. O. Rankine; *Treasurer*, Dr. R. E. Slade; *Managers*, Prof. E. N. da C. Andrade, Prof. H. V. A. Briscoe, Prof. H. Dingle, Dr. P. Dunsheath, Sir Alfred Egerton, Dr. E. V. Evans, Sir William Halcrow, Prof. F. L. Hopwood, Prof. L. C. Martin, Sir Clifford Paterson, Prof. H. J. Plenderleith, Sir Geoffrey Taylor, Sir George Thomson, Prof. A. M. Tyndall, Mr. Frank Wakeham. *Visitors*, Mr. J. J. Abraham, Lieut.-Colonel S. J. M. Auld, Dr. J. H. Brinkworth, Dr. H. E. Cox, Mr. F. P. Dunn, Dr. H. J. T. Ellingham, Dr. A. T. Fraser, Dr. R. E. Gibbs, Mr. A. C. Hartley, Mr. J. Henshilwood, Dr. D. C. Martin, Mr. D. Northall-Laurie, Dr. E. Talbot Paris, Mr. J. W. Ryde, Dr. H. Shaw.

Announcements

THE American Association for the Advancement of Science celebrates its centenary this year; the meeting will be held at Washington, D.C., during September 13–17.

THE National Physical Laboratory at Teddington is having an 'Open Day' on June 21, 2.30–6.0 p.m., to which representatives of industrial organisations are being invited. Although the wide range of scientific research and investigation undertaken at the Laboratory is already well known to industry, there may still be a number of firms with which it has no contact. A number of invitations is accordingly being reserved to enable such firms to visit the Laboratory. Accredited representatives of industrial organisations are invited to apply to the Director, National Physical Laboratory, Teddington, Middlesex, not later than June 5.

DR. KENNETH CARTER, recently research liaison officer and secretary to the Therapeutic Research Corporation of Great Britain, Ltd., has been made a director of Laboratorios Glaxo (Argentina) S.A., and will reside in Buenos Aires.

Curare-like Action of Polymethylene *bis*-Quaternary Ammonium Salts

TUBOCURARINE chloride is a *bis*-tetrahydro*iso*quinoline alkaloid containing two quaternary nitrogen atoms[1], and its extraordinary potency in blocking neuromuscular transmission, compared with that of simple quaternary ammonium salts, might conceivably be due in part to the presence of two such cationic groups at some optimal distance apart. With this in mind, we have prepared and tested for curare-like activity a number of simple *bis*-quaternary ammonium salts in which the nitrogen atoms were separated by polymethylene chains of different lengths.

Among the salts prepared were polymethylene *bis*-trimethyl- and *bis*-triethyl-ammonium dibromides with chain-lengths of from two to five and seven to thirteen carbon atoms, and a smaller group of polymethylene *bis*-quinolinium and *bis*-strychninium dibromides; they were obtained by heating polymethylene dibromides with the appropriate tertiary bases, and were tested on the phrenic nerve-diaphragm preparation of the rat.

In the *bis*-trimethylammonium series, the ethylene member (C_2 chain) was about twice as active as tetramethylammonium; it might be considered to contain twice the number of effective blocking groups per molecule. The salts with C_3, C_4 and C_5 chains were only feebly active; but there was a progressive rise in activity from the C_7 to the C_9 member; activity remained fairly constant from C_9 to C_{12} and fell slightly at C_{13}. In the *bis*-triethylammonium series activity rose steadily from C_4 to C_{13}, the last member being more active than the *bis*-trimethyl C_9 member. None of these compounds was more than two-fifths as active as tubocurarine chloride.

Superficially, these results suggest that the *bis*-quaternary salts behave rather like the analogous mono-quaternary salts containing an alkyl group with (to the nearest whole number) half the number of carbon atoms in the polymethylene chain; thus in the series $Me_3N.C_nH_{2n+1}$, the least active on frog muscle are those in which $n = 2$ or 3, and cations in which $n = 4$ to 8 are all about as active as tetramethylammonium[2]; in the series $Et_3N.C_nH_{2n+1}$, activity on frog muscle increases steadily from $n = 2$ to $n = 8$[3]. However, it is doubtful whether it is legitimate to compare activities on a rat preparation with those on frog preparations.

The *bis*-quaternary ammonium salts display quite different activities in the rabbit head-drop test: in the *bis*-trimethyl series, activity rose to a pronounced maximum in the C_{10} member and fell slowly as the carbon chain was increased beyond ten carbon atoms. The C_{10} member was about three times as potent as tubocurarine chloride, 0·08 mgm./kgm. being required to produce head drop, compared with 0·26 mgm./kgm. of *d*-tubocurarine chloride. The approximate activities of the C_8 to C_{13} members in terms of tubocurarine chloride as 1 were: C_8, 0·3; C_9, 0·9; C_{10}, 3·3; C_{11}, 0·4; C_{12}, 0·3; C_{13}, 0·3. Not all our compounds have yet been tested by this method, but it is quite clear that the relative activities, and their variation within a homologous series, may be quite different in the rat diaphragm and the rabbit head-drop tests.

Nearly all the *bis*-quaternary ammonium salts produce augmentation of the contractions of the rat diaphragm, usually at concentrations slightly lower than those needed to produce inhibition. With ethylene *bis*-strychninium dibromide it was possible to observe augmentation at low doses, inhibition at higher doses and to find an intermediate dose at which the two effects cancelled each other. This augmentation resembles superficially the effect of anticholinesterase drugs, and consequently representative members were tested on the cholinesterase of caudate nucleus (dog), with acetylcholine as substrate. All the *bis*-quaternary salts so far tested in this way showed some inhibition of the enzyme at concentrations slightly lower than those needed to reduce the contractions of the rat diaphragm (10^{-8} to 10^{-5} molar); this inhibition was particularly striking in the C_{10}-*bis*-quinolinium and C_{13}-*bis*-triethylammonium salts, and less marked in the C_9-*bis*-trimethylammonium salt. Tetramethylammonium did not inhibit this enzyme, although augmentation was sometimes observed with this cation in the rat diaphragm preparation.

Our thanks are due to Dr. N. K. Dutta, who carried out the rabbit head-drop tests.

[3] Kulz, F., *Pflügers Arch.*, 195, 623 (1922).

DURING a test of octamethylene-$\alpha\omega$-*bis*-trimethylammonium chloride for the power of liberating histamine, it was observed to be remarkably effective as a cause of neuromuscular block. Accordingly, a series of straight-chain aliphatic $\alpha\omega$-*bis*-trimethylammonium iodides have been synthesized from diamines by treatment in methyl alcoholic solution with methyl iodide and sodium hydroxide, and using the insolubility of these compounds in acetone, and the solubility of sodium iodide in this solvent for their isolation. All the compounds synthesized were tested for potency, and the octamethylene derivative (C_8) was the subject of more detailed pharmacological study.

In the rabbit head-drop test for curare-like activity, potency increased from the ethylene derivative to the octamethylene derivative, and the decamethylene derivative (C_{10}) was more potent still, 0·11 mgm./kgm. of the iodide being required to produce head-drop, compared with 0·25 mgm./kgm. of *d*-tubocurarine chloride. The potency in relation to *d*-tubocurarine chloride varied, however, with the test object; thus, the approximate ratio of an effective dose of the C_8 derivative to an equipotent dose of *d*-tubocurarine chloride was, on the cat's tibialis, ⅓; on rabbit's head-drop, 3; on frog nerve-sartorius preparation, 3; on rat's diaphragm preparation, 50–100. In the cat's tibialis preparation[1], the C_8 derivative prevented the response of the muscle to stimulation of its motor nerve and to close arterial injection of acetylcholine, but not its response to direct stimulation. The conduction of impulses in nerve trunks was not affected by it.

While large doses of the C_8 derivative caused rapid neuromuscular block, moderate doses injected intravenously in the cat initially increased the response of tibialis to single maximal shocks applied to the motor nerve, and this response was followed by a small prolongation of the contraction, together with a widespread fibrillation of the musculature for 20–30 sec. not unlike that resulting from the injection of anticholinesterases. Intra-arterial injection of the C_8 derivative in a dose of 20 μgm. into the cat's tibialis itself produced a twitch before block ensued. The curare-like action was not antagonized by prostigmine in doses adequate to antagonize the effect of *d*-tubocurarine chloride, either in the cat's tibialis or in the rabbit's head-drop test.

Comparison of potency with *d*-tubocurarine chloride was complicated by the remarkable finding that while *d*-tubocurarine chloride is unaltered in potency when given after these *bis*-quaternary salts, the converse is not true; thus, following the injection of two-thirds head-drop dose, approximately twice as much of the C_{10} derivative was required to produce head-drop as was normally needed.

The results reported represent preliminary findings on a series of simple compounds, some of which have a potency which exceeds that of *d*-tubocurarine chloride. They serve to demonstrate, however, the importance of pharmacological testing of possible substitutes for *d*-tubocurarine chloride on more than one test object, and to suggest that before clinical application can be considered it is desirable to find some satisfactory antagonist to their effects.

We are much indebted to Dr. H. King, who synthesized the first compound tested, and to Dr. F. C. MacIntosh for their encouragement and advice.

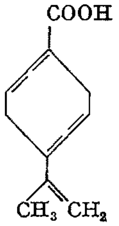
Antibiotic Substances from the Heart Wood of *Thuja plicata* Don.

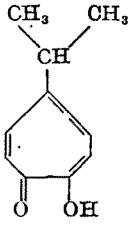
THE heart-wood of western red cedar (*Thuja plicata* Don.), which possesses a low specific gravity and is very resistant towards decay, has been examined by Anderson and Sherrard[1]. The steam distillate of this wood furnished an acid, $C_{10}H_{12}O_2$, termed dehydroperillic acid, showing low toxicity, and a very toxic 'phenol', m.p. 82°, of the same composition. For dehydroperillic acid they suggest the formula (I), but the structure of the compound of m.p. 82° was not elucidated.

In a private communication Anderson describes the separation of the 'phenolic' fraction of the steam distillate into the above compound, m.p. 82°, and an oil, also $C_{10}H_{12}O_2$, which he has kindly given us the opportunity to examine. It had meanwhile partly crystallized and afforded a compound, $C_{10}H_{12}O_2$, m.p. 52–52·5°, the investigation of which will be described jointly with Dr. Anderson.

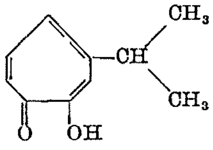
From *Thuja plicata*, grown in Sweden, we have isolated dehydroperillic acid, the compound, m.p. 82°, and a less acidic isomeride, m.p. 34°, but none of the isomeride, m.p. 52–52·5°. The ultra-violet absorption spectrum of dehydroperillic acid shows maxima at 220 and 280 mμ. This behaviour suggests a structure with a more extended conjugated system than that in (I).



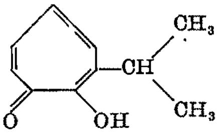
I



II



III



IV

The ultra-violet absorption spectra of the three isomerides, melting points 82°, 52–52·5° and 34° respectively in alcoholic solution, are very similar, with maxima at 230–240 mμ and broad absorptions between 320 and 370 mμ. These isomerides absorb four moles of hydrogen on catalytic hydrogenation. The compound, m.p. 82°, thereby yields a diol, $C_{10}H_{20}O_2$, m.p. 87–88°, and as a by-product an oil, probably a diastereoisomeride or a mixture of such. The two other isomerides only give oily hydrogenation products. The diol, m.p. 87–88°, is easily cleaved by periodic acid to a dialdehyde, $C_{10}H_{18}O_2$, characterized as its *bis*-2 : 4-dinitrophenylhydrazone, m.p. 194–195°. Oxidation with potassium permanganate yields a dicarboxylic acid, $C_{10}H_{18}O_2$, m.p. 65·5–66·5°. The barium salt of this acid on dry distillation afforded 1-*iso*propyl*cyclo*hexanone-(4), identified as the 2 : 4-dinitrophenylhydrazone, m.p. 118–119°, and semicarbazone, m.p. 188–189°; both melting points were undepressed on admixture with authentic specimens. Hence the dicarboxylic acid, m.p. 65·5–66·5°, must be γ-*iso*propylpimelic acid. Consequently, the compound, m.p. 82°, most probably possesses the structure (II). This conclusion is supported by the fact that oxidation of the compound, m.p. 82°, with chromic acid furnished *iso*butyric acid (*p*-bromophenacyl ester, m.p. 76–77°; mixed m.p. 76–77°).

The absorption spectra and other evidence make it probable that the compounds, m.p. 52–52·5° and m.p. 34°, are represented by the formulæ (III) and (IV) respectively.

The compound, m.p. 82°, is termed γ-thujaplicin because the *iso*propyl group occupies the γ-position in the *cyclo*heptatrieneolone. If our views on the structure of the compounds, m.p. 52–52·5°, and m.p. 34°, are confirmed, these should be termed β- and α-thujaplicin respectively. The structure proposed for γ-thujaplicin recalls the constitution of the azulenes, stipitatic acid according to Dewar[2], and purpurogallin according to Prof. R. D. Haworth, and to Dr. J. A. Barltrop (private communications).

Separation and Identification of Methylated Sugars on the Paper Chromatogram

THE identification of the products of hydrolysis of a methylated polysaccharide composed of many different sugar residues is a tedious and difficult task, especially when the polysaccharide is available only in small quantities. We have found, however, that many of the methylated sugars can be readily separated and identified on the paper chromatogram, using the same apparatus and solvents as described for the separation of the simple sugars[1,2]. The chromatogram is allowed to run until the solvent has advanced about 40 cm. from the starting line. The paper is then dried and sprayed with ammoniacal silver nitrate, and on warming, the positions of the sugars are indicated by brown spots (except in the case of tetramethylfructopyranose, which reduces ammoniacal silver nitrate only very slightly). As a standard, we use tetramethyl *D*-glucose, which moves rapidly on the chromatogram. The distance the sugar travels is measured from the starting line to the centre, not the edge, of the sugar spot, since the size of the spot and its leading edge vary with the concentration of sugar solution used. The figure R_G given in the accompanying table refers to the ratio between the distance the sugar travels and the distance through which the tetramethyl *D*-glucose has moved. (We use this in preference to the R_F value, which tends to vary with the distance the sugar has advanced from the starting line.)

Substance	R_G	Substance	R_G
Galactose	0·075	2 : 3-Dimethyl arabinose	0·63
Arabinose	0·135	2 : 3 : 4-Trimethyl galactose	0·64
Xylose	0·15	2 : 4-Dimethyl xylose	0·66
4-Methyl galactose	0·165	2 : 4 : 6-Trimethyl galactose	0·67
6-Methyl galactose	0·185	2 : 3-Dimethyl xylose	0·74
Talose, lyxose	0·19	2 : 4 : 6-Trimethyl glucose	0·755
2-Methyl galactose	0·205	3 : 4 : 6-Trimethyl mannose	0·795
Ribose, fucose	0·21	2 : 3 : 6-Trimethyl glucose	0·805
3-Methyl glucose	0·265	2 : 3 : 4 : 6-Tetramethyl galactose	0·88
Rhamnose	0·30	Tetramethyl fructopyranose	0·90
3 : 4-Dimethyl galactose	0·32	2 : 3 : 4-Trimethyl xylose	0·94
2-Methyl arabinose	0·36	2 : 3 : 5-Trimethyl arabinose	0·95
3 : 6-Anhydroglucose	0·37	2 : 3 : 4 : 6-Tetramethyl mannose	0·96
2-Methyl xylose	0·385	2 : 3 : 4 : 6-Tetramethyl glucose	1·0
2 : 4-Dimethyl galactose	0·405	2 : 3 : 4-Trimethyl rhamnose	1·01
2-Methyl fucose	0·51	Raffinose	0·0*
3 : 6-Dimethyl glucose	0·51	Sucrose	0·035
4-Methyl rhamnose	0·575	β-Methyl arabinoside	0·325
3 : 4-Dimethyl mannose	0·58	α-Methyl mannoside	0·30

* No movement.

The separation of the tetramethyl derivatives of glucose, galactose and mannose is readily achieved. Furthermore, closely related pairs of substances, for example, 2 : 3-dimethyl xylose and 2 : 4-dimethylxylose, and 2 : 3 : 4-trimethyl galactose and 2 : 4 : 6-trimethyl galactose, are separable. The method renders practicable a rapid examination of the hydrolysis products obtained from small quantities of methylated polysaccharides. It will facilitate also the examination of fractions of methylated sugars produced on distillation of the products of hydrolysis of methylated polysaccharides. The presence of methylated uronic acid derivatives causes tailing on the paper chromatogram; but we find that if these are first removed with 'Amberlite Resin', 1*R*4*B*, the spots due to the various sugars may be readily differentiated in the majority of cases.

By this method we have confirmed the presence of the methylated sugar derivatives detected by the distillation procedure in methylated cherry gum[3], slippery elm mucilage[4] and sugar beet araban[5], and in some instances have found indications of the presence of other sugar derivatives. For example, 2-methyl galactose and 3 : 4 : 6-trimethylmannose were obtained from methylated cherry gum, and free rhamnose from methylated slippery elm mucilage.

Electrophoretic Behaviour of Modified Ovalbumins

IT has been shown recently by Linderstrøm-Lang and Ottesen[1] that ovalbumin is transformed, by the action of a bacterial enzyme from *Bacillus subtilis*, into a protein that crystallizes as rectangular plates from ammonium sulphate. In an earlier paper[2], MacPherson, Moore and Longsworth report that an ovalbumin component, A_2 (characterized by its mobility in the electric field), increased at the expense of another one, A_1, during storage of a salt-free, isoelectric solution under toluene. It therefore seemed of interest to compare the electrophoretic behaviour of the enzyme-modified ovalbumin with the A_2-form of the original protein.

Ovalbumin recrystallized three times[3] was used as starting material. With the aid of a dry powder containing the bacterial enzyme from *Bacillus subtilis*, kindly furnished by Prof. Linderstrøm-Lang, the enzyme experiments were carried out as described by the Danish workers[1]. All the electrophoretic patterns were obtained after electrophoresis of a 1·2 per cent solution of the protein for four hours in a sodium phosphate buffer of *p*H 6·8 and 0·1 ionic strength at a potential gradient of 6·5 volts per cm. Under these conditions, superposition of the patterns permits direct comparison of the relative concentrations of the components and indicates roughly their mobilities. The patterns of the ascending boundaries are presented here because of better resolution. As a result of adjustments occurring at the δ boundary, peaks due to components having similar mobilities will not coincide precisely. The mobilities cited below were therefore computed from the descending patterns.

In Fig. 1 are superimposed the tracings of the patterns of ovalbumin before and after incubation with the bacterial enzyme, and also after recrystallization, as plates, of the enzyme-treated material. In the case of the ovalbumin before and after enzyme treatment, the qualitative appearance of the patterns is similar but the mobilities are different. Although this difference is small, it is sufficient to lead one to expect resolution of the two main components on mixing the enzyme-treated protein and ovalbumin.

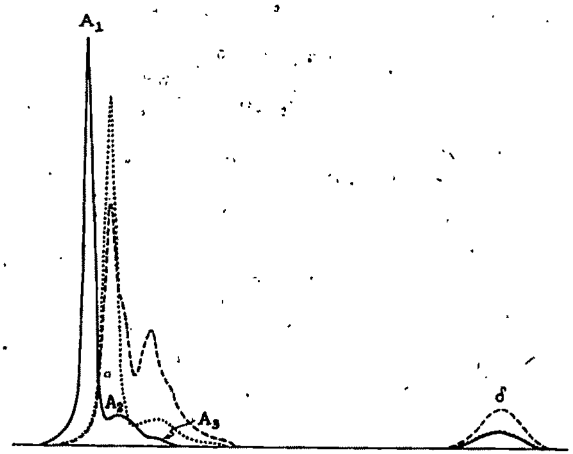

Fig. 1. SUPERIMPOSED TRACINGS OF ELECTROPHORETIC PATTERNS OF: ———, OVALBUMIN; . . . ., ENZYME-TREATED OVALBUMIN; - - - -, THRICE RECRYSTALLIZED ENZYME-TREATED PLATE-ALBUMIN

Attempts to obtain resolution of such a mixture have, however, failed thus far.

If thrice-recrystallized plates are prepared from the mixture of ovalbumin and enzyme, the electrophoretic pattern is that shown by the dashed curve of Fig. 1. It will be noted that the relative concentrations of the components, but not their mobilities, are different from those found for the freshly prepared, uncrystallized plate-albumin. Moreover, this shift in the relative concentrations of the components indicates that plate-albumin as first formed by the action of the enzyme on ovalbumin undergoes further changes with the time and crystallization. It has also been observed that urea at a concentration of 3 per cent accelerates these changes.

In Fig. 2, the full curve again represents freshly prepared ovalbumin, while the dashed curve represents the same preparation after it had been stored at room temperature under toluene as a salt-free solution for four months; the dotted curve is this material after treatment with the enzyme from *Bacillus subtilis*. The mobility, $-4{\cdot}7 \times 10^{-5}$ cm.^{2}/volt sec., of the aged sample agrees closely with that, $-4{\cdot}8 \times 10^{-5}$, of the A_2 component of the fresh ovalbumin. This suggests strongly that the 'aged' ovalbumin (A_2-form) is not the plate-albumin of Linderstrøm-Lang. It is also evident from a comparison of the full and dotted curves of Fig. 1 with the dashed and dotted curves of Fig. 2 that the enzyme acts on the A_2-form in much the same manner as on the original ovalbumin. If the decrease of mobility is due to the splitting-off of low molecular weight fragments carrying charged groups, it thus appears that those lost in the $A_1 \rightarrow A_2$ transformation differ from those affected by the enzyme.

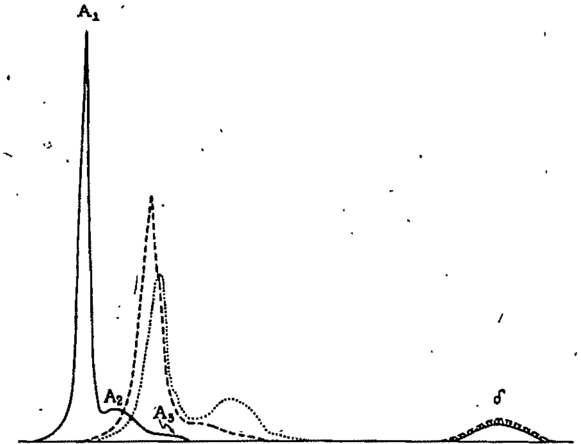

Fig. 2. SUPERIMPOSED TRACINGS OF ELECTROPHORETIC PATTERNS OF: ———, OVALBUMIN; - - - -, 'AGED' OVALBUMIN (A_2); . . . ., ENZYME-TREATED A_2

It should be noted, however, that my A_2-preparation crystallized as plates both before and after enzyme treatment, whereas the original ovalbumin crystallized as needles. During the preparation of the A_2-form, 12 per cent of the total protein was precipitated and the solubility of the remaining product in ammonium sulphate increased considerably[4]. In contrast with the behaviour of plate-albumin, 3 per cent urea has no effect on the electrophoretic patterns of the A_2-form.

At this stage of the work it seems of considerable interest to stress the fact that it is possible to transform, without serious degradation, a protein like ovalbumin into several proteins which differ from each other in at least one property—their behaviour in the electric field. Although no mechanism is suggested for the $A_1 \rightarrow A_2$ transformation, there appears to be no experimental evidence that excludes an enzymatic reaction in this case as well as in the formation of the plate albumin. Such a postulated enzyme could arise either from bacterial contamination or from the egg-white itself.

This problem was started during the tenure of a Commonwealth Fund Fellowship. I wish to thank Dr. D. A. MacInnes for the privilege of working in his laboratory, and express my sincerest thanks to Dr. L. G. Longsworth for help in preparing this note.

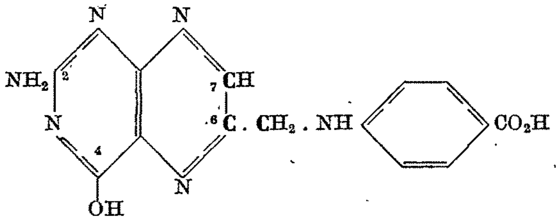
Reductone and the Synthesis of Pteridines

As we have pointed out[1] that the 3-carbon atom unit comprising the ring atoms 6 and 7 and the exocyclic carbon atom (indicated in heavy type) in pteroic acid (I) might be derived from a triose, 3-phosphoglyceraldehyde and phosphodihydroxyacetone being specifically mentioned, the suggestion by O'Meara, McNally and Nelson[2] that the strongly reducing non-sulphydryl substance found in bacterial cultures during the logarithmic phase of growth might be reductone, CHO.C(OH) : CH(OH), seemed to us to have considerable significance in that connexion. O'Meara and his colleagues suggested that p-aminobenzoic acid acts as a stabilizing agent for reductone in bacterial metabolism, enabling the cell to store reductone and to utilize it as required, presumably, from the context, after hydrolysis of the reductone – p-aminobenzoic acid condensation product to free reductone. They also showed that the reductone – p-aminobenzoic acid compound was capable of being utilized by streptococci as a source of energy for growth, and suggested that sulphonamides interfere with bacterial growth by combining with reductone and preventing it from becoming available for the use of the cell.

Another possibility which presents itself is that, in normal bacterial metabolism, *p*-aminobenzoic acid and reductone are first linked together and then incorporated into pteroic acid and the other factors of this group, such as pteroylglutamic acid, whereas, in sulphonamide bacteriostasis, the drug combines with reductone, and the condensation product is incorporated into a biologically inert analogue of pteroic acid.



I

We have examined the possibility of using reductone in the synthesis of pteridines, and it appears desirable to indicate the scope of this work in view of the recent communication by Angier *et al.*[3], who have similarly used reductone, without, however, realizing its possible biogenetic significance. In preliminary experiments[4] using reductone – *p*-aminobenzoic acid and 2 : 4 : 5-triamino-6-hydroxypyrimidine in aqueous solution, we regularly obtained evidence of the formation of the 7-isomer of pteroic acid. The use, however, of reductone – methyl *p*-aminobenzoate and 2 : 4 : 5-triamino-6-hydroxypyrimidine in 95 per cent alcohol has led to the formation of pteroic acid, identified by its ultra-violet absorption spectrum in alkaline solution, which showed maxima at 257, 275 and 365 mμ with E (1%, 1 cm.) 840, 755 and 290 respectively in good agreement with the literature[5,6], and by aerated alkaline hydrolysis to 2-amino-4-hydroxypteridine-6-carboxylic acid and *p*-aminobenzoic acid. Experiments with reductone – sulphanilamide and with reductone – *p*-methylsulphonylaniline have afforded analogous products.

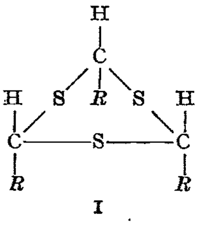
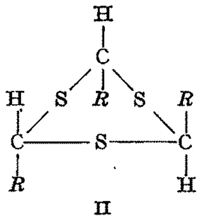
Stereochemistry of Trimeric Thioaldehydes

ACCORDING to Baumann and Fromm[1] the existence of two forms of trimeric thioaldehydes, known as α- and β-forms, is due to stereoisomerism (cf. I and II); these stereoisomers have their substituents in the *cis* and *trans* position with respect to the ring, which may be regarded as planar or nearly planar.



I



II

Some of the trimeric thioaldehydes are readily converted into their isomers; for example, trithioanisaldehyde, m.p. 127°, is changed into its isomer, m.p. 183°, in less than a minute, on treatment of its solution in benzene with a few crystals of iodine at room temperature, and the change of α- into β-trithiobenzaldehyde is almost as rapid. When α-trithiobenzaldehyde is treated with acetylchloride, crystals of the β-form begin to separate before the α-form is completely dissolved. The α-form of trithioacetaldehyde is converted into the β-form at room temperature in the presence of iodine.

Recently[2] it was pointed out that these changes are not in accordance with Baumann and Fromm's theory. In the cyclic series, interconversion of *cis – trans* isomers takes place *readily* only when there is the possibility of tautomerism; but with the compounds in question there is no such possibility. Current theory demands that in molecules such as I and II the ring structures do *not* restrict the freedom of rotation around the single bonds between the atoms of the ring; therefore, in order to support Baumann and Fromm's stereochemical conception, it must be assumed that iodine and acetylchloride can cause rapid reversible depolymerization and thus bring about the observed change of one form into the other.

The latter conclusion has lately been defended by G. M. Bennett[3], who writes: "The catalytic effect of iodine in causing interconversion of the isomeric trithioaldehydes is not surprising. The ring carbon atoms are each attached to two sulphur atoms, and a reversible rupture of a carbon–sulphur bond in these circumstances is reasonable".

No experimental evidence exists for this theory, nor can it be based on analogy. The trimeric thioaldehydes are thioacetals of aldehydes, a group of substances which are known to be remarkably stable even to alkalis and acids[4].

'Boat' and 'chair' ring isomerism. To explain the existence of α- and β-forms of isomeric trithioaldehydes and the ready conversion of the former into the latter, the following theory has been advanced[2]. The three carbon atoms and the three sulphur atoms in these 1 : 3 : 5-trithian molecules do not lie in one plane, but may be regarded as 'boat' and 'chair' substances, the interconversion then being possible *without assuming a reversible rupture of the carbon – sulphur bond.* (This is also the case if the alpha and the beta isomer has an intermediate form between the boat and the chair structure; theoretically they may have any form which fulfils the above condition.) This explanation has been attacked. Bennett writes: (*a*) "Why, if their suggestion is correct, do not two forms of the parent trimethylene trisulphide exist?" (*b*) "The authors' hypothesis requires more than two isomerides of the trithioaldehydes. . . ."

Our theory demands, indeed, a greater number of stereoisomeric trithioaldehydes than have, so far, been isolated; but Bennett seems to have overlooked the fact that in many cases the number of isomers isolated is also smaller[5] than the number expected on the basis of Baumann and Fromm's hypothesis, which he accepts as correct. This does not invalidate our theory or Baumann and Fromm's explanation; it is a fact, frequently encountered in stereochemistry, that the number of isolated isomers is smaller than the theoretical possible number (for example, polyenes, ketoximes).

Again, Bennett writes, "Chattaway and Kellett[6] succeeded in oxidizing the two trithioacetaldehydes to three isomeric monosulphones. This result is exactly that required by the classical view of the isomerism and is strong evidence of its correctness." Previously[2], we have not discussed the stereoisomerism of the sulphones obtainable by the oxidation of the trithioacetaldehydes, because it is possible that these sulphones do not exhibit 'boat' and 'chair' isomerism, *since they are not interconvertible as are the trimeric thioaldehydes*. Therefore, no conclusion can be drawn from the stereochemical structure of the ring systems of the sulphones as to the stereochemical structure of the ring systems of the trithioaldehydes from which the sulphones have been obtained, or vice versa.

[4] Schönberg, "Thioketone, Thioacetale und Athylensulphide" (Enke, Stuttgart, 1933). Tetramethylthiomethane $C(SMe)_4$, a substance in which the carbon atom is attached, not to *two* sulphur atoms as is the case with the trimeric thioaldehydes, but to *four*, is according to Gibson (*Chem. Rev.*, 14, 454; 1934) "quite remarkable" for its inertness.

[5] Campaigne (*Chem. Rev.*, 39, 1; 1946) enumerates ten trimeric thioaldehydes of the aromatic series of which, so far, only one form has been isolated. Moreover, model molecules built up with Fisher – Hirschfelder – Taylor atom models demonstrate that the existence of some of the theoretical possible forms of the trimeric thioaldehydes is highly improbable in consequence of steric hindrance. Bennett has overlooked this point.

[6] *J. Chem. Soc.*, 1352 (1930).

THE validity of Baumann and Fromm's view of this case of isomerism depends on the relative position of the radicals *R* with respect to the *general* plane of the ring. The concept of the puckered ring was introduced later, and it would now be generally assumed that such rings are in fact puckered. Prof. Schönberg contends that the isomerism is due to two forms of puckering rather than the *cis – trans* arrangement of the radicals.

It is unnecessary to discuss his arguments in detail because crucial experimental evidence is now available. Prof. O. Hassell, of the University of Oslo, has directed my attention to his recent publication with H. Viervoll[1], which I had not seen at the time of writing last summer. This paper describes an electron diffraction examination of trithian and of the α- and β-trithioacetaldehydes. The results show definitely that all three substances have similar puckered rings of the 'chair' type, and the authors also conclude that the methyl groups in the two trithioaldehydes are in the *trans*- and *cis*-positions respectively, as deduced by Chattaway and Kellett.

The Sommelet Reaction

IN 1913 Sommelet[1] observed that when the quaternary compound from benzyl chloride and hexamine is heated in water, or in aqueous alcohol, it is converted in good yield to benzaldehyde. This reaction has become general for the preparation of aromatic aldehydes. Sommelet isolated methylamine as a by-product, and suggested that the reaction mechanism is such that the quaternary compound first hydrolyses to methylene-benzylamine, which then isomerizes to benzylidene methylamine; and that the benzaldehyde and methylamine are derived from the hydrolysis of the latter:

$$[C_6H_5.CH_2.C_6H_{12}N_4]^+Cl^- \rightarrow C_6H_5.CH_2.N{=}CH_2 \rightarrow C_6H_5.CH{=}N.CH_3 \rightarrow C_6H_5.CHO + NH_2.CH_3. \quad (1)$$

No further studies of the reaction mechanism appear to have been carried out until 1945, when Graymore and Davies[2] showed that methylene-benzylamine (or a mixture of benzylamine and formaldehyde) gives benzaldehyde in 70 per cent yield on heating in solution with hexamine, thus apparently supporting Sommelet's mechanism. However, the vital role taken by the hexamine in the reaction was not explained.

We have studied this reaction, and our results may be briefly summarized as follows. Contrary to Graymore and Davies' findings, benzaldehyde can be obtained by allowing benzylamine hydrochloride to react with formaldehyde in the absence of hexamine, but only in poor yield (20–25 per cent). The main product is methylbenzylamine. Not methylamine but ammonia is produced in quantities equivalent to the benzaldehyde formed.

The reaction, therefore, contrary to the supposition of Sommelet, does not consist of a double-bond shift, but is an oxidation-reduction process represented by the equation:

$$C_6H_5.CH_2NH_2 + C_6H_5.CH_2.N{=}CH_2 + H_2O = C_6H_5.CHO + NH_3 + C_6H_5.CH_2NH.CH_3, \quad (2)$$

where $C_6H_5.CH{=}NH$ is probably an intermediate.

In the absence of hexamine, only half the benzylamine is available for conversion to benzaldehyde. The yield of aldehyde, however, is still further reduced by the inevitable side-reaction in which some methylene-benzylamine is reduced by formaldehyde (Plöchl-methylation[3]):

$$C_6H_5.CH_2.N{=}CH_2 + HCHO + H_2O = C_6H_5.CH_2NH.CH_3 + HCOOH. \quad (3)$$

Quantitative determinations of the reaction products show the correctness of these equations. Thus, in a typical run with benzylamine hydrochloride (1 mol.) and formaldehyde (1·38 mol.), 56 per cent of the amine reacted according to 2 (giving 28 per cent benzaldehyde), 33 per cent according to (3), and 11 per cent remained unchanged.

When, on the other hand, hexamine is present, its first hydrolysis product (the $CH_2{=}NH$ fragment) behaves as a hydrogen acceptor, being reduced by both benzylamine and formaldehyde:

$$C_6H_5.CH_2.NH_2 + CH_2{=}NH + H_2O = C_6H_5.CHO + NH_3 + CH_3.NH_2. \quad (2a)$$

$$CH_2{=}NH + HCHO + H_2O = CH_3.NH_2 + HCOOH. \quad (3a)$$

Thus, in presence of hexamine, reactions (2) and (2a) are competitive. It is obvious that for high yields of benzaldehyde, the ratio of hexamine to benzylamine should be kept high. By adding benzyl-chloride drop by drop to a hexamine solution, or by using a large excess of the latter, yields of benzaldehyde equal to 85 per cent are readily obtainable.

The Sommelet reaction is thus essentially the reverse of the Leuckart reaction[4]; fatty-aromatic ketones such as acetophenone, and the corresponding amines are interconvertible by these two reactions[2,5]:

$$C_6H_5.CH(NH_2)CH_3 \xrightleftharpoons[\text{HCOOH}]{\text{hexamine}} C_6H_5.COCH_3 + NH_3.$$

In the case of aldehydes, however, the Leuckart reaction does not stop with the primary amine, but gives the tertiary compound.

Details of our work will be given in a forthcoming publication.

Chemistry of Visual Processes

IN a recent article under the above title in *Nature*, Ball, Collins, Morton and Stubbs[1] discuss the relation between 'action spectra' and 'absorption spectra' of photosensitive pigments in the retina. They show that the 'action spectra' must—purely on account of the physical laws of light absorption—be broader when the optical density of the layer of the photosensitive substance is greater[2].

I may perhaps point out that this effect has been used by Hecht, Shlaer and myself[3] in order to obtain an estimate of the absolute value of the percentage of light absorbed by the rhodopsin in the rods of the dark-adapted human eye. In this investigation, the shape of the rod spectral luminosity curve of the retina (plotted in terms of numbers of quanta) was compared to the shapes of calculated curves giving the percentage of light absorbed by layers of rhodopsin having various maximum optical densities. (The latter curves were called 'percentage absorption spectra': they correspond to the 'action spectra' α of Ball *et al.*[1].) An upper value of 20 per cent was thus arrived at for the maximum absorption of the rhodopsin in the living retina. The hypothesis on which such determinations rest is that equal numbers of quanta absorbed produce equal physiological effects in the retina, whatever the wave-length of the light.

In the sensitivity curves obtained by Granit[4] for single fibres of, say, the frog retina, the complications due to selective absorption of light by the eye media are avoided, and it appears that the above comparison method would thus be likely to yield interesting results. In fact, Granit has found, for example, that "the curve for the frog was slightly broader than the visual purple [rhodopsin] absorption curve"[5]. Now the visual purple curve referred to here is a curve obtained *in vitro*, for a layer of solution having, of course, a particular optical density. It is then possible that a curve calculated for a higher density would give an accurate fit with the sensitivity curve of the frog. The particular density value giving such a fit could then be taken as an estimate of the optical density of the rhodopsin layer in this retina. Knowledge of the absolute value of this density is of intrinsic interest, since it makes it possible to calculate the number of quanta absorbed, that is, the number of rhodopsin molecules acted upon in the primary photochemical process, under known conditions of stimulation of the retina.

Variation of the Force Constant with the Ionization Potential and the Polarizability for some Halogen Compounds

VARIOUS attempts have been made to systematize the force constants of chemical linkages. In the formulæ of Badger[1] and of Clark[2] relating the constant k_{A-B} with the interatomic distance r_{A-B}, there occur arbitrary constants the magnitudes of which depend on the positions of the atoms A and B in the Periodic Table, and in the later formula of Gordy[3] the electro-negativities of A and B are involved. None of these relations holds very generally.

I have recently investigated systematics in the force constants of halogen compounds, and evidence has been obtained for the existence of a linear relation between the force constant k_{A-X} and the ionization potential V_i of the variable halogen atom X. The results for the series HX, CX_4, SiX_4, BX_3, PX_3 and CH_3X are shown in Fig. 1. For all except the first of these series the constants are ambiguous, there being several frequencies involving the halogen atoms. In CX_4 and SiX_4, k is obtained from the single totally symmetric Class A_1 mode, for BX_3 from the single totally symmetric Class A_1' mode, and in PX_3 from both $P—X$ stretching modes, using a general potential function[4]; k_{C-X} in the methyl halides is obtained from ν_{C-X} on the assumption that the methyl group remains rigid in this mode.

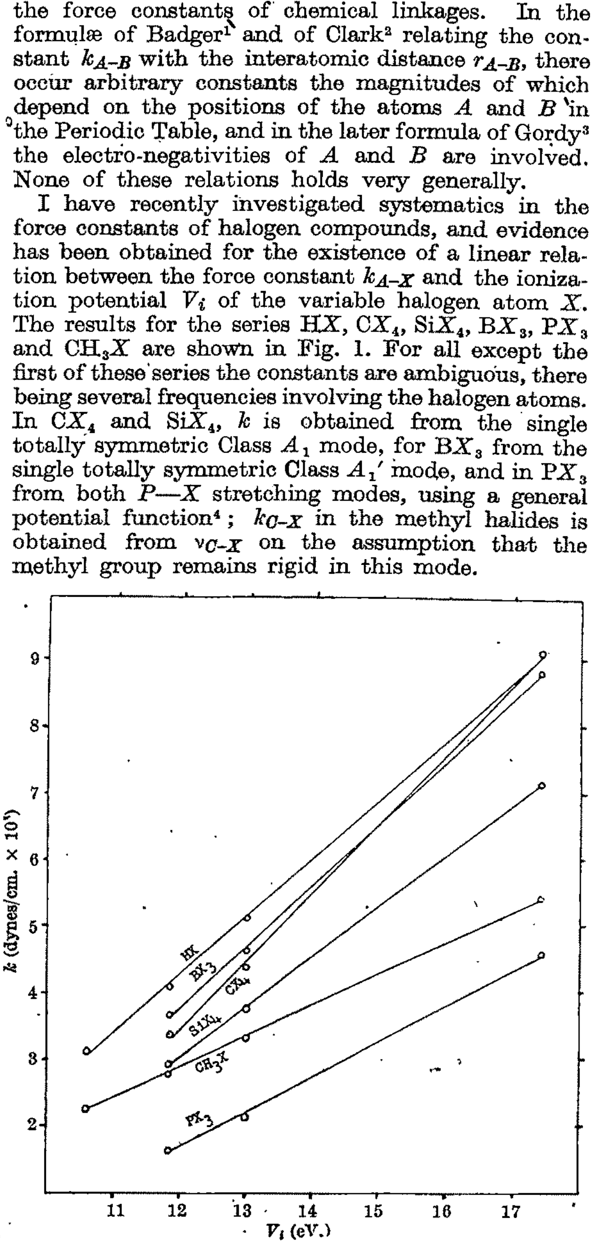

Fig. 1

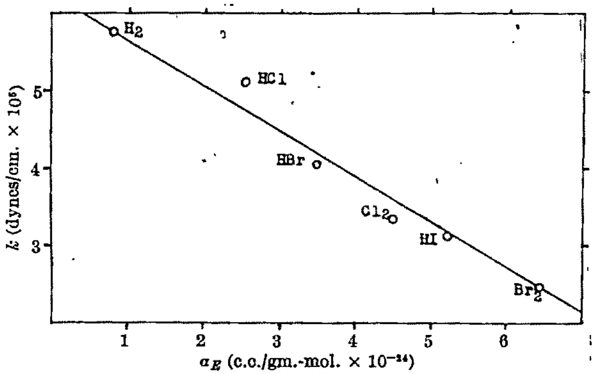

Fig. 2

Even allowing for ambiguities in the force constants, the linear relation between k and V_i is remarkable. The ionization potential is a measure of the tightness of binding of the outer valence electron; the above relation implies that, in a given series, the valence bond is the stronger the greater the force required to transfer the outer electron into the valence orbital. There is also evidence that the slope $(\partial k/\partial V_i)$ is related to the position of the atom A in the Periodic Table; thus it is less for SiX_4 than for CX_4, and, though the data are incomplete, this decrease appears to continue through GeX_4 and SnX_4.

A further relationship which appears worthy of note is that between the force constants of diatomic molecules HX and X_2 and the corresponding electron polarizabilities obtained from dispersion data[5]. This is shown in Fig. 2. The electron polarizability α_E is a measure of the ease of deformation of the outer electron shell of the molecule; as expected, the relation between k and α_E is an inverse one. The linearity may or may not be real.

The Melanin Problem: a Synthesis of 5 : 6-Dihydroxy-indole and its Derivatives

A COMMUNICATION by Robertson *et al.*[1] under this title makes it necessary for us to record that we have been working on almost identical lines.

When piperonal is condensed with nitromethane, and the resulting 2′-nitro-3 : 4-methylenedioxystyrene nitrated in acetic acid, 6 : 2′-dinitro-3 : 4-methylenedioxystyrene is obtained in good yield. The same dinitro-compound can also be obtained directly from 6-nitropiperonal and nitromethane. Reduction of the dinitro-compound then affords 5 : 6-methylenedioxyindole (blue-red colour with cold Ehrlich's reagent). Similarly, 2′-nitro-2′-methyl-3 : 4-methylenedioxystyrene (from piperonal and nitroethane) is nitrated to 6 : 2′-dinitro-2′-methyl-3 : 4-methylenedioxystyrene (also obtained from 6-nitropiperonal and nitroethane), which is reduced to 5 : 6-methylenedioxy-2-methylindole (bright red colour with cold Ehrlich's reagent). Demethyleneation of the above indoles to the corresponding dihydroxy-derivatives can be effected, but in poor yield, with pyridine hydrochloride.

Details of some of this work are complete and are being submitted to the Chemical Society. It was intended to apply the reaction to the synthesis of the 3-methyl- and 2 : 3-dimethyl-derivatives of 5 : 6-dihydroxyindole, starting from 3 : 4-methylenedioxyacetophenone, by an analogous series of reactions. In addition, we were investigating the synthesis of 5 : 6-dihydroxyindole and its derivatives by the method described by Robertson *et al.*, and also by ring closure of suitable acyl derivatives of 6-aminohomocatechol.

In collaboration with Dr. J. L. Stoves, we are also investigating the Fischer synthesis, starting with 3 : 4-di(benzyloxy)phenylhydrazine.

We have found that 5 : 6-dihydroxy-2-methylindole, as well as 5 : 6-dihydroxyindole, gives a melanin by oxidation (air) in an alkaline medium. The significance of this is referred to in an article which will appear shortly in *Chemistry and Industry*.

Bond-Strength of C—Cd in Cadmium Methyl and of C—I in Methyl Iodide

Heat of Hydrolysis of Cadmium Methyl and the C—Cd Bond-Strength. As part of a programme designed to establish the strength of metal-carbon bonds, we have measured the heats of the reactions:

(1) $CdMe_2(liq.) + 2H_2O(liq.) \rightarrow Cd(OH)_2(ppt.) + 2CH_4(g.) + Q_1$.

(2) $CdMe_2(liq.) + H_2SO_4(aq.) \rightarrow CdSO_4(aq.) + 2CH_4(g.) + Q_2$.

The reactions were carried out *in vacuo* in a sealed metal vessel, and the heats of reaction measured in an adiabatic calorimetric system. Analysis of the products of reaction revealed that the reactions proceed as written, with little or no side-reactions.

The mean of several experimental determinations of the hydrolysis heat gave

$$Q_1(-\Delta H) = 48{\cdot}5 \pm 0{\cdot}4 \text{ kcal. mole}^{-1},$$

corresponding to a heat of formation[3] (at 20° C.)

$$Q_f(CdMe_2, \text{liq.}) = -16{\cdot}0_5 \pm 0{\cdot}4 \text{ kcal.}$$

From the heat of reaction with sulphuric acid, we have obtained

$$Q_f = -16{\cdot}3 \pm 0{\cdot}2 \text{ kcal.}$$

This latter value is regarded as the more accurate of the two estimations.

Bamford, Levi and Newitt[1] obtain for the heat of vaporization of cadmium methyl 8·5 kcal., from which we obtain

$Q_f(CdMe_2, g.) = -24{\cdot}8 \pm 0{\cdot}2$ kcal., leading to

$Q_a(CdMe_2, g.) = 314{\cdot}0 + 2L$ kcal., for the heat of formation from normal atoms (L is the heat of sublimation of carbon).

Using $D(CH_3—H) = 102$ kcal. for the dissociation energy of the first C—H bond in CH_4 [2], the above Q_a value gives 66·2 kcal. for the sum of the dissociation energies of the two Cd—C bonds in cadmium methyl. The latter figure is independent of the value assumed for L. The *mean* bond dissociation energy is accordingly 33·1 kcal. We would point out, however, that it cannot be assumed that the bond dissociation energies of the first and second Cd—CH$_3$ bonds are equal to one another.

Heat of Formation of Methyl Iodide, and the C—I Bond-Strength. We have observed that the reaction between cadmium dimethyl and iodine, in dry ether, proceeds almost exclusively according to the equation (1):

$$(1)\quad \mathrm{CdMe_2(liq.)} + 2\mathrm{I_2(ether)} \rightarrow \mathrm{CdI_2(ppt.)} + 2\mathrm{CH_3I\ (ether)}$$

when the dimethyl is added, with stirring, to a solution of excess iodine in ether. The side-reaction (2):

$$(2)\quad \mathrm{CdMe_2} + \mathrm{I_2} \rightarrow \mathrm{CdI_2} + \mathrm{C_2H_6}$$

occurs to an extent of 1–3 per cent under the conditions we have used.

The heat of reaction (1) has been found in an adiabatic vacuum calorimeter to be 75·6 ± 0·5 kcal. Combining this heat value with our value for the heat of formation of CdMe$_2$(liq.), and with published values for the heat of formation of CdI$_2$(ppt.)[4], and the heat of solution of iodine in ether[4], we obtain

$$Q_f(\mathrm{CH_3I,\ liq.}) = 3{\cdot}8_5 \pm 0{\cdot}4\ \mathrm{kcal.},$$

for the heat of formation of liquid methyl iodide at 20° C.

Assuming $D(\mathrm{CH_3—H}) = 102$ kcal.[3], our value for $Q_f(\mathrm{CH_3I})$ leads to

$$D(\mathrm{CH_3—I}) = 55{\cdot}0_5 \pm 0{\cdot}4\ \mathrm{kcal.},$$

for the dissociation-energy of the C—I bond in methyl iodide. This may be compared with the value 54–55 kcal., given by Butler and Polanyi[5], from kinetic studies, and 54·75 ± 1·4 kcal., recently reported by Ubbelohde and Mackle[6], from thermochemical measurements.

A full description of this work will be published elsewhere.

Atomic Oxygen and Dissociation in Flame Gases

IT has been shown that an abnormal dissociation obtains in flame gases resulting from the combustion of carbon monoxide–air mixtures[1,2]. (Such an abnormal dissociation also obtains in hydrocarbon flame gases[3].) If, as we believe, the dissociation products of metastable carbon dioxide molecules are carbon monoxide and atomic oxygen, there must be a considerable concentration of atomic oxygen in the flame gases unless there is a large excess of carbon monoxide present, in which case atomic oxygen recombines almost as soon as it is formed.

Experiments utilizing the Gaydon nitric oxide test for atomic oxygen[4] confirm this. Perfectly mixed mixtures of 30 per cent carbon monoxide + 70 per cent oxygen and 87 per cent carbon monoxide + 13 per cent oxygen contained in a tank were burnt in a Smithells separator and nitric oxide injected (through a fine quartz tube) into the flame gases at various points *above* the combustion zone. In the case of the excess oxygen flame gases there was a marked yellow-green coloration indicating atomic oxygen; but in the case of the excess carbon monoxide gases there was only a very faint brown coloration.

With the exceptionally fine plain and quartz-covered wires we use, there is no detectable difference between the temperatures measured by these wires when they are immersed in flame gases resulting from the combustion of very over-rich mixtures. But in the case of excess oxygen flame gases the temperatures measured by the wires differ by as much as 300° C. or 400° C.[1,2]. The concentration of carbon monoxide and atomic oxygen would thus appear to be very considerable in the latter flame gases.

The nitric oxide experiments have been repeated with the mixtures 10 per cent methane + 90 per cent oxygen and 80 per cent methane + 20 per cent oxygen. The results were similar to those with the carbon monoxide mixtures. Experiments with fine plain and quartz-covered platinum wires in methane and propane flame gases yield results which are also similar to those for carbon monoxide flame gases. The difference between the wire temperatures for the excess oxygen flame gases is, however, rather less; it varies between 200° C. and 300° C.[3].

In the experiments referred to above the mixtures were burnt at atmospheric pressure, and what for all practical purposes may be regarded as a state of equilibrium is very rapidly attained after the initiation of combustion; in other words, the reaction zone is very narrow. When inflammable mixtures are burnt at low pressures the reaction zone becomes greatly extended, and the flame gases in this zone possess a great apparent potency. For example, when a perfectly mixed mixture consisting of 90 per cent carbon monoxide + 10 per cent oxygen is burnt under certain conditions at a pressure of 0·15 atmosphere, a fine platinum–rhodium wire (melting point 1,850° C.) is rapidly melted in the zone, although the theoretical flame gas temperature calculated by means of thermochemical data is only 1,690° C.

It would seem that these extensive reaction zones offer good opportunities for investigating intermediate products; but we would especially stress that it is essential to arrange for the perfect mixing of the inflammable gases before combustion.

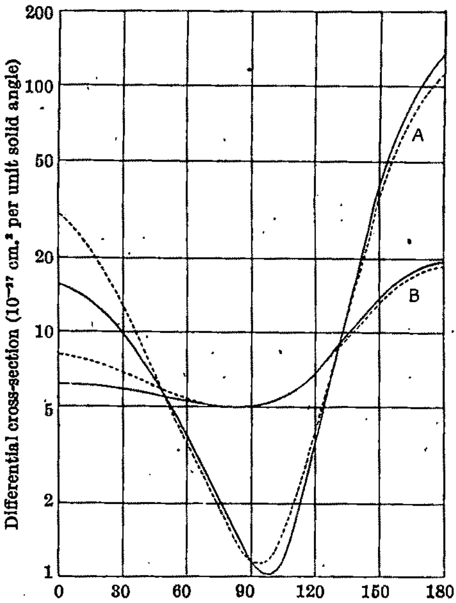
Scattering of 100-MeV. Neutrons by Protons

CALCULATIONS of the differential cross-section for the scattering of 100-MeV. neutrons by protons have been made, using an exponential-well potential $V_0\, e^{-r/a}$ with two values of the range a. The depths of the triplet and singlet interactions, determined from the deuteron binding energy and the cross-section for the scattering of slow neutrons by protons, were respectively 313·5, 191·2 MeV. for $a = 0{\cdot}5 \times 10^{-13}$ cm., and 98·4, 60·0 MeV. for $a = 1{\cdot}0 \times 10^{-13}$ cm. The two cases of exchange forces and of symmetric forces were assumed.



A : $a = 1 \cdot 0 \times 10^{-13}$ cm. B : $a = 0 \cdot 5 \times 10^{-13}$ cm. Full lines, exchange forces ; broken lines, symmetric forces

ANGULAR DISTRIBUTION OF SCATTERING OF 100 MEV. NEUTRONS BY PROTONS

A new method[1] for determining the phase shifts of the partial waves enabled the contribution to the phase of the potential within a distance of $4a$ from the origin to be rapidly obtained, the correction for the remainder of the potential coming from a perturbation calculation. For the two ranges, phases beyond $l = 4$, 8 respectively could be neglected.

The differential cross-sections for the two cases are shown on a logarithmic scale in the accompanying diagram. It is seen that even for the energy considered, the type of force has little effect on the shape of the differential cross-section, or on the total cross-section, which is of the order $0 \cdot 09$, $0 \cdot 13 \times 10^{-24}$ cm.^{2} for the two ranges respectively. These results are similar to those published recently[2] for a lower range of energies and a square-well potential.

Comparison of Cross-sections for the Capture of 220 and 900 keV. Neutrons

WE have compared the capture cross-sections of a number of nuclei, for neutrons of 220 and 900 keV. The neutrons were produced by placing 400 mc. of radiothorium (contained in a platinum cylinder 5·5 mm. high and 5·5 mm. in diameter) inside either a beryllium cylinder (height 2·3 cm., wall thickness 9 mm.) or a cylindrical brass vessel containing heavy water (height 15 mm., wall thickness of D_2O 5·75 mm.). The photo-neutrons obtained thus are fairly monokinetic; but owing to the conservation of momentum they are spread out over an energy interval of 57 keV. in the case of heavy hydrogen and 25 keV. in the case of beryllium. (G. D. Latyshev[1] published new measurements of the thorium (C C″) gamma-rays which show that besides the main line at 2·62 MeV. there exists a line at 2·2 MeV. the relative intensity of which is 5 per cent as compared to the main line. This line gives rise in the case of heavy hydrogen to neutrons of only 10 or 20 kV.; but an estimate of the cross-section of the photo-effect on that region shows that the total number of these slow photo-neutrons will not be more than 1·5 per cent of those of 220 kV. energy.)

Considerable care has to be taken to avoid slowing down of the photo-neutrons due to the moderating influence of the surrounding materials. The samples were irradiated inside an asbestos hut on the laboratory roof. It was found that irradiation inside the hut produced the same amount of artificial radioactivity as irradiation outside. Under these conditions, slowing down can still occur in the heavy water or beryllium itself. It was found, however, by reducing the amount of heavy water to one quarter of the quantity used in the main series of measurements, that this effect is negligible under our conditions, except in the case of indium, where a correction of 12 per cent had to be applied.

The samples for irradiation were, so far as possible, used in the form of foils bent to a cylinder 2·8 cm. high and 2·8 cm. in diameter, in the middle of which the source of photo-neutrons was placed for irradiation. Powders were filled into a double-walled cylinder of brass placed around the neutron sources.

The ratios of cross-sections were obtained by irradiating the same sample of each element in turn with each of the two photo-neutron sources. The relative number of neutrons produced by the two sources was determined separately[2]. The ratio of the intensity of artificial radioactivity obtained in the two irradiations, with a small correction, leads thus to the ratio of the cross-sections. The correction of 6·5 per cent was applied to allow for the anisotropy of neutron emission from the heavy water; it was obtained empirically.

Active isotope	^{28}Al	^{56}Mn	^{64}Cu	^{66}Cu
Ratio of cross-sections	1·7±0·5	2·3±0·6	1·0±0·2	1·3±0·5
Active isotope	^{76}As	^{80}Br. 18 min.	^{80}Br. 4·4 hr.	^{82}Br.
Ratio of cross-sections	3·7±0·4	2·0±0·4	1·8±0·3	2·2±0·4
Active isotope	^{104}Rh 94 sec.	^{104}Rh 4·2 min.	^{104,109}Pd	^{111}Pd
Ratio of cross-sections	3·1±0·8	2·2±0·8	2·0±0·3	1·1±0·3
Active isotope	^{108}Ag	^{110}Ag	^{116}In 54 min.	^{122}Sb
Ratio of cross-sections	2·0±0·3	1·00±0·2	0·8±0·1	1·2±0·1
Active isotope	^{128}I	^{139}Ba	^{131}Te	^{165}Dy
Ratio of cross-sections	1·7±0·3	1·9±0·7	1·3±0·4	1·0±0·15
Active isotope	^{187}W	^{199}Pt	^{198}Au	
Ratio of cross-sections	1·3±0·3	2·5±0·6	1·0±0·1	

The ratios of cross-sections are given in the accompanying table, from which it is seen that σ 220/σ 900 varies only between 1 and 4.

These results can be compared with the theory of Fishbach, Peaslee and Weisskopf[3]; the values for σ 220/σ 900 predicted by these authors vary still less than our results. In particular, their theory does not predict ratios of the order of 1 as we observe them in several cases.

We wish to thank Dr. Placzek and Prof. Peierls and Weisskopf for valuable discussions.

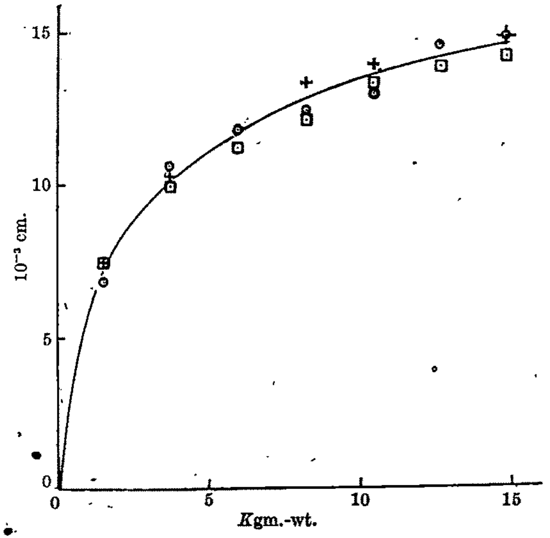
Rate of Wear in the Region of the Validity of Amontons' Law

AMONTONS' law[1] of the direct proportion between the frictional force and the applied normal load has been shown to be valid when the actual area of contact is a small proportion of the nominal area of contact. Recently[2], experimental results obtained under conditions of 'extreme pressure' (in lubrication literature bearing-pressures of at least 15,000 kgm.-wt./cm.^{2} are termed 'extreme pressures') were presented to indicate that, within the region of the validity of Amontons' law, lubricants which reduced the thermo-electromotive forces[3] generated at the area of actual contact also reduced the final wear diameter produced by a revolving steel ball loaded against a metal plate.



RADIUS r (IN 10^{-3} CM.) OF THE FINAL WEAR PRINTS PLOTTED AS A FUNCTION OF THE NORMAL LOAD (IN KGM.-WT.) FOR ONE-MINUTE RUNS WITH LUBRICANTS $A(+)$, $B(\boxdot)$ AND $C(\odot)$, IN THE REGION OF THE VALIDITY OF AMONTONS' LAW

With a four-ball apparatus[4], measurements were made on one hand of the temperature rise of the oil cup (containing the three rigidly clamped steel balls), and on the other hand of the frictional torque, both as a function of the normal load. Depending upon the quality of the lubricant, Amontons' law may remain valid over an appreciable region of normal loads (see table). Within this region, the accompanying diagram represents the dependence of the radius of the final wear print of one-minute runs upon the normal load.

From the geometry of the friction elements, the abraded volume V is

$$\frac{2\pi}{3}a^3\left(1-\sqrt{1-\left(\frac{r}{a}\right)^2}\right)-\frac{a\pi r^2}{3}\sqrt{1-\left(\frac{r}{a}\right)^2},$$

where a is radius of steel balls and r is radius of wear print. To a first approximation $V = \pi r^4/6a$, with a rate of wear for the one-minute run of $3{\cdot}4 \times 10^{-9}$ cm.^{3} per kgm.-wt.

FRICTIONAL TORQUE MEASUREMENTS

Normal load L in kgm.-wt.	Frictional torque F in kgm.-wt. Lubricant A	Lubricant B	$\mu = F/L$ A	B
1·428	0·4496	0·325	0·31	$0{\cdot}2_8$
3·652	1·013	1·174	$0{\cdot}2_8$	0·32
5·878	1·380	1·432	0·23	0·24
5·878	1·837	—	0·31	—
8·10	2·132	2·267	0·26	0·28
10·33	2·978	2·96	$0{\cdot}2_9$	$0{\cdot}2_9$
12·55	3·341	3·437	$0{\cdot}2_7$	0·27
		Mean :	0·28±0·04	0·27±0·04

For a thrust of 80 lb.-wt. (normal load 14,830 gm.-wt.) the temperature rise of the metal cup was about 2° C. as the result of a one-minute run with a straight mineral oil, indicating, on account of the water equivalent of the cup, frictional work of $3{\cdot}57 \times 10^9$ ergs. On the other hand, from the observed frictional torque of about 4,000 gm.-wt., one would calculate for the total work done in one minute 10^{10} ergs. From the observed final wear diameters, $18{\cdot}9 \times 10^{-7}$ gm. of material was calculated to have been abraded from the three clamped steel balls in the one-minute run. Since the latent heat of vaporization of steel (89,025 cal./gm.[5] at 1,000° C.) is the upper limit of the energy required for its abrasion, one can estimate that about 9×10^6 ergs (allowing 2×10^6 ergs for abrasion of the revolving steel ball) have been expended on abrading metal. The 'bearing pressure' at the end of this run was about 21,000 kgm.-wt./cm.^{2}.

In agreement with Whittaker's[6] observation, in the region of the validity of Amontons' law, the work done on abrading matter from the clamped steel balls was in the present case a small proportion (about 10^{-3}) of the total frictional work, the main portion apparently being used for shearing the boundary layer.

Optical Transmission of a Colloidal Solution in a Magnetic Field

THE change in optical transmission of a colloidal solution as a function of the applied magnetic field strength has been investigated both theoretically and experimentally.

In the colloid which has been considered theoretically, the particles are of uniform size and of laminar shape, diamagnetic and magnetically anisotropic. Such particles tend to orientate themselves with the axis of greatest diamagnetic susceptibility normal to the direction of the applied field; the Brownian movement tends to orientate them at random, so that the alignment becomes more complete as the magnetic field strength is increased.

If the dispersion medium is transparent, the particles opaque and the concentration small, classical absorption may be regarded as the predominating factor ; that is, the light absorbed may be assumed proportional to the projected area of the particle. It is then found that the change in optical transmission for light parallel or normal to the magnetic field is a function of H^2/T, H being the magnetic field strength and T the absolute temperature.

Stuart[1] tried to find a suitable method of detecting and measuring small quantities of graphite in oil. He observed that a solution of colloidal graphite shows a change in transmission of visible light when a magnetic field is applied, and that this change varies with the concentration.

Experiments have now been carried out to determine quantitatively the dependence of this effect on field strength ($H \leqslant 4{,}000$ oersteds) and concentration, and the results have been compared with those derived from the theory outlined above; they agree well when the particle size is assumed to be approximately 1 μ. This is nearly the same as the known value of the mean size of the particles in 'Aquadag S' which was used here (information kindly supplied by Acheson Colloids, Ltd.).

The mean particle size has since been found by another method: from Einstein's theory[2] of the Brownian movement, an expression can be derived for the relaxation time, that is, the time required to re-establish random orientation when the field is removed. The relaxation time has been measured with a cathode ray oscillograph and is of order 1 sec., from which again an average particle size of 1 μ follows.

It has already been observed by Stuart[1] that the increase in transmission with a magnetic field parallel to the beam also occurs when an alternating field is applied; this is because the change in transmission is a function of H^2. It seems as if this may have some application in the measurement of rapidly alternating fields.

A full account of this investigation will be published by one of us (F. D. S.) in the near future.

Dielectric Constant of Diamond

The dielectric constant of diamond has been the subject of investigation by a number of workers, among whom particular mention may be made of Robertson, Fox and Martin[1], Whitehead and Hackett[2] and Groves and Martin[3]. The exact value of this constant and whether there is any difference between the values exhibited by the two types, namely, ultra-violet opaque and ultra-violet transparent, appear to be the two main issues involved. The most accurate determination of Whitehead and Hackett gave 5·66 at 800 c./sec. and 27·8° C., whereas Martin and Groves obtained 5·26 by one method and 5·35 by another. Probable reasons for the lower values obtained by Martin and Groves were suggested by them. A significant statement of Robertson and co-workers is that they found no measurable differences for the two types of diamonds.

A special liquid-mixture method useful for the determination of dielectric constants of crystal plates has been developed in this laboratory[4]. In view of the importance of this subject, a determination of the dielectric constant of both types of diamond was undertaken. A type I diamond of oval shape, about 2 sq. cm. in area and 1·42 mm. thick, and a type II diamond of rectangular shape, about 1 sq. cm. in area and 1·27 mm. thick, both kindly lent to us by Sir C. V. Raman, were employed in the investigation. The dielectric constants found were 5·70 and 5·65 respectively for these two plates at a frequency of 1·6 mc./sec. and 26° C. In agreement with Robertson and co-workers, we conclude that there is no measurable difference between the dielectric constants of the two types of diamonds, but the exact value obtained by us is definitely higher than that reported by these authors. The mean of our results, namely, 5·68, is quite close to that obtained by Whitehead and Hackett, and is nearly identical with the extrapolated value of the square of the refractive index, which is found to be 5·67.

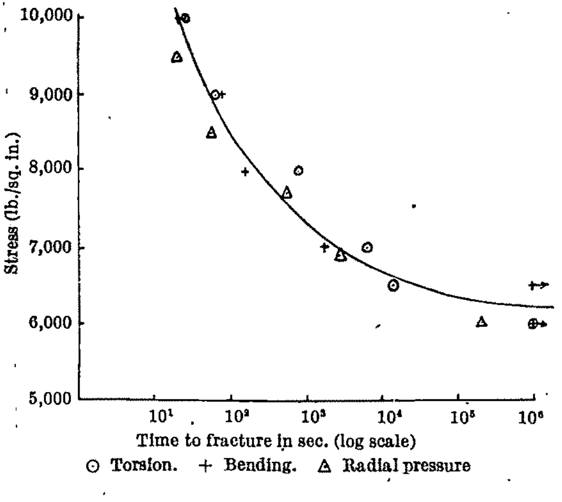
Delayed Fracture of Glass under Tension, Torsion and Radial Pressure

A plausible explanation[1] of delayed fracture of glass is that cracks initially present in the unstressed material gradually extend when glass is loaded. As the cracks extend, the stress at the ends of the cracks increases, until it becomes equal to the maximum stress which the glass can even momentarily withstand; catastrophic fracture then occurs. Other factors being constant, the rate of crack spreading would be expected to depend on the stress at the end of the largest and most unfavourably orientated crack. Delayed fracture in tension and torsion would therefore be expected to occur in equal times, when the glass is subjected to equal principal tensile stresses.

A simple deduction from the crack hypothesis leads to the conclusion that tensile stresses occur at the ends of cracks in rods subjected to radial fluid pressure (no axial force). The magnitude of these



stresses is effectively equal to that occurring in rods subjected to nominally uniform axial tension numerically equal to the fluid pressure. Experiments[2] on glasses with three different compositions broken at constant rate of loading support this deduction.

Briefly, the argument is as follows. A state of radial pressure on a cylindrical rod may be regarded as a state of hydrostatic pressure, on which is superimposed an axial tensile stress numerically equal to the pressure. Under a state of hydrostatic pressure, there is no concentration of stress at the ends of surface cracks; while under an axial tensile stress there is a stress concentration of the order of one hundred. The stress at the ends of cracks in rods subjected to radial fluid pressure is therefore sensibly equal to that at the ends of cracks in rods subjected to an axial tensile stress, numerically equal to the fluid pressure.

Delayed fracture under radial pressure and under axial tension would therefore be expected to occur in equal time when the pressure was equal to the nominal tension stress.

To test these conclusions, delayed fracture experiments in bending, torsion and radial pressure have been made on ¼-in. diameter annealed soda glass rods. The experimental work was done by Mr. S. Pearson. In the accompanying figure, the ordinates represent the nominal principal tensile stresses to which the rods were subjected in bending and torsion, and the radial pressures to which the rods were subjected. The abscissæ represent the logarithm of the corresponding times to fracture. Each point plotted is the median point for twelve nominally identical experiments. It will be seen that the points are all scattered about the same curve. The results are therefore in agreement with deductions from the crack theory.

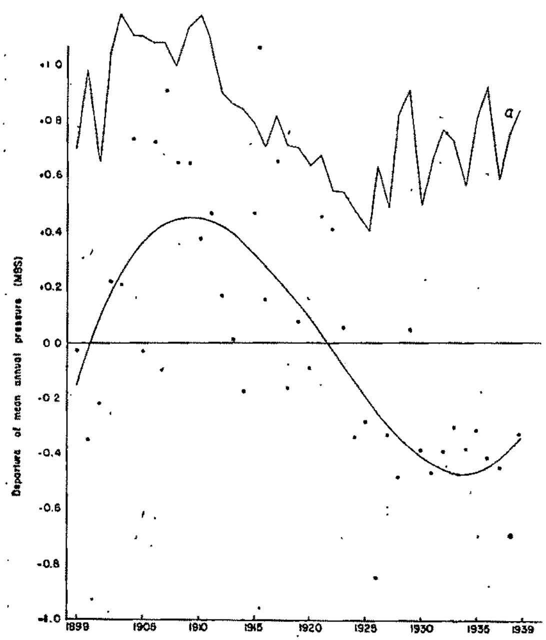
Northern Hemisphere Surface Pressure and Climatic Fluctuations and Vegetation Growth in Northern Finland

THE recent article by Dr. I. Hustich[1] and the accompanying note of Dr. E. W. Jones presenting data on vegetation growth and temperature trends in Europe are of considerable interest when viewed in relation to trends in the surface pressure of the northern hemisphere during the period 1899–1939. I have pointed out recently[2] that there has been a considerable decrease in the total mass of air over the northern hemisphere between 1899 and 1939. The accompanying graph, which is reproduced from that paper[2], shows the departures of mean annual hemisphere pressure from normal for the 41-year period. These values were obtained from the series of Daily Historical Maps[3] prepared in the United States in 1943–44. The smooth curve shown is the cubic regression line fitted to the annual departures by the method of orthogonal polynomials[4].

This curve is practically the reversal of the Curve *a* of the article by Dr. Hustich[1], which has been reproduced at the top of the diagram with the ordinate inverted. In fact, the correlation coefficient between the data shown in Fig. 1 and the series of figures read from Curve *a* given by Hustich is −0·55, a value beyond the 1 per cent significance level. This indicates, therefore, that during the period 1899–1939 there was a tendency for maximum tree-growth in the north of Finland to take place during years of low average pressure over the northern hemisphere.



An explanation that immediately suggests itself is that years with high mean pressure tend to be years with lower mean temperature in northern latitudes, since high pressure in the northern latitudes is usually associated with cold polar anticyclones. Furthermore, it has been pointed out[2] that the cyclical variations in pressure above lat. 60° N. are similar to that shown in the accompanying graph but much more pronounced in amplitude. This hypothesis appears to be reasonable since the correlation coefficient between the mean annual hemisphere pressure and the mean annual temperature of stations above lat. 60° N. was found to be negative for each of six stations that were examined. The largest coefficient numerically was −0·55 for Bodo, Norway, and the smallest coefficient was −0·17 for Vardo, Norway.

Hustich points out the fact that summer temperatures in northern Finland increased during the period 1890–1939, and the influence of precipitation on growth in the far north is of minor significance. The correlation between the tree-growth data shown by Hustich and the mean summer temperature determined by taking the average of Karasjok, Karesaundo and Vardo, Norway, is found to be 0·47, slightly less than the correlation between tree-growth and mean annual hemisphere pressure. The multiple correlation coefficient between tree-growth and these two factors is 0·68, which indicates that nearly half the variation in annual tree-growth is accounted for by the regression on local summer temperature and the mean annual pressure for the hemisphere. Since the mean annual pressure for the hemisphere is only one crude index of the general circulation of the atmosphere that prevailed during the year, it seems quite remarkable for it to account for such a large proportion of the variation in tree-growth. No doubt there are other indices or parameters characterizing the general circulation pattern that should do as well or better.

In conclusion, it seems appropriate to endorse the closing remarks of Jones[1] to the effect that the investigation of trends of growth shown by trees over long periods offers a promising field of work for the climatologist studying long-period fluctuations in the world's climate.

Dissociation Energies

In my recent book[1] there are a few errors and misprints. As it may be a year or two before a second edition is in print and use of the data might lead to errors in other people's work, it seems desirable to record them. I am indebted to Dr. L. Brewer for pointing out these errors. Those for HBr and HI also occur in Herzberg's book[2].

	Dissociation energy			
	Value given		Correct value	
Molecule	e.v.	k.cal./mole	e.v.	k.cal./mole
F_2	2·2 ± 0·6	72	2·2 ± 0·6	50
HBr	3·60	83·0	3·78	87·4
HBr^+	3·3	76	3·5	80
HI	2·75	63·4	3·1	71·6
HI^+	3·24	75	3·6	83

The Swimming of Dolphins

In reply to Mr. A. H. Woodcock's[1] inquiry whether other observers have seen the 'motionless' swimming of dolphins and what explanations may have been given, I can state that I have seen this phenomenon on several occasions.

One particular instance about which I have notes available occurred on January 6, 1926, in approximately lat. 55° 15′ S., long. 39° 05′ W. At midday seven dolphins, almost certainly of the species *Lagenorhynchus cruciger*, played for some time round the bows of the whaler *Don Ernesto*, making between 9 and 10 knots, course S.W. 1/2 S., weather clear, several tabular bergs in sight. I photographed the dolphins from the bow rollers directly above the animals as they swam immediately ahead of the forefoot, slipping through the water with no apparent swimming motion. The beauty of this seemingly effortless speed impressed me greatly.

Mr. Woodcock's explanation that 'motionless' dolphins may be riding the bow wave and falling down the inclined surface did not occur to me. I have always assumed that the forward movement of 'motionless' dolphins must be due to rapid up and down strokes of very small amplitude by the tail flukes, strokes which escape notice because the disturbed surface of the water hinders exact observation. This assumption now appears to be incorrect in view of Mr. Woodcock's observation of a 'motionless' dolphin swimming on its side for a distance of 304 metres with no visible oscillation of the tail.

References in Scientific Literature

There is now increasing use, in scientific literature, of a system in which all references to literature are inserted in the text in the same type. I quote two recent ones: (*a*) from British literature and (*b*) from the United States.

(*a*) "The first step in the breakdown of glycogen is the formation of glucose-1-phosphate and, as shown by Cori and his coworkers (Cori, Cori & Hegnauer, 1937; Cori, Colowick & Cori, 1937; Cori, Cori & Schmidt 1939; Cori, Schmidt & Cori, 1939; Cori & Cori, 1939; Cori, Green & Cori, 1942), this reaction is reversible." . . . "Glycogen has been produced *in vitro* with minced tissues (Kiessling, 1936, 1937; Ostern, Herbert & Holmes, 1939; Ostern & Holmes, 1939), tissue extracts (Cori, Cori & Schmidt, 1939; Cori & Cori, 1939; Mirski & Wertheimer, 1942) and with purified or even crystalline enzymes (Cori *et al.*, 1937; Cori, Colowick & Cori, 1938; Cori *et al.*, 1942; Kiessling, 1939 a, 1939 b; Colowick & Sutherland, 1942; Schäffner & Specht, 1938, 1939)."

(*b*) "Impairment of the ability of the thyroid to collect or retain radioactive iodine has been reported with thiourea (Keston, Goldsmith *et al.*, 1944; Buciero and Vieira, 1944; Chagas, De Robertis, and Couceiro, 1945), thiouracil (Rawson, Tannheimer and Peacock, 1944; Rawson, Cortell *et al.*, 1944; Rawson, Evans *et al.*, 1944; Couceiro, Vicira and de Moraes, 1944; Salter, Cortell, and McKay, 1945) and promizole (Higgins and Ingle, 1946)."

Surely we are losing sight of the object of the printed paper, namely, that it should be readable. Nowadays it may be somewhat of an athletic feat to pick out the text. It is time that the whole question of references was reconsidered and that the convenience of the printer was not made the main consideration. Even smaller type for the references would be an improvement, or some system which made introductory words stand out.

In this respect contrast the readability of (*c*) from another British journal.

(*c*) "the earlier statement that all known heteronuclear mononitronaphthylamines were orange-red required modification in that the 5- and 6-nitro-2-naphthylamines should be styled orange-yellow and golden-yellow respectively[2,5–8]. (Since this work was completed, Hertel[9] reports that . . .)"

(2, 5–8 and 9 are placed in a convenient footnote.)

BRITISH SCIENTIFIC INSTRUMENTS

THE 1948 Exhibition of Scientific Instruments, the thirty-second of the series, held by the Physical Society at the Imperial College of Science and Technology, London, was worthy of its predecessors. As in 1947, the Exhibition was open for four days, April 6–9 inclusive, during the University Easter vacation. In order to limit the attendance to reasonable proportions, it was necessary again to issue tickets for admission on all the days. There was therefore no 'public' or 'open' days as in pre-war Exhibitions. Nevertheless, the number of visitors (including fellows of the Physical Society) attending the Exhibition this year reached a total of approximately 13,000. Certain sessions were rather overcrowded; but on the whole the restriction on the issue of tickets had the desired effect and visitors could view the exhibits in reasonable comfort.

It had been arranged that the Right Hon. J. H. Wilson, President of the Board of Trade, should open the Exhibition on April 6; this coincided with the presentation of the Budget in the House of Commons, and the planned opening had to be cancelled. Prof. G. I. Finch, president of the Physical Society, however, acted as deputy to the President of the Board of Trade in opening the Exhibition. It will be recalled that the opening function was performed in 1946 by Sir Stafford Cripps. The national importance of this Exhibition is demonstrated not only by the high standing of the Cabinet Ministers invited to open it, but also by the high quality and export value of the scientific instruments which are exhibited. As a display of such instruments the Exhibition is pre-eminent in Great Britain.

In its youth, the Exhibition was primarily concerned with 'research' items, but at a later stage in its development a certain number of trade exhibits of a novel character were also included. Now the Exhibition is primarily 'trade', while the 'research' section is relatively small in size but large in interest. This year, the number of firms represented in the trade section was 124, while in the Research and Educational Section there were 38 exhibitors. It should be pointed out, of course, that a number of firms and organisations represented in the Trade Section exhibit also in the Research Section. Special mention should be made on this occasion of the exhibition of the film "Atomic Physics" once during each session of the Exhibition. The film displays very vividly and with good historical accuracy the growth of atomic physics since the time of Dalton's atomic theory; and is a noteworthy scientific achievement for which much credit is due to those who conceived and produced it (see also *Nature*, Dec. 13, 1947, p. 822).

On each of the first three evenings of the Exhibition a discourse was given dealing with recent developments in a particular branch of physics and its applications.

The discourse by Dr. K. Mendelssohn of the Clarendon Laboratory, Oxford, dealt with the subject of "Low-Temperature Physics". In the course of his talk Dr. Mendelssohn explained that the fundamental relation between temperature and disorder provides a basis for an understanding of both the technique and the aims of low-temperature research. In order to lower the temperature we must have at our disposal a system the entropy of which changes appreciably with a variable other than the temperature. Such a system is a gas or a paramagnetic salt, the variables being the pressure and the magnetic field respectively. The techniques of gas liquefaction and adiabatic demagnetization were described. The increase of order with decreasing temperature provides two striking phenomena, superconductivity and the superfluidity of liquid helium. Experiments show that the electrons in a persistent current as well as the helium engaged in superflow have zero entropy.

In his discourse on "The Reflecting Microscope", Dr. C. R. Burch, of the University of Bristol, surveyed some of the fields in which the instrument seemed likely to play a prominent part; for example, in micro-dissection and ultra-violet absorption studies made possible by the long working distance and focal achromatism. He showed slides illustrating the new ground being broken in ultra-violet cytological spectromicrography by Dr. R. Barer (of the Department of Human Anatomy, Oxford). In his discourse Dr. Burch was assisted by Mr. K. W. Keohane and Mr. W. J. Bates, both of the University of Bristol. The former showed photomicrographs of red-hot metals, and the latter described the use of the reflecting microscope in the study of cosmic ray phenomena in nuclear photographic emulsions, using phase-contrast illumination.

Mr. H. L. Kirke, director of research in the British Broadcasting Corporation, selected for the title of his discourse "Studio Acoustics". He described room acoustics as 'the scenery of sound' and then discussed briefly the history of the subject from the time of Sabine's early work. The effect of reverberation time and its relationship to the size of the room and number of performers was considered. He showed slides of the reverberation frequency characteristic of a number of halls and studios, pointing out the defects of certain studios. The old method of measurement of reverberation time using a warble tone was described, together with the effect of eigentone modes and other resonances. He referred also to the methods of measuring absorption in the various frequency ranges, with particular reference to absorption in the low-frequency range of vibrating panels and resonators. Demonstrations were given by recordings and lantern slides of some of the peculiar effects of resonances, concluding with references to the effect of shape of wall surfaces on reflected sound, particularly with polycylindrical surfaces.

An interesting film, "Physics of the Film", was shown at intervals by the British Kinematograph Society, illustrating the faults in picture and sound due to neglect of fundamental physical and mechanical principles. The application of photographic theory to the colour film was especially illustrated.

It is not possible in a review such as this to make even a brief reference to more than a few of the multitude of interesting exhibits. The reader is recommended to consult the Exhibition catalogue, a well-illustrated volume of about 370 pages, for further particulars. This catalogue, available on application to the Secretary of the Physical Society, is a valuable book of reference, renewed annually, to the scientific instrument industry in Great Britain.

A centre of attraction to visitors in the Research Section was the demonstration of the production and properties of 8 mm. electromagnetic waves. The advent of power sources of this wave-length makes possible the demonstration of many optical phenomena such as interference, diffraction, polarization, lenses, 'blooming', etc. A novel feature of this exhibit was the use of a neon tube containing a large-diameter plane metal plate containing a large number of 'slit' dipoles. This surface served as the optical screen to make 8 mm. waves 'visible'. In another research exhibit a cathode ray tube was used to display three-dimensional data. The Post Office Engineering Department demonstrated the use of radar technique in the location of line faults. When the radar pulse arrives at a fault or other discontinuity, it is reflected back—just as a radar pulse is reflected from an aeroplane—and the echo arrives at the sending end after a time interval which is a measure of the distance of the fault, the time interval being indicated in the usual manner on a cathode ray screen.

An exhibit which will no doubt be of interest to smokers in these days of expensive tobacco provided an indicator of the moisture content of a small sample of tobacco. The sample exhibited contained 40 per cent moisture!

In a study of underwater noise produced by ships' propellers, a method was demonstrated of measuring the distribution of pressure across the face of a propeller blade while it is revolving in water. In another application of acoustics; supersonic vibrations were used as a depth gauge. This gauge is a development of the supersonic flaw detector, using echo technique with cathode ray tube indication.

On the optical side may be mentioned a fine array of microscopes, demonstration of phase-contrast methods and electron microscopes. Developments in phosphors were illustrated in a demountable cathode ray tube. Some unusual tungstate phosphors activated by uranium or bismuth showed the interesting characteristic of giving different colours when excited by different wave-lengths of ultra-violet light. New glasses have been developed for the special purpose of acting as a 'solder' and enabling, for example, glass, metal and mica to be soldered to glass. Various examples of the use of the new glasses were shown. In another exhibit a surface layer had been applied to glass by a special technique which results in a low electrical resistance together with a high light transmission and low reflexion losses. The conducting layer is extremely resistant to attack by strong chemicals, including hot hydrofluoric acid. Very high frequency (megacycle) sound waves are being increasingly used in a number of industrial purposes; for example, for mixing and emulsifying in chemical and biological processes. Quartz crystal transducers controlled by powerful high-frequency generator units were used in demonstrations.

Progress in atomic physics was demonstrated in a number of exhibits illustrating, for example, new forms of electronic counters, photographic methods of recording nuclear particle tracks, a synchrotron vacuum annulus for acceleration of electrons to energies of 30 MeV., and so on.

The general impression created by the Exhibition is that the scientific instrument industry of Britain is in a very flourishing and healthy condition. The Physical Society, the Exhibition Committee, and the secretarial staff involved in organising the Exhibition are to be heartily congratulated on its success.

A. B. WOOD

CRITICAL BRITISH GROUPS OF FLOWERING PLANTS

THE study of the taxonomy of the British flora has suffered a long period of neglect at the universities, and until very recently its progress has been mainly in the hands of amateur botanists, the British Museum (Natural History) and the Royal Botanic Gardens, Kew. Cytology and ecology have provided the taxonomist with important new tools, and their application has led to a revival of interest in the seats of learning on a scale which would have seemed impossible only a decade ago. The conference on "The Study of Critical British Groups", arranged by the Botanical Society of the British Isles under the chairmanship of its president, Mr. J. S. L. Gilmour, on April 9 and 10, marked a new epoch in the combined application of the new and old tools.

The object of the Conference was to bring together field botanists, herbarium botanists, cytologists, geneticists and ecologists in a demonstration of the new synthetic approach to taxonomy. This was attained by a series of papers covering recent work on the elucidation of 'critical groups', that is, groups of flowering plants in which difficulty is found in defining closely allied species. By the end of the second day it was evident that a very wide variety of methods could be employed and that each group considered provided problems which differed from those of others.

A short introductory talk by the president was followed by three papers covering general aspects of the subject. Dr. E. F. Warburg (Bedford College, London) dealt with "Cytology in Relation to Critical Groups". He showed that plants might be considered according to the number of chromosomes under the following three classes: (1) where the chromosome number is the same throughout a relatively large taxonomic unit as in *Ribes* and *Pinus*; (2) where the chromosome numbers are all multiples of a basic number throughout the group as in *Salix* and *Sorbus*; and (3) where the numbers within a group bear no obvious relation to each other as in *Erophila verna* ($2n = 14, 24, 64$, etc.), *Viola* (pansies with 26, 34 and 48), and the annual *Gerania* (18, 22, 26). The second class is the most common and the most useful to taxonomists. As instances of the value of cytological work in the differentiation of species, Dr. Warburg mentioned Hagerup's separation of the diploid *Empetrum nigrum* from the tetraploid *E. hermaphroditum*, and Howard and Manton's separation of the diploid *Nasturtium officinale* from *N. uniseriatim* with double the number of chromosomes. He also directed attention to the fact that *Oxycoccus microcarpus*, which had been regarded as a mountain variety of *O. quadripetalus* by British botanists, had only half the chromosome complement of the lowland plant, and that Hagerup's work indicated that it should be given specific rank. After stating that imperfect pairing led to imperfect pollen and eggs and often partial sterility in hybrids, and pointing out that suspected hybridity could often be confirmed by examination of meiosis, he directed attention to the important part played by hybridization in the origin of new species and particularly of polyploids. Dr. Warburg instanced *Galeopsis Tetrahit* as a species which had been made artificially by a geneticist. He reminded botanists that in cases like *Spartina Townsendii*, which behaves as a species although of known hybrid origin, the hybrid sign

('×') should be omitted before the name. Finally, he dealt with apomixis, where seed is produced from a diploid cell of the female parent without reduction division or fertilization. In some of our most critical genera, such as *Rubus*, *Hieracium*, *Alchemilla* and *Sorbus*, the polyploid species are usually apomictic, but occasional sexual reproduction occurs and produces new forms.

Dr. W. B. Turrill (Kew) gave an account of "Experimental Studies on British Species of Plants", which was particularly valuable on account of the many suggestions for lines of research which could be profitably followed up. He summarized the transplant experiments carried out under the ægis of the British Ecological Society, and his genetic researches on *Silene Cucubalus* and *S. maritima*, *Centaurea*, *Anthyllis*, *Geum*, *Saxifraga* and *Anagallis*, which had revealed an unsuspected range of variation in British species. He regarded taxonomy as the focus of all branches of botany and stressed that experimental methods must be used as an addition to the old taxonomic methods—they do not supersede them.

The third introductory lecture was given by Prof. A. R. Clapham (University of Sheffield) on "Ecology in Relation to Critical Groups". He pointed out that distinctions of a kind which taxonomists regard as specific cannot be made without barriers to prevent interbreeding. In addition to the cytological barriers already mentioned, interbreeding might be prevented by geographical isolation from climatic and historical causes or by ecological isolation from habitat differences within the same climatic area. Thus *Orchis fuchsii* and *O. ericetorum*, *Galium palustre* and *G. uliginosum*, *Glyceria declinata* and *G. fluitans*, *Empetrum nigrum* and *E. hermaphroditum*, *Oxycoccus quadripetalus* and *O. microcarpus*, and *Viola Riviniana* and *V. Reichenbachiana*, are pairs of species more or less subject to ecological isolation. Recent work has shown that the two British hawthorns are similarly differentiated—*C. oxyacanthoides* being more definitely a woodland species than *C. monogyna* of hedgerows.

The Conference then turned to the consideration of the problems of particular groups. Following the afternoon session when some of the exhibitors gave short talks on the material displayed (see below), Mr. W. C. R. Watson read a paper on "An Introduction to *Rubus*". He discussed the evolutionary trends in the genus as based on morphology and distribution. During the discussion which followed, Mr. A. J. Wilmott (British Museum (Natural History)) directed attention to the prevalence of critical species of such apomictic genera as *Rubus*, *Rosa* and *Hieracium* in areas which had been glaciated.

Dr. D. H. Valentine (University of Durham) lectured on "Vegetative and Cytological Variation in *Viola Riviviana*" with special reference to the production of adventitious shoots from the roots in certain plants. The chromosome number for the species is $2n = 40$, but he had also counted 42, 45 and 46 in material from Cambridgeshire and Durham. There was some evidence that the supernumeraries were associated with the production of adventitious shoots.

The proceedings for the second day opened with a paper on "Intraspecific Categories of Variation" by Mr. A. J. Wilmott. In analysing the collection of such units made for the Systematics Association, he developed important original theories which were received with very great interest. He emphasized that many of the difficulties which arose in discussing the term 'species' came from the use of that word in two discrepant ways, nomenclatural and philosophic. Hence many botanists refuse to recognize as different kinds of species all groups of specific nature—that is, possessing correlated characters and distinct distribution—because if they did so they would have to treat them as nomenclatural species also and give them biverbal names. He therefore proposed the term *biverbum*—a thing with two words—for the latter, and *triverbum* for the lesser unit variously called microspecies, subspecies, or races. The various kinds of intraspecific groups were then discussed, and distinguished from these intraspecific variations which did not produce groups. He emphasized that only discrete natural groups should be given epithetal designations, and suggested methods for designating other units should this be necessary in systematic or other studies.

Dr. K. B. Blackburn (King's College, Newcastle) dealt with "Chromosomes and Classification in the Genus *Rosa*". After outlining the purely taxonomic classifications of De Candolle, Lindley, Crépin, Christ, and others, she gave examples of the use of cytology as a straight taxonomic character. Certain of the Caninæ with $2n = 35$ behave in an irregular manner at reduction division. The odd chromosome gets on to the plate in meiosis and divides—the progeny are fertile. In *R. Richardsoniana* Harrison the eggs have 35 minus 7, and the pollen grains have 7 chromosomes, so that the group can go on with the odd number of chromosomes. Although Gustafsson had denied the occurrence of apomixis, it was reported by earlier workers, and efforts should be made to confirm it.

The paper read by Dr. T. A. Sprague (Kew, retired) on "Forms of *Valeriana officinalis*" described cytological variants which are not certainly distinguishable by morphological characters. He stated that the diploid of the aggregate species with $2n = 14$ was known in Europe, but only the tetraploid and octoploid had been detected in Britain. The two latter showed ecological differentiation, the tetraploid being restricted to oolitic limestone, chalk and carboniferous limestone in the south of England on slopes and dry valleys in hilly regions, while the octoploid inhabited low ground on swampy and more acid soils and had a wider distribution. Certain morphological differences existed but there was much overlapping of characters, and even after considerable experience Dr. Sprague was able to distinguish the octoploid from the tetraploid with only about 90 per cent accuracy. The cytological work was done by Dr. Skalinska, who found that the size of the pollen grains enabled the two to be separated in herbarium material. Reproduction from seed was estimated to produce only about 95 per cent of the new plants, the remainder coming from soboles or occasionally from bulbils.

"Some Taxonomic Problems in *Galium* and *Juncus*" was the title of an extremely lucid paper by Prof. A. R. Clapham. He showed that in *Galium palustre* there was an octoploid with $2n = 96$ and a diploid with $2n = 24$, which differed in morphological characters, ecological requirements, and time of flowering, and approximated to varieties which had been described by taxonomists. The length of the guard-cells of the stomata provided an unusual and almost absolute character. In *Juncus* the diploid chromosome number of *J. acutiflorus* was found to be 40, of *J. articulatus* 80, and of the hybrid 60, as might be expected. But in addition he had found in meadows near Oxford a variant which had vegetative characters nearly those of *J. acutiflorus* and reproductive characters, resembling those of *J. articulatus*, and which was quite fertile. This he had called "Large 80" on account of the chromosome complement, and no satisfactory suggestion had been made for dealing with it taxonomically.

In the last paper of the series Dr. R. W. Butcher (Ministry of Agriculture) considered "Some Problems of Water Buttercups". The aquatic Ranunculi provided an exceptionally good example of the effect of environment on morphology, and by growing them in tanks under controlled conditions he had been able to study the effect of depth of water, exposure to air, and the problem of the production of floating leaves. The study of the variants which occurred in rivers showed that there were probably three species, of which one was new.

Throughout the Conference, exhibits of herbarium material, photographs and diagrams were on view to illustrate features of various critical groups. Dr. Butcher, Prof. Clapham, Dr. Sprague and Mr. Watson displayed material referred to in their papers, and some of the other exhibitors gave short talks. Mr. G. M. Ash directed attention to the convenience of having leaves and dissections mounted separately on small cards for ease of comparison, as shown in his exhibit of *Epilobium*. Dr. K. B. Blackburn showed *Limosella aquatica* and *L. subulata* with the fertile colchicine-induced hybrid between them. She had worked on material from Wales supplied by Miss E. Vachell. Mr. C. E. Hubbard (Kew) spoke on his large series of grasses. His account of variation in *Agropyron* and *Poa pratensis* illustrated difficult problems. Dr. J. M. Lambert (Westfield College, London) described the ecology of *Glyceria* very clearly and directed attention to some remarkable variants she had found. Mr. J. E. Lousley outlined the cytogenetical work done on British species of *Rumex* abroad and indicated a number of problems in which he appealed for the assistance of a cytologist in his studies. His exhibits of wild and cultivated material of the tetraploid *R. tenuifolius* compared with the commoner hexaploid *R. Acetosella*, of the sterility of hybrids of the *Lapathum* subgenus, and of variation coupled with geographical distribution in the subspecies of *R. obtusifolius* and *R. pulcher*, and of variation proved to be due to habitat conditions in *R. maritimus*, illustrated various aspects of the subject. Prof. T. G. Tutin (University College, Leicester) showed material of *Bromus*. A plant which occurs at the Lizard is suspected of being *B. Ferronii* Mabille, which was described from western France. Mr. S. M. Walters (Cambridge) spoke on *Alchemilla*, of which he had recently carried out a revision.

The other exhibits included "Variation and Ecology in the British Watercresses" by Mr. H. K. A. Shaw (Kew), *Carex* by Mr. E. Nelmes (Kew), *Agrimonia* by Mr. N. H. Brittan (Newcastle), *Cardamine* by Miss F. Hussein (Newcastle), groups of British *Rubi* by Miss Y. Massey (Newcastle) and *Mentha* by Mr. R. Graham.

It was with certain misgivings that the organisers had arranged a 'brains trust' to conclude the proceedings of the Conference; but this feature proved an outstanding success. Acting as question master, Mr. J. S. L. Gilmour introduced the members of the trust: Miss M. S. Campbell, Profs. C. E. Raven and T. G. Tutin, Dr. E. F. Warburg and Messrs. J. E. Lousley and A. J. Wilmott—with pseudo-scientific names. The questions ranged from such subjects as the spelling of trivials with small initial letters, and estimates as to the relative greatness of field-botanists of the past, to the definition of an 'over-winter annual'. Although the 'brains trust' was arranged as a less serious item in the programme, there can be no doubt that the opinions provided on controversial subjects were of considerable value.

The outstanding feature of the Conference proved to be the revelation of the deeply interlocking nature of the studies of the very varied botanical interests represented. There was a spirit of eager collaboration among the 114 members and guests who attended. Cytologists were eager to help ecologists, amateur botanists to assist professionals, and *vice versa*. The Botanical Society of the British Isles proposes to foster this synthetic approach to taxonomy and, as the president stated in his concluding remarks, the note of collaboration engendered at the Conference will not be allowed to die.

The officers of the Society and in particular the secretary, Miss M. S. Campbell, and the assistant secretary, Mr. W. R. Price, are to be congratulated on the success of the first Conference arranged by the Society. The comfort of those who attended was ensured by the excellent accommodation provided by the Royal Horticultural Society. J. E. Lousley

EMISSION OF Li^8 IN THE EXPLOSIVE DISINTEGRATION OF NUCLEI

By C. FRANZINETTI and R. M. PAYNE

H. H. Wills Physical Laboratory, University of Bristol

IN a recent communication from this Laboratory[1], it was shown that unstable heavy nuclei are sometimes emitted during the explosive disintegrations produced in photographic plates by the passage of cosmic radiation. In some cases, these unstable particles, after being brought to rest in the emulsion, give rise to two particles of equal range, emitted in opposite directions. The characteristic tracks thus produced were referred to as 'hammer tracks'; and it was suggested that they are due to the emission of a nucleus of Li^8 during the disintegration, for this nucleus is known to suffer β-decay with a period of 0·88 sec.[2], and simultaneously to decompose into two α-particles. Twenty-eight examples of this process have now been observed in this Laboratory, and it has been possible to establish the correctness of the original interpretation of the phenomenon.

Figs. 1 and 2 show two examples of 'hammer' tracks which are of particular interest. In Fig. 1, the range of the heavy fragment is 60 μ, corresponding to an original energy of emission of the particle of approximately 15 MeV. Fig. 2 shows the tracks resulting from a disintegration, produced at the end of its range by a meson, σ. This transmutation results in the emission of two lightly ionizing particles, p_1 and p_2, which are probably fast protons, together with a fragment which decomposes into two α-particles at the end of its range. The photograph thus provides direct evidence for the ejection of Li^8 in the disintegrations produced by mesons.

In Fig. 3, we show the distribution in range of the α-particles observed in the twenty examples now available for measurement. The corresponding distribution, observed by Christy *et al.*[3], in experi-

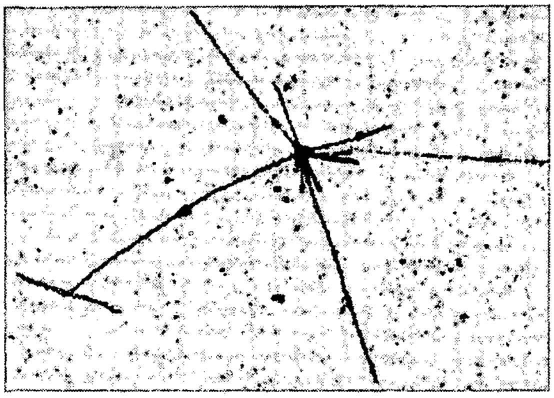

Fig. 1

ments on Li^8 generated in the laboratory in the reaction $Li^7 + H^2 \rightarrow Li^8 + H^1$, is shown by the dotted line in the figure. It will be seen that there is no significant difference in the two distributions. We can, therefore, conclude that the 'hammer' tracks are in fact due to Li^8 nuclei, in accord with the original explanation.

ANALYSIS OF THE 'HAMMER TRACKS'

Number	1	2	3	4	5	6	7	8	9	10	11
Energy of α-pair (MeV.)	4·2	3·8	3·9	5·5	4·3	7·2	5·0	6·7	3·6	2·7	5·8

RELATIVE FREQUENCY OF THE EMISSION OF Li^8 IN THE NUCLEAR DISINTEGRATIONS PRODUCED BY COSMIC RADIATION

Li^8/fission fragments . . .	= 2·28%
Li^8/fission fragments + α-particles .	= 0·37%
Li^8/fission fragments + α + protons .	= 0·185%

The accompanying table shows the details of the measurements made on the individual events. In accord with the explanation of the phenomena given above, the observations show that the directions of motion of the α-particles are orientated at random with respect to the lines of motion of the parent Li^8 nuclei at the end of their range. The table also shows the frequency with which Li^8 nuclei are emitted, as compared with heavy fragments, protons and α-particles, in the 'explosive' disintegrations produced by cosmic rays.

In the β-decay of Li^8, the momenta of the electron and the neutrino, commonly assumed to be ejected during the transformation, cause the resulting Be^8 nucleus to recoil. It follows that if the disintegration of this nucleus into two α-particles takes place in a time shorter than 10^{-22} sec., the two particles should not, in general, be projected in precisely opposite directions. The average difference between the lines of motion of the two particles in the emulsion will, however, only be of the order of one or two degrees. It would be difficult to establish such a difference in the conditions of our experiment, because of the small-angle scattering of the α-particles in the emulsion. As for the difference in energy between the two α-particles, this would be of the order of only a few per cent, and would not be measurable in our experimental conditions.

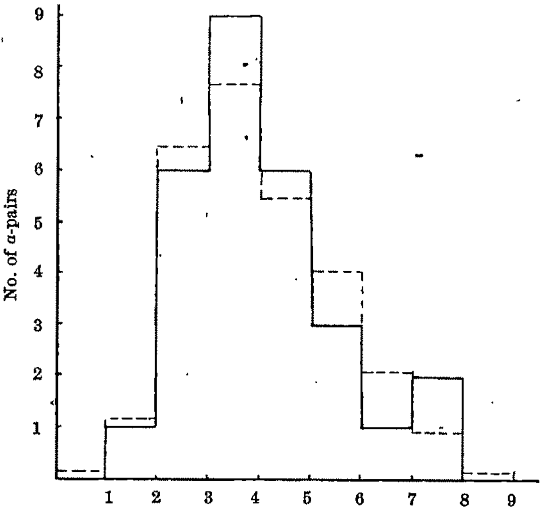

Fig. 3. PRESENT EXPERIMENTAL RESULTS, FULL LINES; DISTRIBUTION OBTAINED BY CHRISTY *et al.*, NORMALIZED TO CORRESPOND TO 28 EVENTS. THE DISTRIBUTION SHOWN IS OBTAINED BY SUMMING THE TWO RESULTS OF THESE WORKERS WITH LITHIUM DEPOSITED ON GOLD AND BERYLLIUM FOILS RESPECTIVELY

In most examples of disintegrations accompanied by the emission of Li^8, it is impossible to identify the original nucleus. Thirteen of the twenty-eight events, however, show that during disintegration, the Li^8 is accompanied by a strongly ionizing particle, probably an α-particle, and a proton. By estimating the energies of the Li^8 nucleus from the known range-energy relation of Lattes, Fowler and Cuer[4], and by applying the principles of the conservation of energy and momentum, it is found that the observations are consistent with the assumption that we are observing the disintegration of C^{12} by a fast neutron.

We are indebted to Dr. C. F. Powell, not only for suggesting this experiment, but also for his continued interest and encouragement; and we take this opportunity of thanking Dr. G. P. S. Occhialini for many helpful discussions and suggestions. One of us (C. F.) was enabled to take part in this investigation by a grant from the University of Bristol, and through the generosity of Mr. A. Giandolini of London.

RHEOLOGY IN THE TEXTILE INDUSTRIES

THE British Rheologists' Club in association with some provincial branches of the Chemical Society, the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Physics, together with the Textile Institute and the Society of Dyers and Colourists, recently organised a two-day discussion (March 19 and 20) on the rheological properties of textile materials. The meetings took place in the Department of Textile Industries of the University of Leeds under the chairmanship of Prof. J. B. Speakman, head of the Department and president of the Rheologists' Club. About a hundred and fifty scientific workers, including a number of overseas visitors, were present, and the problems discussed embraced such diverse phenomena as the flow of fibres over one another in the manufacture of yarns, and the state of orientation of long-chain molecules in viscose rayons.

The first day's proceedings commenced with a paper by D. R. Cox (Wool Industries Research Association) on "Fibre Movement in the Drafting Process". He derived the equations governing the velocity and distribution of the fibres in terms of general expressions for the frictional coefficient of the inter-fibre area of contact, which would depend on the pressure perpendicular to this surface. Only the relatively simple form of the equations was dealt with in the special case of short fibres. He then showed that the initial irregularity of the sliver, characterized by the values of its 'spectra', would be modified by the drafting process so that the spectrum of the issuing sliver could be derived from it by use of the fundamental equations. A single irregularity in the entering sliver was seen to give rise to an emerging wave of irregularities. R. Meredith (British Cotton Industry Research Association) read a paper on "Relaxation and Flow in Cellulose Fibres". The Tobolsky–Eyring–Halsey theory of viscous flow in high polymers was expounded and shown to provide a molecular picture of the delayed elasticity and creep properties of cotton and other such textile fibres. From these phenomena the theory enabled one to calculate the molecular dimensions of the 'flow unit' and the activation energy of the flow process.

Prof. W. E. Morton and F. Permanyer (Manchester College of Technology) then concluded the first session with a paper entitled "Torsional Relaxation in Textile Filaments". The behaviour of a wide range of textile materials had been studied and the data obtained were presented in graphical form. The logarithmic plots of the relaxation of stress with time illustrated the applicability of the Nutting–Scott Blair equations with only a few exceptions.

On the second day, H. J. Woods, R. R. Mukherjee and M. K. Sen (Textile Physics Department, University of Leeds) presented a short paper on "Some Tensile Properties of Jute". Results were given which emphasized the dependence of the values obtained for Young's modulus and tensile strength on the dimensions of the sample chosen. A significant negative correlation, for example, was shown to exist between the Young's modulus and the denier of the fibre (a measure of the thickness), which is in agreement with the 'weak spot' theory. Relaxation in jute fibres was negligible under the experimental conditions. The next paper, by L. Peters and Prof. J. B. Speakman (Textile Industries Department, University of Leeds), on "The Viscous-Elastic Properties of Wool Fibres", proposed a new theory of the elastic properties of wool or other keratin fibres. Unlike the kinetic theories of the elasticity of rubber and related high polymers, where extension is regarded as the transition from a disordered to a more ordered state, the new theory makes use of the X-ray data which indicate that keratin is transformed from one crystalline state to another by unfolding of the main peptide chains. Assuming that these two forms are in dynamic equilibrium with one another, it follows that there must be some of the extended form present even in unstretched fibres. The load-extension curve of wool in formic acid indicates that this is by no means a negligible proportion of the total. Quantitative analysis of the curve was attempted, and estimates of the change in heat content and entropy of stretching have been evaluated. The creep properties are considered to be due to the transference of stress from the 'crystalline' to the 'amorphous' phase.

This was followed by a paper on "Stress-Strain Characteristics of Viscose Rayon in Relation to Anisotropy" by L. Rose and J. D. Griffiths (Messrs. Courtaulds, Ltd.). The outstanding feature of the work is the discovery of a linear relation between the birefringence and the logarithm of the slope of the load-extension curve of the wet rayon. This enables the birefringence of a specimen to be calculated with an accuracy of 0·001 from a simple measurement of wet tenacity and elongation when the axial swelling is known. It was shown that normal 'unstretched' rayons are anisotropic because of the profound contraction which takes place during drying on the bobbin. Under conditions where free contraction takes place, the material is optically isotropic and the properties of the filaments are in satisfactory agreement with the above linear relation.

The final paper was given by F. S. Warburton (Wool Industries Research Association) on "The Mechanical Properties of Horn". He described optical methods of determining the elastic constants of strips of horn with high precision at different humidities.

The papers, and the highly interesting discussions which followed, are to be published in the *Journal of the Textile Institute*.

L. PETERS

RECENT RESEARCH IN MARINE BIOLOGY

THE first number of the twenty-seventh volume of the *Journal of the Marine Biological Association* contains eight papers on varied aspects of marine biology.

Mr. G. M. Spooner and Dr. Segerstråle describe, in independent papers, their investigations on species of *Gammarus*, as the result of which we now have a clear picture of the species and varieties of these important marine scavengers. Mr. Spooner's pre-war studies on the quantitative and qualitative distribution in estuaries of *G. locusta, zaddachi, duebeni, chevreuxi* and *pulex* have been expanded, and linked with the valuable systematic work of Mrs. Sexton. He also had access to the collections of eight zoologists working on different parts of the British and Danish coasts. He distinguishes between the typical forms of *G. zaddachi*, which he calls *G. zaddachi zaddachi*, and the saline or non-hairy forms, which he names *G. zaddachi salinus*. This separation of sub-species clears up difficulties met with by some observers on the range of the species.

Dr. Segerstråle writes on the distribution and morphology of *G. zaddachi* and its sub-species. Using material from the Baltic (Gulf of Finland to Denmark), the North Atlantic (Norway to Newfoundland) and the Arctic (Novaya Zemlya to Greenland), he distinguishes three sub-species of *G. zaddachi*, the oceanic, typical and saline forms. He regards the large arctic species *G. setosus* and *G. wilkitzkii* as allied to *G. zaddachi*.

Dr. R. Gurney contributes notes on parasitic Copepoda of the family Lernæopodidæ, summarizing those with free or with suppressed nauplius stages. He describes the copepodid stage of *Lernœenicus sprattœ*, probably, he thinks, the attacking stage.

There are two fishery papers. Mr. P. G. Corbin gives a comprehensive account of the spawning of mackerel in the Celtic sea, between Land's End and southern Eire. His investigations showed that spawning occurred between mid-March and the end of July, with the maximum in mid-April, spreading east and slightly north from the western edge of the Continental shelf towards Eire and the mouth of the English Channel. The young also moved eastwards.

The pilchard spawns at the mouth of the English Channel from March until December and spreads eastwards likewise. *Sagitta* spp. and *Muggiœa atlantica* were used as zooplankton indicators.

Mr. P. H. T. Hartley writes on the marking and recapture of flounders, with the object of discovering their migrations, distribution and growth-rates. Of the thousand specimens marked in the Tamar and Lynher estuaries in 1937–38, only 152 were recovered in the estuaries. Rewards were offered for their capture, and if brought in alive, they were measured and released. Seven were caught twice and one three times. Most of the fish do not travel far from the area in which they had been marked, but two showed more enterprise, moving up-channel to the east. One of these got as far as Brighton, two hundred miles away. The fish grew very little or not at all during the winter months. In the spring the young moved upstream, the mature fish down to the sea for spawning, but their movements subsequent to spawning vary considerably.

Prof. N. J. Berrill describes the interesting Ascidian *Pycnoclavella aurilucens*, peculiar to the Plymouth area, and recorded by Garstang in 1891. Its colonies are found in shallow water, growing on gorgonians, large hydroids and calcareous algæ. In structure it closely resembles *Clavelina*.

Mr. R. G. Evans, in a continuation of his ecological studies in Cardigan Bay, discusses the influence of wave action on the fauna and flora of twelve selected localities in the Plymouth area. He investigated wave effects on horizontal distribution and vertical zonation, on the size of individuals of certain common species, and on their toleration of exposure to the air. Although many factors make broad generalizations difficult, he establishes the existence of critical levels in the upper zone (between M.H.W.S. and E.H.W.N.) and the lower zone (between M.L.W.S. and M.L.W.N.). In the former many species attain their highest limit, in the latter some littoral species achieve their lowermost limit and sublittoral species their upper limit. The least critical level lies between E.H.W.N. and E.L.W.N., because here all conditions are more regular than in any other level on the shore.

Lastly, there is Mr. D. P. Wilson's paper on *Physalia physalis*, with an account of its occurrence in the British and adjacent seas during the past hundred years, and of its feeding habits. Swarms of this floating siphonophore appeared off our south-west coasts in the summer of 1945, and off La Rochelle in 1946. Mr. Wilson concluded that *Physalia* is wind-borne, not current-driven; that it was blown north from its normal limit of 40° N. latitude. Associated with it were other southern species, from stalked barnacles to loggerhead turtles. From a single specimen sent from the Scillies by Major A. A. Dorrien Smith, Mr. Wilson was able to observe the rolling action of the pale blue pneumatophore, causing wetting of the pink crest in the water, the elongation of the dark blue dactylozooids, and the attachment of the purple gastrozooids to an unfortunate wrasse provided as food for the *Physalia*. This interesting account is illustrated by three of Mr. Wilson's superb photographs of the living animal.

Abstracts of papers published elsewhere, but written from Plymouth, and the report of the Council of the Marine Biological Association complete the volume.

N. B. Eales

NAPLES ZOOLOGICAL STATION

The director of the Stazione Zoologica di Napoli writes to say that the institute is now in full working order again. In 1947 there were fifty-seven visiting scientific workers, of whom nearly half came from countries outside Italy. There were visitors from America, Belgium, France, Great Britain, Greece, Holland, Hungary, Spain, Sweden, Switzerland and Turkey. This variety of guests and the very varied research work being carried on revives the characteristic feature of the institute as a 'permanent international biological congress' in which valuable new contacts are made, both personally and in the symposia which are held from time to time. Advantage of these new contacts has been taken by the staff in obtaining advice for refitting the various departments of the institute. Laboratory facilities have been not only restored but also improved; in this work help has been given by official bodies and learned societies, both in Italy and abroad, and also by the Rockefeller Foundation, the United Nations Educational, Scientific and Cultural Organisation and the International Union for Biological Sciences.

The research work done in 1947, as in the past, stretches the title 'zoological station' to the utmost, for it embraces the whole field of biology. The more familiar fields of ecological, histological and cytological investigations have been extended to the ultra-structure of cell components, and to experimental embryological investigations along new lines. Many workers were engaged on the analysis of behaviour in fish, *Octopus* and Crustacea. Biochemical investigations included studies on molluscan muscles, the metabolism of the electric organ of *Torpedo*, the chemical nature of respiratory pigments in ascidians and annelids and the active principles concerned in the fertilization of echinoderm eggs. These widely different researches were made possible by the variety of apparatus now at hand. In this connexion thanks are due to the Swedish Research Council and the Wenner-Grens Institut for help in obtaining freeze-drying apparatus (Flossdorf and Mudd) for the rapid fixation and dehydration of tissues at low temperatures *in vacuo*, and refrigerating units. These are very useful additions to the constant-temperature rooms recently installed for dealing with problems demanding special temperatures.

The library has been successful in filling the gaps caused by the War. It now contains some 45,000 volumes, including two hundred and fifty periodicals.

The boats used for collecting have been repaired and the regular supply of living material is assured.

The names of the following visitors show that the institute has regained its position as an international centre: J. and A. Runnström, with G. Lundblad as assistant (Wenner-Grens Institut, Stockholm); A. Bohus Jensen (Carlsberg Laboratory, Copenhagen); L. J. Mullins (Berkeley, California), all working upon the physiology and biochemistry of fertilization, partly with radioactive isotopes; S. Hörstadius (Uppsala), physiology of development in sea-urchin eggs; J. Z. Young and B. B. Boycott (University College, London), the behaviour of *Octopus* and effect of operation on the central nervous system; Miss E. M. Brown (Plymouth), parasitic Protozoa; Miss Helen Brown (Cambridge), protein skeletons in invertebrates; H. Nüesch (Basel), Echinodermata.

Intending visitors are asked to write to the Director setting out their requirements, since many of these are now likely to be met from apparatus in possession of the laboratory. Visitors should also communicate with him concerning apparatus of their own which they wish to bring, as the Director can arrange for exemption from duty at the local Customs. He can also give full information concerning arrangements for lodging; and of that characteristic feature of the institute, the 'mensa', which offers the two main meals of the day to visitors at reasonable prices.

ELECTRICAL STIMULATION OF THE NEUROHYPOPHYSIS IN THE CONSCIOUS ANIMAL

G. W. HARRIS (*Phil. Trans. Roy. Soc. Lond.*, B, **232**, 385; 1947) has devised an ingenious and successful method for electrical stimulation of the hypothalamus or neurohypophysis in the fully conscious rabbit.

A small secondary coil connected to two electrodes was placed between the scalp and the dorsal surface of the skull. The stimulating electrode, a fine insulated platinum wire, was passed through a plug accurately fitting a trephine hole of the skull down through the brain in the middle line until its bared tip lay in the hypothalamus or in the neurohypophysis itself. The indifferent electrode lay between the scalp and skull. The coil and electrodes were fixed in the animal at a preliminary operation, and after recovery the animal showed no ill-effects from the presence of the stimulating unit, indeed it appeared to be quite unconscious of it. Animals have lived up to three years with the unit in place.

A primary coil fed from the A.C. mains, when brought near the animal, energized the embedded secondary coil and so electrical stimulation of any desired intensity could be applied by remote control. Positive results, indicating activity of the neurohypophysis, were obtained when the electrode was in the supraoptico-hypophyseal tract or in the neurohypophysis itself. No results were obtained when the electrode tip was more than half a millimetre away from these structures. Stimulation for a period of 5–10 min. was shown to cause inhibition of a water diuresis and an increase of urinary chloride. In female rabbits, during natural or artificially induced œstrus, stimulation brought about a marked increase of uterine contraction, but little or no effect was observed in the anœstrous or pseudopregnant uterus. This is in conformity with the ordinary results of injecting posterior-pituitary extracts.

These results demonstrate clearly that the neurohypophysis in the normal animal can liberate a hormone or hormones which have antidiuretic and oxytocic activity. Particular interest attaches to the oxytocic effect; for, although the oxytocic action of posterior-pituitary extract has long been known as a pharmacological phenomenon, the demonstration that a natural hormone having oxytocic action is ever secreted by the neurohypophysis during life has hitherto been lacking.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Tuesday, May 11

Royal Society of Arts, Dominions and Colonies Section (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. C. B. Symes: "Control of Insect-borne Diseases in the Colonies—some Recent Progress and Future Prospects".

Royal Anthropological Institute (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Raymond Firth: "Religious Belief and Personal Adjustment" (Henry Myers Lecture).

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

Institution of Civil Engineers (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. T. H. Seaton: "Coast Erosion and Sea Defence, with Special Reference to Problems on the East Coast of England associated with the London and North Eastern Railway"; Mr. C. R. Irving: "The Effect of Winds and Tides on Sea Coast Defence Works in North Wales".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. R. Ruddlesden, Mr. E. Forster and Mr. Z. Jelonek: "Carrier Frequency Shift Telegraphy"; Mr. J. A. Smale: "Some Developments in Communication Point-to-Point Radiotelegraphy".

Society of Public Analysts and other Analytical Chemists, Biological Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. A. A. Miles: "Biological Standards".

Society of Instrument Technology, North-West Section (at the College of Technology, Manchester), at 7.15 p.m.—Annual General Meeting; Mr. C. F. Budenberg: "Pressure Gauges with Special Reference to their Selection, Installation and Maintenance".

Wednesday, May 12

Geological Society (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. Frederick Murray Trotter: "Devolatilization of Coal Seams in South Wales".

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Films illustrating various phases of the Petroleum Industry.

Institution of Electrical Engineers, Transmission Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. B. Calvert: "Transformer Economic Efficiency".

Wednesday, May 12—Thursday, May 13

British Ceramic Society, Refractory Materials Section (at the Institute of Mining and Mechanical Engineers, Neville Hall, Westgate Road, Newcastle-upon-Tyne)—Spring Meeting.

Thursday, May 13

Chadwick Public Lecture (at University College, Nottingham), at 4 p.m.—Sir Arthur MacNalty: "Advances in Preventive Medicine during the War of 1939–1945".*

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Discussion on "The Orientation of Birds on Migratory and Homing Flights" (to be opened by Dr. D. H. Wilkinson and Dr. W. H. Thorpe).

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Annual General Meeting.

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6 p.m.—Mr. I. A. Harris: "The Calculation of Electrode Temperatures in the Radio Valve".

British Institution of Radio Engineers, North-Western Section (in the Reynolds Hall, College of Technology, Sackville Street, Manchester), at 6.45 p.m.—Dr. W. E. Boyd: "The Wave Analysis of the Low Frequency Potentials of the Human Body".

Royal Photographic Society, Scientific and Technical Group (at 16 Prince's Gate, London, S.W.7), at 7 p.m.—Symposium on "Reversal Development".

Friday, May 14

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 1 p.m.—Mr. E. M. Gray: "Labour in the Cotton Industry".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

British Association of Chemists, Birmingham Section (at the University, Edmund Street, Birmingham), at 6.30 p.m.—Mr. J. F. J. Dippey: "Observations on the Strength of Organic Acids".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Ian Heilbron, F.R.S.: "The Role of Chemistry in Combating Tropical Diseases".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Head of the Horticultural Department, and a Horticultural Adviser and Lecturer (one Senior and one Junior post)—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (May 14).

Lecturer in Surveying in the Mining Department—The Registrar, The University, Leeds 2 (May 14).

Assistant Analyst—The City Analyst, 152 Great Charles Street, Birmingham 3 (May 15).

Research Awards in the Departments of Botany, Geography, Mathematics and Zoology—The Registrar, University College, Hull (May 15).

Assistant Lecturers (2) in Geology, with special qualifications in either mineralogy and petrology or stratigraphy—The Registrar, The University, Manchester 13 (May 15).

Lecturer in Psychology in the United College—The Secretary, The University, St. Andrews (May 15).

Leverhulme Studentships in Chemical Engineering—The Secretary, University College, Gower Street, London, W.C.1 (May 15).

Lecturer in Geography—The Secretary, University College, Gower Street, London, W.C.1 (May 19).

Lecturer in Physics—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (May 19).

Assistant Lecturer (Grade III) in Geography—The Secretary and Registrar, The University, Bristol (May 22).

Lecturer or Assistant Lecturer in the Department of Geology—The Registrar, The University, Sheffield (May 22).

Assistant Experimental Officers in Scientific Establishments in various Government Departments—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 2162 (May 27).

Lecturer in the Department of Fuel Technology, and a Research Assistant to the Professor of Fuel Technology—The Registrar, The University, Sheffield (May 29).

Superintendent of the Light Division of the National Physical Laboratory—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2154 (May 29).

Senior Lecturer in Theoretical Physics in the United College—The Secretary, The University, St. Andrews (May 31).

Principal Scientific Officer (at Waltham Abbey, Essex) with sound knowledge of chemical engineering and experience of plant design problems in organic chemical technology, and a Principal Scientific Officer (at Sutton Oak, Lancs.) with practical experience of chemical plant design, in the Ministry of Supply Research and Development Establishments—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2160 (May 31).

Principal Scientific Officer in the Royal Naval Scientific Service—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2159 (May 31).

Senior and Junior Fellowships—The Director, Atomic Energy Research Establishment, Harwell, Didcot, Berks (May 31).

Chemical Engineers as Experimental Officers in Ministry of Supply Establishments—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2161 (June 1).

Chair of Social Geography at the London School of Economics and Political Science—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 3).

Lecturer in Agricultural Zoology, and Demonstrators in Agriculture, Agricultural Engineering, Botany, Zoology, Applied Chemistry, Poultry Husbandry, at the School of Agriculture, Sutton Bonington, Loughborough—The Registrar, University College, Nottingham.

Physicist to investigate, in collaboration with senior rheologist, physical properties of bovine secretions—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berks.

Laboratory Steward in the Department of Applied Chemistry—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Lecturer to teach Zoology to B.Sc. generalstandard and to assist in teaching of Biology to first M.B. standard—The Clerk, Northern Polytechnic, Holloway, London, N.7.

Technician (Grade B) in the Pathological Laboratory—The Area Pathologist, Musgrove Park Hospital, Taunton.

Lecturers in (*a*) Physics, (*b*) Botany (a senior appointment with some administrative responsibility), and (*c*) Zoology; Assistant Lecturers in (*a*) Physical Chemistry, (*b*) Physics, and (*c*) Zoology; Demonstrators in (*a*) Physics, (*b*) Botany, (*c*) Chemistry, (*d*) Geography, (*e*) Geology, and (*f*) Zoology—The Registrar, University College, Nottingham.

NATIONAL PARKS IN BRITAIN

THE intimation by the Lord President of the Council in the House of Commons on April 29 that the Government has at long last agreed in principle to establish a Nature Conservation Board and a Biological Service under the auspices of the Agricultural Research Council is both welcome and reassuring. It is not merely that the scientific community has the satisfaction of seeing the principal scientific recommendations of the Conservation of Nature reports accepted. By implication, some effective action must be contemplated in regard to Nature reserves, and possibly national parks also, if the proposed Biological Service is to have an adequate field of work. The statement was the more welcome because earlier replies, given in the House of Commons on April 8 and during a debate on the same day in the House of Lords, gave the impression that the Government was hesitating to take a decision.

Following its recommendation that the prime charge of national parks should be given to a specific central authority, in the form of a National Parks Commission, under the parliamentary responsibility of the Minister of Town and Country Planning, the National Parks Committee recommended that the committee set up for each national park should be designated the local planning authority for that area. The park committee would thus replace the county council or councils in whose area the park lay for the purposes of planning and controlling development, although any important conflict between local and national interests which the park committee could not resolve would be referred to the Minister for his decision. The Hobhouse Report further recommended that the chairman and half the other members of each park committee should be appointed by the National Parks Commission and the other half by the county council or county borough councils whose administrative areas fell wholly or partly within the national park.

Uneasiness, not to say dissatisfaction, has already been manifested in the frequent disputes concerning the land requirements of the Services over the Government's failure either to appoint a National Parks Commission or to take any decision concerning the areas to be designated as national parks. It now appears that the Government has decided on the appointment of a National Parks Commission; but the position with regard to the Hobhouse proposals on local organisation and planning still awaits clarification. Lord Henderson's statement in the House of Lords was not altogether clear; on the ground of the general planning system of the country being in a state of evolution and of the much higher standard of planning anticipated, especially in rural areas, under the new planning authorities set up under the Town and Country Planning Act, 1947, he seemed to commit the Government to accepting the county councils as planning authorities responsible for the national parks, to the exclusion of any National Parks Commission which may be established.

It will be recognized, as was emphasized in the debate, that under the Hobhouse proposals some counties would lose a third or more of their area—one of them more than three-quarters; indeed, some ten per cent of the total area of England and Wales would be affected. It will never be easy to strike the right balance between the different interests—even different national interests—concerned; but the whole trend of the debate in the House of Lords indicated the immense amount of goodwill and the general desire to reconcile interests which might sometimes clash. But no one who has followed, however superficially, the discussions in recent years on local government reform will be satisfied that, if a National Parks Commission has no hand in the planning of these areas, there is no danger that some county councils will allow particular local interests, whether farming, mining or building, to destroy altogether the scenic and amenity interest which is the mainspring of the whole idea of national parks.

Lord Henderson's inability to forecast either the date or the extent of future legislation on this matter was very disappointing in spite of his reference to the hope expressed by the Minister of Town and Country Planning that it would be possible to introduce such legislation during the life-time of the present Parliament. His statement would have been more convincing had he shown some appreciation of the fact that, in making its proposals, the Hobhouse Committee very clearly recognized that it is essential to preserve and to extend the means for the expression of local views and for maintaining local interest. The conception on which its policy and proposals for national parks are based is dynamic and not static, as Lord Henderson implied. The Hobhouse Committee, while emphasizing the importance of national control and a national policy, and that the central management and development of national parks and Nature reserves must be planned from the start in adjustment with other essential interests in the land, such as agriculture, forestry, water supply, communications and building, was equally insistent on the importance of enlisting local knowledge and experience, and encouraging and maintaining local interest and co-operation.

In the absence of any indication that the Government intends to give a National Parks Commission real authority as distinct from merely advisory functions, there is every reason to believe that the county councils will be so firmly entrenched in the proposed national park areas that it will be difficult, if not impossible, to secure for any such Commission a preponderant voice in the planning of the parks. Harm may already have been done to areas of exceptional beauty that will be beyond the power of the wisest and ablest management to repair. Furthermore, if the Minister of Town and Country Planning deals with the whole matter under the Planning Act, as Lord Henderson more or less implied he proposes to do, there will not be unity of control even within such important areas as those proposed for the Lake District and the Peak, which are themselves within the boundaries of several planning authorities.

It is clear from this debate that a coherent system of national parks in Britain is by no means assured, and that little effective may remain of the recommendations which last year received such a friendly welcome from public opinion. No Government could have had at its disposal a greater volume of expert advice and of objective study in these matters. In spite, however, of something approaching its intense activity in the nationalization of industry, the Government is singularly indifferent to the dangers of drift and of unco-ordinated action in matters affecting the utilization of the land, and seems reluctant to insist on the national control that is imperative and has been urged by such impartial authority. Even in the matter of Service land requirements, the Government has consistently ignored the need for providing some means for overall review and for avoiding piecemeal encroachment on other national interests. Both in the White Paper on the "Needs of the Armed Forces for Land for Training and Other Purposes", and in debates in the House of Commons on specific proposals, Government spokesmen have studiously avoided giving any positive reply to direct questions regarding national parks and National Trust property.

The case for a National Parks Commission with full statutory powers, and the importance of the time factor in this connexion, was ably put by Lord Merthyr in opening the debate. Quite apart from the question of Service lands, mineral developments, afforestation and hydro-electric power or water-supply developments, it may well be too late, as Lord Merthyr observed, if we wait until the building restrictions are lifted before establishing national parks. Lord Merthyr was ably supported by Lord Samuel and others, and while Lord Rochdale and Lord Roborough in particular advocated use of the planning organisation laid down in the Town and Country Planning Act, 1947, it was generally recognized that means must be found for securing the co-operation of local communities and authorities in order to achieve the national purpose, whatever degree of authority is given to a National Parks Commission.

Some of the criticism of the Hobhouse Reports as well as of the Huxley Report on the conservation of Nature in England and Wales and the reports of the Scottish National Parks and Wild Life Preservation Committees suggested that the speakers have not studied these reports with sufficient care. Despite some differences in several recommendations, they all agree as to the necessity for a national policy and control, and that a national parks policy must be considered in relation to other national interests affecting the use of the land and the exploitation of natural resources. Nor could the importance of securing local understanding and support be better urged than throughout the reports. Lord Robinson, and with him Lord Hylton, may have been right to suggest in the debate that further consideration should be given to the use of the land for agriculture and other purposes in our present economic position; but the suggestion that the Hobhouse Committee had overlooked such considerations, and had taken a static view of the question likely to lead to sterilization of the areas to be allotted as national parks, is surely inaccurate.

What is clear from the debate, as from the reports, is that the balance between national needs in respect of land for agriculture, water supply, afforestation, minerals and the like must be struck at the national level, and not piecemeal by either departmental, local or sectional interests. The proposed National Parks Commission can make a vital contribution in arriving at that balance, from the point of view of amenities, the preservation of wild life and scientific interests. Furthermore, the whole trend of Lord Roborough's remarks indicates, as Lord Methuen quickly noted, that even in such an extreme case as that of Devon and Dartmoor, there should be little difficulty in reaching an agreed solution under the Hobhouse Committee's proposal, and securing the efficient and whole-hearted co-operation of the county council in the planning and management of the national park.

Nothing in the debate, therefore, warrants further delay on the part of the Government in the creation of a National Parks Commission or in determining the areas of the parks themselves. On the contrary, the debate gave clear warning to the Government of the dangers of delay, and of the shock that public confidence in its good faith in this matter has already received. The Government has taken care in many matters to provide itself with expert and impartial advice. Failure to act on such advice, above all in matters which are not the subject of party controversy, and where, as in the matter of the Huxley Report and those of the Hobhouse Committee, inaction itself prejudices the issue, must react adversely on the understanding and good relations which the Government has often been at pains to foster with the scientific community.

COSMIC RAYS

Cosmic Rays

By L. Jánossy. (International Series of Monographs on Physics.) Pp. xiii+424. (Oxford: Clarendon Press; London: Oxford University Press, 1948.) 35*s*. net.

THE study of cosmic rays is one to which scientific men in very many countries have contributed materially. It is therefore fitting that the book under review should have something of an international character: its author, Prof. L. Jánossy, came to Britain from the Continent, and spent several years at Manchester before taking his present post at the Dublin Institute for Advanced Studies.

Most of the book was written during the last years of the War, when, because of the slowing down of cosmic-ray research, a comprehensive view of the whole subject was more readily attainable than in more normal times. The author has given a reasonably complete picture of the state of the subject as it then was. All the material to be found in reports and books published before the War is here also: experimental work on transition effects, showers, cosmic rays at great heights or depths, and the influence of the geomagnetic field. In addition, more ecent work is also reported, such as that on the properties and life of the meson, and on extensive and penetrating air showers. The recent work at Bristol, using photographic methods to investigate meson behaviour, is briefly reported in an appendix.

The book is an experimenter's book; experimental physicists would, however, have grounds for grievance if the impression were given that it was simply an experimenter's book. While much time is spent on the observations, and an important chapter is devoted to experimental technique, a large part of the book is devoted to the theory needed in interpreting the observations. A relativistic theory of collisions is given, for, without going into relativity, even a qualitative interpretation of cosmic rays is impossible. In discussing radiation, semi-classical methods are used: where quantal results are needed, they are quoted without proof, with an indication of their relation to the corresponding classical results. A few hints on meson theory are given, but only enough to whet the appetite. The theory of cascades is discussed in detail: in this, the author plunges fearlessly into Laplace transforms, and the evaluation of complex integrals by residue and saddle-point methods. In the chapter on geomagnetic effects, Störmer's theory of the forbidden cone is set out; and statistical ideas necessary in interpreting the experiments are explained in another appendix.

But theory to Jánossy means a useful adjunct to experiment, not speculation. He comes closest to speculation in introducing the sun's magnetic field. In so far as the book has a guiding thread running through it, it is that the primaries giving rise to observed cosmic rays have a momentum spectrum given by an inverse power law, cut off at the low-energy end by an agency supposed to be the sun's magnetic field. But the inverse power spectrum cannot, in any event, extend to low energies, since it would give an infinite number of low-energy particles, and one wonders whether the energy cut-off need be so sharp as Jánossy suggests; and the properties and precise magnitude of the sun's field are still open to some doubt.

A book discussing so wide a range of subjects as the present cannot fail to be difficult. Unfortunately, the author has made it harder than need be. The style is very variable: while fluent in some places, in others it is disjointed and crabbed, and there is little to suggest the excitement which first attended the discovery of the positive electron and the meson. Needless repetitions abound: the first (historical) chapter is the worst in this respect. The author seems not always clear how much prior knowledge to assume; the first chapter is scarcely intelligible unless one already understands something about transition effects, coincidences, Geiger counters, positive electrons and mesons, all discussed in detail later; while in the middle of Chapter 6, after already giving long chapters on the general properties of cosmic rays and on meson decay, the author suddenly says, in a Micawber-like burst of confidence, "Photographs . . . show clearly that the cosmic rays consist of two groups of particles: (1) penetrating particles, (2) electrons". Altogether, one feels that the book could have been improved considerably by due care in arrangement.

Nevertheless, the author has taken great pains to ensure that the book is as comprehensive as possible, and has succeeded in bringing together and correlating a large mass of useful information. There is little doubt that it will be indispensable to research workers, and will serve to stimulate further the growing interest in the subject. T. G. COWLING

THE STORY OF JADE

Adventure in Jade

By James Lewis Kraft. Pp. ix+81. (New York: Henry Holt and Co., 1947.) 3.50 dollars.

JADE was used for ornaments and tools by the native peoples of Mexico, Central America and Peru, by the Indians of British Columbia, and by the Eskimos. The source of the jade was something of a mystery. In the absence of any known sources—either of nephrite or jadeite—on the American continent, it was supposed, up to ten or twenty years ago, that the jade used by the Eskimos and also that of the Maya and other Central and South American peoples had been brought in from Asia. Of late years, however, some localities for jade have been found in the United States, and Mr. J. Lewis Kraft tells the story of these discoveries.

The subject of the book is of particular interest to Americans not only because of this problem of the origin of the ancient worked articles of jade, but also because there has grown up in the United States a widespread and very active interest in all kinds of semi-precious stones. All over the country there are now local societies and clubs the common interest of which is the search for semi-precious stones and the fashioning of these stones into cabochons and faceted stones for collection specimens or jewellery. Many amateur lapidaries have acquired great skill at this work, and Mr. Kraft is one of these.

His book is not deeply scientific. It is the story, simply told, of how a very busy man found an absorbing interest in jade and the fashioning of it with his own hands into pieces for his collection, presents for his friends, and jade rings as awards for merit to his "fellow workers at the Company". There is much of legend and folk-lore in the book and tales of miners and prospectors and their finds. The author has encouraged or persuaded several prospectors to search for jade, giving them fresh clues to follow or urging them to penetrate to such remote regions as Jade Mountain in Alaska, discovered by George M. Stoney so far back as 1886 but scarcely ever visited since. In Wyoming, nephrite was found near Lander in 1931, and two other occurrences in that State are recorded in this book. An immense boulder weighing 2,490 lb. from Crooks Mountain, fifty miles south-west of Lander, was removed under the author's supervision, transported to Chicago and presented to the Natural History Museum there in 1944.

Ten years ago Pabst's "Minerals of California" contained no record of jade; now the author describes four localities in California from which he has obtained good nephrite. The story of one of these finds reads like the discovery of the first diamond in South Africa. In 1880 a hunter after sea lion entered a cave on the coast of Monterey County. Finding the cave-floor covered with shining green pebbles, he took some home. Fifty or sixty years later a visitor to the hunter's home noticed the children, grandchildren of the hunter, playing with the pebbles. Being interested, he took some back to Stanford University. They were identified as nephrite, and afterwards an enterprising search resulted in the rediscovery of the cave and the recovery of some of the nephrite pebbles and boulders which strew its floor.

It seems that at all these Californian localities the jade is nephrite, so the source of the jade used by the Mexicans, which is largely jadeite, is still to be found. One feels sure that Mr. Kraft will leave no stone unturned until he solves this problem too.

Special care has been taken in the design and type for this book, and the result is a fine example of modern printing. All the royalties will go into a charitable trust.

PHYSICAL PLANNING IN THE SOUTH-WEST OF ENGLAND

Devon and Cornwall

A Preliminary Survey. A Report issued by the Survey Committee of the University College of the South-West, Exeter. Pp. iv+318. (Exeter: A. Wheaton and Co., Ltd., 1947.) 31*s*. 6*d*. net.

IN the provisions of the Town and Country Planning Act, 1947, Britain is committed to the planning of the use of every acre of its land surface, and the county authorities become the primary planning authorities. They are required to put forward their proposals for the approval of the Minister within a brief space of time, and there is a very real danger that far-reaching decisions on policy will be taken with a totally inadequate foundation of factual knowledge. It is therefore of the utmost importance that surveys such as this volume on Devon and Cornwall should be undertaken and made available at the earliest possible opportunity. There is an obvious advantage in such work being undertaken by independent groups with no preconceived points of view and with no axe of their own to grind.

Like the survey of Herefordshire previously issued by the West Midland Group, this survey of the south-west has been undertaken by a representative survey committee, headed by the principal of the University College of the South-West, Exeter, and including both members of the College and experts from outside. The result is a comprehensive account, well documented, adequately provided with statistical information and with a number of excellent maps and diagrams covering the two counties. Published or other documentary material has been supplemented from the results of field surveys, notably one carried out by groups from the College in 1944. Particularly instructive are the attempts to show on a cartographical basis the spheres of influence of the urban centres in these two rural counties. In places the point of view is that of the townsman visiting the country rather than that of the dweller in the village, and it would be possible to criticize in detail some of the maps, as well as some of the information, particularly regarding that rather remote area of north-east Cornwall and adjoining parts of Devon, where the text and maps suggest a stagnation of social life rather far from the experience of those who know the area intimately from within.

There is no indication as to the authorship of the individual sections, and one wonders whether the general conclusions of the excellent first section on population are those of the whole group or of the individual responsible, especially when one reads "The whole emphasis should be on providing the country with the amenities of the town". Further the separate contributions tend to be distinct essays rather than a connected whole. Whereas some summarize published information, others contain much original material. The section on climate is inadequate; that which deals with fisheries is excellent in its scope and treatment, though it is difficult to understand why there should be no recorded landings of fish at Bideford, which in pre-war years was a favourite resort on market days of those who bought their fish fresh from the fishermen on the quayside.

Apart, however, from such minor criticisms, there can be nothing but praise for a volume which embraces such a wide field and which presents in small compass a collection of facts absolutely invaluable and essential for all planning work.

L. Dudley Stamp

ALGEBRAIC GEOMETRY

Foundations of Algebraic Geometry

By Prof. André Weil. (American Mathematical Society: Colloquium Publications, Vol. 29.) Pp. xix+288. (New York: American Mathematical Society, 1946.) 5.50 dollars.

ALGEBRAIC geometry, in spite of its beauty and importance, has long been reproached for lacking proper foundations. Great discoveries have been made, especially in Italy, by the intuition of a number of gifted workers, whose insight had been cultivated by a careful study of special cases. But the time for placing the subject on a firm foundation is long overdue, and the delay is seriously hampering progress. For the last twenty years a few geometers, such as Severi, van der Waerden and Zariski, have made important contributions towards this end. Now Prof. Weil has given a connected and comprehensive account of his own and other researches, sufficient to justify the use of intersection-multiplicities, which play such a large part in recent geometry, especially in Italian work. The book is not easy reading, especially for those to whom geometry is synonymous with space-intuition. At a first glance the reader might imagine that it is a treatise on something like abstract algebra. Indeed, the author warns the reader that it is necessary to have a good elementary knowledge of abstract fields and of other topics that will be found in van der Waerden's "Moderne Algebra". Apart from this the book is self-contained, and its subject is not abstract algebra, but what might be called abstract geometry.

The first three chapters are preliminary; they state and prove all the purely algebraic results required. In particular, Chapter 3 gives the crucial theorem on the multiplicity of a proper specialization. Geometric language is introduced in Chapter 4, which deals with algebraic varieties in affine spaces. Chapters 5 and 6 contain a careful and detailed treatment of intersection-multiplicities.

Chapter 7 extends the definitions and results of previous chapters to 'abstract varieties'. It also translates the main results of intersection theory into a new language, the 'calculus of cycles', which is particularly well adapted to applications. The author points out the confusion that has arisen by the use of ambiguous terms, and endeavours to do away with this by introducing new terms such as 'bunches of varieties' and 'cycles' instead of the single term 'reducible variety' used in two different senses. The term 'variety' is reserved for 'absolutely irreducible algebraic varieties'. An algebraic calculus of cycles can then be developed, closely analogous to the algebra of homology-classes as used in modern topology.

Chapter 8 gives a detailed treatment of the theory of divisors on a variety. Chapter 9 contains general comments on the preceding work, formulates problems, some of considerable importance, and in some cases makes suggestions which may lead to their solution.

H. T. H. Piaggio

PRIVATE LIVES OF THE ALCHEMISTS

The Alchemist in Life, Literature and Art

By Prof. John Read. Pp. xii+100+30 plates. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1947.) 10s. 6d. net.

THE practical operations of the alchemists and their main theoretical beliefs are familiar, in outline at least, to every student of chemistry. The chemical historian may be as familiar with alchemical technique and ideas as the average chemist is with the modern technique of his science. Few, however, have any clear picture of the alchemist as a human being, an individual with a private as well as a professional life. This picture has been skilfully and entertainingly drawn by Prof. John Read in the book under notice, and there are not many, either men of science or laymen, who will not derive both pleasure and profit from reading this scholarly little work.

As the title indicates, Prof. Read draws his material from three main sources. First, there are alchemical biographies, unfortunately all too few, such as Thomas Norton's "Ordinall of Alchimy" and Simon Forman's personal diary. Second, there are the artists who sought inspiration in alchemical themes and have left us invaluable records of the appearance of alchemical laboratories and those who worked in them. Outstanding among these was David Teniers the Younger, to whom the author appropriately dedicates his book. Finally, there are the writers who introduce alchemists and their assistants as characters in their works. Few modern chemists would regard Chaucer's "Canon's Yeoman's Tale" as an important piece of alchemical literature without Prof. Read's skilful analysis and apt quotation. He shows that, in fact, this tale contains a vivid picture of both the charlatan alchemist—the mere puffer or bellows-blower—who will stoop to selling a fake formula to a credulous priest, and also of the genuine alchemist who, even if his ideas are coloured by the hope of discovering the Philosopher's Stone, is, in fact, a serious seeker after knowledge.

As we may expect, the alchemist in his private life conformed to no particular type in mind or body. We have the libertine Forman, for ever guiding his amorous ventures by reading special mystical meanings into the events of his daily life; the cheating Subtle, in whom Jonson holds up to shame and ridicule the alchemical charlatans of his time; the melancholy and frustrated beings portrayed by Dürer and Teniers; the fanatic in threadbare clothes with complexion of "wan and leden hewe" after long hours at the furnace, ignoring the pleas of his starving family; and that fantastic international adventurer Seton, the "martyr of alchemy".

Publisher and author are to be congratulated. After several years of austerity productions, it is a pleasure to take up a book which is so attractively printed and so well illustrated (with the exception of the frontispiece in colour). This attention to detail extends even to the dust-cover, which is of a very pleasing design. T. I. W.

CONTACT LAMINATED PLASTICS

Low-Pressure Laminating of Plastics

By J. S. Hicks, assisted by R. J. Francis. (Reinhold Plastics Series.) Pp. ix+162. (New York: Reinhold Publishing Corporation, 1947.) 4.50 dollars.

THIS small book is to be welcomed as it is the first devoted entirely to the new techniques for moulding by laminating under comparatively low pressure. Starting with the almost inevitable definition of plastics, and disposing of all but the polyesters and related resins in little more than half a page, the author proceeds to describe the moulds used, the resins available, the procedures followed, the finishing of the objects made and the commercial aspects of these new methods. One excellent feature of the book is the large number of photographs illustrating both the stages in production of mouldings and the types of objects that result from them. Since manufacturers are frequently in doubt as to the type of goods for which low-pressure methods are suited, and it is presumably to manufacturers that the book is addressed, the book will serve a useful purpose in bringing home to industry the considerable scope offered by these new methods.

It is, therefore, all the more to be regretted that the book has been written so uncritically and in such a turgid manner. In almost every case where a number of alternative procedures are possible, they are enumerated without the outstanding merits or limitations of any one being considered. Plaster moulds have their advantages, but one could forgive a reader of Chapter 2, new to the subject, wondering why metal moulds are ever considered when plaster is available. Again, the lists of references are formidable and appear to contain all the important papers up to mid-1946, but they are so cluttered up with the titles of papers which were never worth the publishing that much of their value is dissipated.

Many subjects are treated in unexpected places, and the text abounds in irrelevant matter that makes reading difficult.

It is not surprising that the author, coming from Owens Corning Fiberglass Corporation, should devote most of his space to glass fibre cloth laminates, since this company has played a very important part in developing these techniques and is completely responsible for launching several of them; but the title suggests a wider field. Other materials are mentioned but are not given the importance they deserve. To-day more than half the supply of contact resins in the United States goes with paper to the making of continuous laminated sheet. This was not so in 1946, yet even at that time the process deserved a better fate than that of being treated under the heading of 'post forming' and being illustrated by such an inadequate and inaccurate diagram.

The book can be recommended to the people for whom it was written because it is the only one in the field and because there is a need for such a book. To these it will prove well worth its purchase price.

J. M. J. ESTEVEZ

DERMATOLOGY

Modern Trends in Dermatology

Edited by Dr. R. M. B. MacKenna. Pp. xiv+432. (London: Butterworth and Co. (Publishers), Ltd., 1948.) 42s. net.

THIS book might serve as an obituary notice to descriptive dermatology. The only chapter in which description of lesions is a feature is that by Dr. F. Parkes Weber on "Necrobioses, atrophies, scleroses, infiltrations and accumulations in the skin and subcutaneous tissue". It is not implied that the descriptive studies of the past, brought to perfection by Brocq and his followers, can in future be ignored. Without the ability properly to classify skin diseases from a knowledge of surface and cellular anatomy of lesions the practice of dermatology is impossible.

Classification of skin diseases is now becoming clearer and the general trend in dermatology is, as demonstrated in this book, towards biochemical, pathological and bacteriological investigation on a scale never before contemplated. Descriptive dermatology is not yet complete, however, and there might profitably have been included descriptions of such items, apparently unknown or unrecognized in Britain, as Gougerot's syndrome and Koenen's tumours (found in some cases of epiloia). It is a pity that British dermatologists are not provided with any survey of world literature comparable with that available to the French in the admirable abstracts in *Les Annales de Dermatologie et de Syphiligraphie*.

Dr. MacKenna refers in his introduction to the fact that rare diseases receive much more study than do the common ones. His point is confirmed in the book, where the only common conditions fully discussed are the 'seborrhœic' eruptions (by Dr. H. W. Barber).

The widening scope of dermatological research and practice is indicated by chapters on "The Prevention of Cutaneous Diseases, excluding Industrial Maladies", by Prof. F. A. E. Crew; "The Rehabilitation of Patients Suffering from Cutaneous Disease", by Dr. F. F. Hellier; and "Psychological Aspects of Dermatology", by Dr. E. Wittkower. This last chapter is the best short account of the problem of neurodermatosis that I have read. Another outstanding chapter is that by Dr. L. Schwartz on "Occupational Dermatoses".

Dr. MacKenna is to be congratulated on his choice of collaborators, British and American, who have produced an excellent review of the modern trends and advances in dermatology. It is to be hoped that its success will merit further editions on the same lines as the need arises.

My only criticism is that there is no mention of that common skin disease, syphilis, which, in Britain, has become almost divorced from dermatology. Dermatology could be learnt from a study of syphilis and its differential diagnosis, and the dermatologist who does not know all about syphilis—and this is not rare—cannot be a master of his art.

JAMES MARSHALL

Electrons (+ and −), Protons, Photons, Neutrons, Mesotrons and Cosmic Rays

By Robert Andrews Millikan. Revised edition. Pp. x+642. (Chicago: University of Chicago Press; London: Cambridge University Press, 1947.) 30*s.* net.

THIS book is a revised and enlarged edition of Prof. Millikan's book "Electrons" which appeared in 1935, and was itself based on his celebrated work "The Electron" (1917), which in its day occupied a unique position in the literature of atomic physics. It is pleasing to note that the early chapters of the new edition still conform closely to the text of "The Electron", for they contain one of the few accurate accounts in English of the early history of the measurement of the atomic charge. The first fifteen chapters are essentially the same in the new edition as in the 1936 edition, except for emendations to the text, the most important of which is to the value of the atomic charge as obtained from observations of falling drops. This now appears as $e=4{\cdot}807\times10^{-10}$ E.S.U. It is also stated that the value $e=4{\cdot}803\times10^{-10}$ E.S.U. obtained from a comparison of X-ray diffraction from a ruled grating and a crystal lattice is the more precise.

The book is essentially a text on modern atomic physics with special emphasis on the discoveries of the various fundamental particles, and of cosmic rays. The new edition differs from its predecessors in giving more recent information in five additional and valuable chapters, which include a brief discussion of the utilization of nuclear energy and its international control.

The material is everywhere clearly and vividly presented with many illustrations, but the use of the first person singular throughout has rendered it difficult for the author always to give the impression of that scientific detachment which is desirable in an introductory text. L. G. H. Huxley

British Sources of Reference and Information

A Guide to Societies, Works of Reference and Libraries. Compiled under the direction of a Committee of ASLIB and edited by Theodore Besterman. (Published for the British Council.) Pp. vii+56. (London: Association of Special Libraries and Information Bureaux, 1947.) 6*s.*; to ASLIB members, 5*s.*

THIS useful desk tool could have been much more useful had its scope been limited and the defined objectives kept closely in mind. The accounts of the National Central Library, the copyright libraries and library organisations are admirable and adequate, though the references to the Association of Special Libraries and Information Bureaux itself and to the British Society for International Bibliography are already out of date. The sections covering the university libraries and the public libraries of Britain are also adequate although some expansion would have been welcome, particularly as Colonel Newcome's book and the "Yearbook of Learned Societies" are out of print. It is the 'select' list of special libraries that is most open to criticism. No attempt is made to indicate the basis of selection, but while it may be pardonable to omit St. Deiniol's Gladstone Memorial Library at Hawarden, it is difficult to know what to make of a list which omits, for example, the John Ryland's Library in Manchester or the libraries of the Manchester and of the Newcastle-on-Tyne Literary and Philosophical Societies and includes a number of bodies without a library at all. If the compilers in future editions discard the list of general works of reference, leaving this field, for example, to L. McColvin's "How to Find Out", and give the space thus saved to the sections indicated, the value of a promising little guide will be considerably enhanced.

R. Brightman

Manual of Mathematics and Mechanics

By Prof. Guy Roger Clements and Prof. Levi Thomas Wilson. Second edition. Pp. ix+349. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 3.25 dollars.

THIS manual, first published in 1937, has an unusual title, but, as the authors point out in their preface, the book "contains facts and formulas that are useful in courses of mathematics and mechanics in colleges and engineering schools, arranged and presented in a form that makes them readily available for *rapid work with minimum eye strain*". Here we have the key to the title, for the book is not a text-book in the generally accepted meaning of the term. This is the second edition, and consists of many useful tables and formulæ for reference, covering algebra, trigonometry, calculus, statics, kinetics of a particle, and the dynamics of rigid bodies. In the new edition, the section on spherical trigonometry has been expanded to include the needs of courses in navigation. New matter has also been added to meet the demand of the applications of mathematics to electrical engineering, including radio circuits, while formulæ and tables have been appended to meet special demands of courses in physics. The book is therefore very comprehensive, and excellently printed in clear type so that essential data may be readily selected. This applies especially to the many tables provided.

There is room for a book of this nature, provided it is properly used and does not displace the legitimate text-book. Such a reference book is really most useful to the student who has completed courses in mathematics and mechanics and thus has an intelligent fundamental knowledge of the principles upon which the various results here quoted are based. It would be profoundly dangerous to use a book of tables and formulæ as a text-book. With this reservation, the volume may be confidently recommended as a comprehensive and useful adjunct for mature students.

An Analysis of Volitional Life

By C. Lambek. Translated from the Danish by Agnete Kortsen. Pp. 104. (Copenhagen: Einar Munksgaard; London: Williams and Norgate, Ltd., 1947.) 8 Danish Cr.

ONE of the great difficulties of pure introspective psychology has always been the function of the will. The processes of motivation in the human being are complex and elusive if only consciousness is to be considered. Indeed, the exponents of dynamic psychology have suggested that this is due to the strength of the unconscious, and have propounded the well-known analogy of conscious volition being regarded as comparable to a baby on an elephant, the baby (consciousness) believing that it controls the behaviour, but the elephant (unconscious) in reality going where it wishes.

In this book a Danish psychologist attempts to define and dissect the nature of will. He disregards the possibility of feeling-tones (emotions) being the cause of voluntary acts, and states that the intellectual, emotional and volitional processes are all interdependent and of equal importance. He believes that the spontaneous urgency of tendencies to develop is due to the presence of thought images and sense impressions, but that there are ancillary factors, stamps of attention and stamps of vitality, which result in variations of tension. Once motivation is started it is followed up by planning and execution, which indicate future changes and the order in which they are to take place.

This book unfortunately shows the superficial limits of introspective psychology and is not likely to interest the medical psychologist, but it may be of some interest to those studying pure classical psychology; although even those will find little new here. It is well produced, the paper and print are excellent, and the translation is well done.

CLIFFORD ALLEN

Sequential Analysis

By Prof. Abraham Wald. Pp. xii+212. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 24*s*. net.

SEQUENTIAL sampling methods were developed during the War and remained secret for some time. Accounts of the methods have since been published in statistical journals, and knowledge of them has been fairly widely diffused by lecture and discussion both in the United States and in Great Britain. Hitherto, however, there has been no systematic account in book form of the theory of the subject developed from first principles, and Prof. Wald's book is therefore a very welcome addition to statistical literature.

The book is in three sections. The first opens with the elements of the current theory of testing statistical hypotheses, and develops a general theory of sequential probability ratio tests. The second applies the general theory to special cases such as testing means and variances in sampling from normal variation. The third considers the problem of multivalued decisions and sequential estimation.

Prof. Wald writes as a mathematician, lucidly and carefully, with an obvious twinge when the necessities of a simple exposition force him to deviate from complete rigour. Practising statisticians will find it useful to study the book in combination with the bound set of reports (*SRG* 255) on applications of sequential analysis issued by the Columbia University Press (see *Nature*, **157**, 642; 1946).

M. G. KENDALL

Recent Advances in Sex and Reproductive Physiology

By Dr. J. M. Robson. Third edition. Pp. xii+336. (London: J. and A. Churchill, Ltd., 1947.) 21*s*.

IN the new edition of Dr. J. M. Robson's work, he has succeeded admirably in bringing the subject up to date, and the book has benefited by the inclusion of references to the more important papers which have appeared since the last edition. This is well seen in the account of the steroids, where it is shown that there is a relation between the chemical structure and the physiological action of all the hormones or hormone-like substances belonging to this class. The account of the probable factors in parturition is also especially interesting. Here the author points out that in various species the response of the uterus to oxytocin increases progressively during gestation and reaches a maximum at parturition, and the recent researches of Haterius and Ferguson are duly quoted. The factors concerned in ovulation are also discussed, and the evidence of a pathway from the hypothalamus in the brain to the anterior pituitary through the stalk is referred to. Chapter 10, on "Hormone Production and Excretion" under various conditions, and Chapter 13, dealing with "Clinical Applications", are particularly valuable.

F. H. A. MARSHALL

Severn Tide

By Brian Waters. Pp. vii + 183 + 16 plates. (London: J. M. Dent and Sons, Ltd., 1947.) 15*s*. net.

THE title of this book is perhaps slightly misleading. It is not a hydrographical treatise giving all the details of the propagation of the tide in the Severn, with ranges of tide, times of rising and falling, and so forth. Its main object is to relate the activities of the residents on the banks of the river to the flow and ebb of the tide. Nevertheless, the author gives many details regarding the famous Severn bore which are not to be found elsewhere; but these are scattered among many other things. It is as though the author takes the reader on a pilgrimage up and down the river, and in a leisurely way talks with all and sundry, exhibits interest in the details of their lives and occupations, their fishing and their farming, and so on, with intimate touches on how the tide in this river influences their lives.

It is a pleasant book, with much human interest, and it is one of those things which needed to be done, and has been well done. The age of craftsmanship is nearly gone, and the author has recorded many little details (for example, the particular shape of the bend in the handstaff of the lave net, and how such staffs are obtained) which are of interest to those interested in arts and crafts. This book will interest all who know the Severn, whether they be interested in the peculiar problems of navigating a boat with the bore, in fishing, in river lore, or in the intimate details of local life.

A. T. D.

Bibliography of the Technical Literature on Silk

By Dr. F. O. Howitt. Pp. xxiv+248. (London: Hutchinson's Scientific and Technical Publications, 1947.) 21*s*. net.

THE book is precisely described by its title. It is the result of a literature survey which Dr. Howitt undertook after his appointment as head of the Silk Section of the British Cotton Industry Research Association in 1936. At that time there was no systematic review of the widely scattered scientific and technological literature on silk, but Dr. Howitt has now made it possible to claim that the literature on silk is better documented than that relating to any other textile fibre. Starting with the cultivation of silk, he proceeds to discuss the properties of raw silk, sericin and fibroin. Then follow chapters on the preparation of nett silk yarns, degumming, weighting, dyeing, weaving, knitting and finishing. The book ends with a survey o testing methods and a brief reference to non-textile uses of silk. So thorough is Dr. Howitt's treatment of his subject—there are 528 references in the fifty-six pages devoted to the properties of fibroin—tha reading would have been difficult if the informatio had not been so well co-ordinated. The author ca be congratulated on his contribution to the newe scientific literature on textile materials and processes

J. B. SPEAKMAN

HUMAN FACTORS IN INDUSTRY

CONFERENCE AT LEAMINGTON

IN the Assembly Rooms at Leamington Spa, on May 8, the British Association's Division for Social and International Relations of Science held a conference on "Human Factors in Industry". At the first session, under the chairmanship of Sir Henry Tizard, president of the Association, Prof. R. E. Lane, Dr. C. L. Cope, Mr. H. C. Weston and Dr. T. Bedford spoke on the improvement of physical environmental conditions. At the second, under the chairmanship of Sir George Schuster, there were contributions by Dr. R. F. Tredgold, Mr. D. Chapman and Dr. A. T. M. Wilson on problems of human relations, and Mr. Alec Rodger summed up.

Prof. Lane, of Manchester, introduced by Sir Henry Tizard as the first holder of the first British chair of industrial medicine, dealt chiefly with the influence of environmental conditions on health, and in doing so stressed the value of the medical man's part in studying and improving them. He emphasized particularly the role of the industrial medical officer as an apostle of preventive medicine. In his view, a firm's occupational health should be the concern of a team led by the management, and representatives of various interests within the firm. The medical man could often help management to decide on the conflicting claims of experts inside the organisation. Prof. Lane indicated that training facilities, capable of producing men suitable for the educative and advisory work he had outlined, are now available. What was needed next was a guarantee from industry that there would be employment for the best type of medical officer. If that guarantee were given, the men would be provided.

Dr. Cope, director of research into human problems for the National Coal Board, confined his attention to the coal industry. As Dr. P. Hugh-Jones, a stimulating participant in the general discussion, put it, he spoke of darkness, danger and dust. Human wastage from accident and disease is greater among miners than among any other section of the industrial community. Deaths on the job average 550 a year, and accidents causing more than three days absence number 180,000 a year. Certifications of permanent incapacity from pneumokoniosis total 4,000 annually. The corresponding figures for nystagmus and dermatitis are 1,800 and 1,600. In addition, of course, the industry is afflicted with a multitude of wage disputes.

Vast changes are needed to remedy present bad conditions, and a start is being made. Ventilation is on the whole good, and lighting is improving. The number and efficiency of cap-lamps is rising steadily, and fluorescent lighting is being installed experimentally not only in haulage ways but also at the coal face. Attempts are being made to determine the effects of improved lighting on the incidence of nystagmus and accidents, and to facilitate the investigation of accidents a new system of accident recording, developed by Mr. J. W. Whitfield of the Cambridge Psychological Laboratory, has been largely adopted. In the effort to combat pneumokoniosis, dust suppression by spraying with water or foam is being tried extensively, and Dr. T. H. Jenkins is collecting data on the efficiency of these procedures. Dr. Cope indicated that improvements in working conditions at the coal face would probably come slowly, because the cost of making them has constantly to be balanced against the cost of coal to the consumer. He added that he did not wish it to be assumed that he regarded these improvements as more important than improvements in human relations.

Mr. Weston and Dr. Bedford, both of the Industrial Health Research Board, summarized the findings of the Board's investigations in the fields of lighting, heating and ventilation. In the course of his talk, which was delivered in Stygian conditions not conducive to satisfactory note-taking, Mr. Weston displayed a number of slides depicting good and bad lighting. Dr. Bedford gave the following six rules for the arrangement of pleasant and invigorating working conditions: (1) A room should be as cool as is compatible with comfort. (2) There should be adequate air movement but no local draughts. (3) The air movement should be variable rather than uniform and monotonous, for the body is stimulated by ceaseless change in the environment. (4) The relative humidity of the air should not be above 70 per cent and should preferably be much below that figure. (5) The average temperature of the walls and other solid surroundings should not be appreciably lower than that of the air and should preferably be higher. The combination of cold walls and warm air often causes feelings of stuffiness. (6) The air at head-level should not be distinctly warmer than that near the floor, and the heads of the occupants should not be exposed to excessive radiant heat.

In the discussion at the end of the first session of the conference, stress was laid on the need for operational research in the coal and cotton industries; and on the need for greater co-operation between medical scientists, engineers and others, not only for the improvement of environmental conditions but also for the improvement of the design and layout of machinery. Although all the main speakers had explicitly referred to the importance of psychological factors in the study of environmental conditions, it was evident that many members of their audience thought they had not made enough of this point.

Opening the second session, Sir George Schuster, chairman of the Industrial Productivity Committee's Panel on Human Factors, said that our aim must be to make industrial employment the basis of a satisfying life. The main problem is to discover how scientific workers can influence the conduct of industry at the present time and in its present mood. At what points should the man of science intervene? What methods should he use? In answering these questions, we must realize that conditions vary from one industry to another and from one place to another; the introduction of joint consultation to a coal-mine throws up difficulties different from those encountered in its introduction to a cotton-mill.

Dr. Tredgold, of the Roffey Park Rehabilitation Centre, maintained that 'human relations' is merely a new label for an old subject, but that, in fact, we know very little about human relations in industry. Particularly, we have not sufficiently recognized the need for social skill in those we call leaders: in selecting them, we have assumed that technical qualifications are enough, and we have given them very little training. To some extent, training is now being provided for junior leaders, but training for management is still inadequate. It is important for leaders to realize that very often people do not do what they should because they do not see *why* they should. If we want people to act in a certain way, we should take pains to see that they appreciate our reasons, and we should seek to understand their prejudices. In a passing comment on rehabilitation, Dr. Tredgold remarked that the aim at Roffey Park is not merely to encourage people to look after themselves, but also to encourage them to look after others.

Mr. Chapman, of the University of Liverpool, considered that the current tendency to exclude consideration of the pay-packet from discussions on incentives has gone too far. Financial incentives are undoubtedly important. At the present time, however, the proper use of them presents many difficulties; and we have yet to develop the social processes needed to secure the adoption, by management and workers, of modern payment systems. Suspicions based on their experience during periods of mass employment are still widespread among workers, many of whom doubt whether full employment will last. However, in the newer industries which make considerable use of semi-skilled and young workers, there is a more rational attitude than that commonly found in, for example, the cotton industry. Mr. Chapman remarked that in his view some of the unwillingness to produce additional effort was caused by the 'P.A.Y.E.' system of collection of income tax, which creates the impression that hard workers are penalized. He added that we must not overlook the fact that there is evidence that during the last thirty years national morale has declined considerably. Present culture patterns reflecting the decline include the popularity of football pools, self-medication, the building society movement and insurance-for-all.

Nation-wide exhortations have little or no effect; sometimes, Mr. Chapman said, they have a bad effect. The approach should be to the working group concerned, and the schemes proposed should not be elaborate. One firm has recently developed a simple piece-work scheme based on the advice of consultants who had said that output could be increased by a third. After persuading the local union organiser that the plan was not a capitalist plot, the firm tried it out in one small department. When the operatives in the department had accepted it, a team of people, including two workers, were asked to arrange for its extension to other departments. The scheme has so far been a great success. Elsewhere, a 'production drive' technique had been adopted. This was Saturnalian in character, for the trade unions had been persuaded to make substantial concessions for a fixed period. For example, young workers had been allowed to compete for prizes of up to 3 guineas. An increase in output of 75 per cent had been obtained by this method, and efficiency had become an important factor in prestige. A drawback of the scheme was its tendency to make mothers ask: "If Alice can get an extra pound this week, why not next?" Facile solutions, it must be recognized, have their dangers.

Dr. Wilson, of the Tavistock Institute of Human Relations, developed with emphasis Mr. Chapman's arguments about the importance of regarding the working group as a group. From birth onwards we are members of groups; our behaviour is greatly influenced by our membership of various groups; and our behaviour in one group is not the same as our behaviour in another group. The chief cause of low productivity often lies in bad group morale. We must therefore be ready to investigate factors affecting the morale of the group as a whole, and its constituent sub-groups, as well as factors affecting the morale of the individuals concerned. We cannot do this satisfactorily by conventional scientific procedures of observation and experiment. We must develop a close relationship with the group. This relationship must be more than a very friendly one; it must be therapeutic. In fact, only through a healing approach can diagnosis properly be effected.

If we pursue this aim by this method, what do we find? One of our discoveries will be that the workers in a group have spontaneous co-operative tendencies which are often denied expression. Another will be that there exists in industry (as outside it) an almost universal system of 'scapegoating'. This leads every group—management, line executives, technicians, office workers, supervisors, workers at the bench and on the shop floor—to find the causes of their own dissatisfactions in other groups. However, despite its tendency to blame other groups, every group has a 'need' for good relations with those others. For example, behind the envy which the shop worker feels for the clerk, there is often a real desire to work in a community in which hostility does not exist. Dr. Wilson concluded that, in fact, most groups have it in them to overcome their difficulties, and he pleaded for arrangements which would enable them to release their self-healing resources by free discussion and other means. This in turn led him to strong advocacy of the abandonment of autocratic practice and its replacement by honest co-operation.

In his summing-up, Mr. Alec Rodger, senior psychologist to the Admiralty, spoke critically of certain points made in the main contributions to the first session of the conference. He was in full agreement with most of Prof. Lane's remarks, but he disliked his suggestion that the industrial medical officer should become a kind of 'super'-adviser to management simply because he is a medical practitioner. If Prof. Lane could recruit doctors of the quality he wanted, he would, in fact, soon find them performing the duties he had planned for them; otherwise he would not, nor should he. Dr. Cope, Mr. Weston and Dr. Bedford had given convincing proof that in their particular fields much progress had been made, but it seemed to Mr. Rodger doubtful whether their findings are being utilized satisfactorily as the starting points for further researches. The American Hawthorne experiments had been used for this purpose: why could not ours? Mr. Rodger wanted to know whether, as a matter of routine, experiments on the influence of 'old' and 'new' environmental conditions were followed by investigations of the influence of what he called 'reinstated old' conditions. He thought they should be. In a comment on Dr. Wilson's address, with which he was in general sympathy, he challenged Dr. Wilson to explain why he and his colleagues are convinced that problems of human relations in industry cannot be studied by conventional scientific procedures.

Mr. Rodger urged, in conclusion, that we should recognize the present importance of short-term research in the industrial field; that we should readily participate in the co-ordination of our researches (by groups of recognized and accepted experts who would 'vet' research proposals and ask, about each, What problem is this meant to solve? How important is it that it *should* be solved? Is this the best way of solving it?); that with the aid of the statistician, who is indispensable in researches involving many variables, we should make more determined use of ordinary observational and experimental methods of inquiry; that we should learn to communicate our findings, in simple words and pictures, to everybody concerned (from politicians and senior Civil servants to workers on the shop-floor); that we should take pains to let people know what our functions are; that we should constantly strive to acquire more appreciation of the problems of the managers we advise; and that, above all, we should investigate thoroughly the causes of managerial and shop-floor resistance to techniques intended to increase production. He suggested that the British Association should later stage a conference with a broader sweep, at which a series of short progress reports might be read on 'fitting the man to the job' and 'fitting the job to the man'. Under the first heading might come work on the improvement of methods of vocational guidance, personnel selection, and occupational training. Under the second might come the improvement of methods of work, design and layout of working equipment, and working conditions (both physical and psychological).

SCIENTIFIC RADIO

A SPECIAL feature of the programme of the Radio Section of the Institution of Electrical Engineers this session was the holding of a Convention on Scientific Radio during April 7 and 8. This Convention, which was organised by the Institution in co-operation with the British National Committee for Scientific Radio, afforded an opportunity for a preliminary survey of the British contribution to be presented to the forthcoming meeting of the Union Radio Scientifique Internationale (U.R.S.I.), which has already been announced in *Nature* of May 1, p. 695. The proceedings of the Convention were divided into four sessions corresponding in scope to the four commissions of the Union Radio Scientifique Internationale; and in each session four or five short papers were presented surveying progress in the past few years in various parts of the field of fundamental radio science. Ample opportunity was provided for speakers who wished to discuss the individual contributions, and abstracts of the papers and of the discussions will in due course be published in the *Journal of the Institution.*

Standards and Measurements

The first session, on "Standards and Measurements", was held under the chairmanship of Mr. P. Good, president of the Institution of Electrical Engineers; and the four papers presented on this occasion emanated from the National Physical Laboratory (Department of Scientific and Industrial Research). The chairman explained that this was perhaps to be expected, since it is one of the duties of the Laboratory to set up and maintain tandards of reference for the electrical and radio measurements required by all users of the corresponding techniques. As was made quite clear by he individual speakers who followed, however, it was not intended to suggest that all progress made n recent years had been conducted within the Department of Scientific and Industrial Research; or it is well known that many substantial contributions during the war years were made by certain Government establishments and by industry.

Dr. L. Hartshorn, in a paper on "Radio Standards" resented jointly with Dr. L. Essen, first referred to the fact that, of the three standards recognized throughout the whole field of physical science, namely, length, mass and time, the last, if not already a radio standard, is very little short of it. For if once it is decided that the vibrations of the existing quartz-frequency standards are more regular than the rotation of the earth, then, for the period in question, the rotating earth is no longer to be regarded as the standard of either frequency or physical time. The paper pointed out the dependence of radio measurements on the existing electrical standards, and emphasized the need for distinguishing between definitive standards, derived standards, transfer standards and working standards. Reference was made to the changes which took place on January 1 last, when the ohm was defined by reference to the standards of length and time, with consequential changes in the numerical values of reactance and resistance of 0·05 per cent. Since inductance and capacitance standards can now be measured at radio frequencies with an accuracy of about 0·01 per cent, these changes are of decided significance in precision radio measurements. Frequency can be measured to a much higher order of accuracy, and an illustration was shown of relative measurements on three typical quartz standards, differing widely in design. These were found to agree with one another to within 2 or 3 parts in 10^8 over a period of several months.

In the following paper, Dr. T. I. Jones reviewed the techniques used in the measurement of current, voltage, impedance and attenuation at frequencies below about 300 Mc./s. Signal generators and receivers are calibrated in terms of voltage which, at a level of about 0·1 volt, can conveniently be measured by means of valve or crystal-detector voltmeters, and by a combination of a vacuum thermojunction and resistors in series or parallel. Suitable voltage-dividers are available to extend the range upwards and downwards. The methods available for measuring impedance fall into two classes: those which use resonance circuits and which are used for measuring components, cables and the properties of dielectrics; and bridge networks, which are available up to frequencies of the order of 50 Mc./s. but which deteriorate in performance for frequencies above 10 Mc./s.

Mr. F. M. Colebrook described the changes in technique which have taken place in recent years in conducting radio measurements at frequencies above about 300 Mc./s.; and some discussion ensued on the possibility of reaching agreement among workers interested on the value of this boundary frequency, above which current and voltage measurement should give place to the determination of power. The general position with regard to measuring technique at the very high frequencies now in common use remains substantially as has been described in various papers published in the *Journal of the Institution of Electrical Engineers* during the past two years.

The subject of radio field-strength measurement is of direct interest in connexion with all applications of radio-wave technique, and Dr. R. L. Smith-Rose presented a survey of the main lines of development of this subject over the past ten years or so. At the present time suitable field-strength measuring equipments have been developed on an experimental basis for all radio frequencies between about 0·1 and 600 Mc./s.; but there is a need for further development of these and for an inter-comparison of the different types available on both a national and an international basis.

Propagation

Sir Edward Appleton, secretary of the Department of Scientific and Industrial Research, presided at the next session, at which five papers were presented dealing with some topical aspects of the subject of radio wave propagation. Dr. A. C. B. Lovell gave an interesting account of his recent investigations on meteors, conducted by the aid of radar techniques at wave-lengths of a few metres and less. When a meteor enters the earth's atmosphere, it burns away at a height of about 100 km. and creates a dense concentration of electrons which scatter energy from incident radio waves. On a wave-length of about 4 m., the number of echoes which have been detected by available radio equipment is very closely related to visible meteoric phenomena. As the wave-length is increased, however, the rate at which echoes are detected undergoes a striking change, and at wave-lengths greater than 8 m. several hundred echoes per hour are received, a number which bears no close relation to the visible observations. The sporadic ionization in the *E*-layer of the ionosphere is now considered to be mainly caused by the effect of meteors, particularly in temperate latitudes.

In 1934 it was discovered that radio waves traversing the ionosphere could interact with each other in such a way that the modulation of one was transferred to the other. This effect was explained at the time by supposing that the absorption of energy from one of the waves increases the temperature of the electrons in the ionosphere, with a consequential increase in their collision frequency with neutral molecules. As a result, the absorption of the other wave is increased; and since this absorption varies with the modulation of the first wave, this modulation will be transferred to the second wave. Experimental work on this phenomenon has recently been resumed at the Cavendish Laboratory at Cambridge; and Mr. J. A. Ratcliffe described the manner in which he and his colleagues have been observing the phase of the transferred modulation, and comparing it with the phase of the modulation received direct, as a ground wave, from the interacting station. From the results of such measurements, it is possible to determine the collision frequency of the electrons at a known height; and the experiments have given values around 5×10^6/sec. for a height of about 85 km.

The third paper at this session was presented by Dr. W. J. G. Beynon, who gave an account of recent investigations on the reflexion of radio waves from the ionosphere at oblique incidence. He pointed out that it has long become established practice to calculate the maximum usable frequency for any desired transmission path from normal-incidence ionospheric data with an accuracy which is satisfactory for most practical purposes. Experiments on the absorption of radio waves carried out in Great Britain have shown that there is a marked disagreement between the apparent absorption at oblique incidence and that predicted on theoretical grounds from the values measured at normal incidence. In a similar manner, estimates of oblique-incidence ionospheric absorption obtained from observations of signal strength over trans-Atlantic radio circuits disagree with the values expected from long-term normal-incidence measurements. This subject of the absorption of radio waves in the different regions of the ionosphere is being actively pursued at the present time under the auspices of the Radio Research Board of the Department of Scientific and Industrial Research.

The need for increased knowledge on the propagation of very long radio waves has recently come into prominence due to the development during the War of some novel and very accurate methods of defining the position of a radio receiver, by measurements made on the arriving waves. Work on this subject was in progress at the Cavendish Laboratory before the War; and Mr. R. N. Bracewell gave an account of the experiments, which have now been resumed, on frequencies of 16 and between 30 and 40 kc./s., corresponding to wave-lengths of about 19,000 and 9,000 m. respectively. The height of reflexion of these very long waves is about 80 km., with regular diurnal variations, which are symmetrical about noon, of some 18 km. in summer and 12 km. in winter. Such measurements are made by determining the phase path of the sky wave received at distances of a few hundred kilometres, using the ground wave, which varies little with respect to the transmitter, as the source of reference.

Dr. H. G. Booker presented a new way of visualizing the Sommerfeld theory of propagation over a flat and imperfectly reflecting earth. This theory arose because the ray theory involves the assumption that the Fresnel reflexion coefficient of the earth does not vary rapidly with angle of incidence, and this assumption is not satisfied for vertically polarized medium waves as used for broadcasting, arriving at the earth's surface at glancing incidence. The main object of the new presentation is to facilitate the solution of problems involving propagation near the surface of the earth partly over land and partly over sea, a condition which applies frequently in practice to radio transmission for communication and other purposes.

Radio Noise

At the third session, on "Radio Noise", the chair was taken by Sir Robert Watson-Watt, who is chairman of the British National Committee for Scientific Radio. In a paper entitled "A Survey of Recent Progress in the Study of Fluctuation Noise", Dr. D. K. C. MacDonald referred to the report made by the Union Radio Scientifique Internationale on this subject in 1946, and to the subsequent publication of the associated work primarily directed to war requirements, which was concerned broadly with noise at frequencies of 60, 600 and from 3,000 to 10,000 Mc./s. The main problems have been in the development of methods and instruments for noise measurements, of valves, circuits and crystal detectors to improve the ratio of signal to noise. It is well established that certain elements show increased noise at relatively low frequencies; and a study of this phenomenon, which includes 'flicker effect' in valves and 'current noise' in semi-conductors, is of considerable significance, for example, in the design of amplifiers for the study of physiological effects.

During the past few years, there has been a marked resumption of interest in 'atmospherics', a subjec which had hitherto been rather neglected by radio physicists for some ten years. Two papers presented to the Convention served to direct attention to th investigations now in progress. In the first of these Dr. T. W. Wormell and Mr. E. T. Pierce described some recent studies made at the Solar Physic Observatory, Cambridge, on the structure of th disturbances in the vertical electric field at the earth's surface resulting from lightning discharges

In one type of investigation cathode-ray tube equipment and photographic recording technique are used to investigate the variation with time of the electric field produced by discharges not more than 50 km. distant. Concurrently, an investigation is being made of the detailed wave-form of the disturbance due to radiation from discharges at distances of many hundreds of kilometres. The results of such observations were discussed with the aid of photographic records and diagrams.

In the second paper, Dr. H. A. Thomas, of the National Physical Laboratory, described some of the results obtained from an analysis of observations of the strength of atmospherics as measured at some fourteen stations in various parts of the world. A large number of slides were shown to illustrate the general trend of these observations, which were made on five frequencies between 2·5 and 20 Mc./s., in which band the propagation of radio waves through the ionosphere is likely to play an important part in determining the general strength of atmospheric noise at any place. One of the important conclusions from this study, however, is that the characteristics of the atmospheric noise observed at any one location do not appear to be applicable over any large area; and this would tend to indicate that the sources of the noise being measured are local to the observer. Large differences between the ratio of day and night values are observed at different places; seasonal effects are marked, and also differ appreciably with location. Far more data on this subject are required, however, before any very definite conclusions can be drawn on such a complex subject.

The remaining two papers in this session dealt with recent investigations of the characteristics of galactic and solar radiation. Mr. J. S. Hey described how the emission of high-intensity radio waves from sunspot regions was first established by observations made with Army radar receivers in February 1942, during the transit of a large and active spot across the sun's disk. In the intervening years many workers have made observations of this phenomenon, particularly during the recent maximum of the sunspot cycle. The intensity of the radiations observed is particularly strong for a wave-length around 5 metres, and falls off very considerably as the wave-length is reduced below 1 m. Corresponding reception of this type of radio noise, as first noted by Jansky in 1932, has also been studied by recent workers; and in the discussion of this paper, Dr. J. L. Pawsey described some interesting observations, made in Australia, on galactic noise, from which it appears that some of the stars, or combinations thereof, radiate much more strongly than sunspots. This was followed up by Mr. M. Ryle's paper, describing experiments made on radiation emitted by the sun on wave-lengths of 1·7 and 3·8 m. The observations have been continued over a period of fifteen months, and it has been found that in the absence of sunspots the sun radiates with an intensity corresponding to a surface temperature of 10^6 °K. The radiation from sunspots is characterized by sudden increases of intensity which correspond to much higher temperatures.

Radio Physics

At the fourth session of the Convention, on "Radio Physics", the chair was taken by Prof. G. I. Finch, president of the Physical Society. The papers presented at this session demonstrated the manner in which some physicists are using the very high-frequency radio techniques, corresponding to wave-lengths of a few centimetres and less, to study various properties of solids, liquids and gases. Dr. B. Bleaney described the use of centimetre waves for studying absorption lines in the spectrum of gases due to heavy polar molecules. By making the radio frequency measurements to a high order of accuracy, the broadening of the lines due to collisions has been investigated at pressures up to six atmospheres. At low pressures (0·1–10 cm. mercury), the widths of the lines vary directly with the pressure; while at pressures above one atmosphere, the line breadth ceases to rise as rapidly as the pressure. Among the most interesting spectra studied in this manner are those of ammonia and water-vapour, the latter being of particular importance as a constituent of the atmosphere.

In their paper on "High-Frequency Absorption Phenomena in Liquids and Solids", Prof. Willis Jackson and Dr. J. A. Saxton directed attention to the significance of investigations on such materials as polythene, which is substantially non-polar, and liquid water, which exhibits purely polar characteristics. Such centimetre-wave measurements have served to illustrate more convincingly than previous work at longer wave-lengths the limitations of the original dipole theory of dielectric absorption formulated by Debye. With the reasonable prospects now in view of the extension of the range of these measurements to the millimetre wave-band and so towards the far infra-red portion of the spectrum, such investigations present interesting possibilities of leading to a fuller understanding of the properties of the liquid and solid states. In the meantime, the data already acquired on the absorption and scattering effects of water, ice and water vapour are of great value in connexion with the use of centimetre wave transmission through the atmosphere, and with the effect of fog, clouds, rain and snow on such transmission.

In the course of another paper in this session, Drs. R. Cooper and W. A. Prowse described experimental determinations of the minimum electric breakdown stress in air at frequencies corresponding to centimetre wave-lengths. It was found that radioactive irradiation of the spark gap improved the precision of the measurements without affecting the deductions drawn from the results. Spectrographic observations were made of the spark itself, and of the accompanying bright spot on the electrodes.

A paper entitled "Investigations of Magnetic Phenomena at Centimetre Wave-lengths" was presented by Dr. J. H. E. Griffiths, of the Clarendon Laboratory, Oxford, in which he stated that it is only recently that it has been possible to make measurements on the permeability of ferromagnetic materials in the centimetre wave region, and these have led to some interesting results. In addition to studying the permeability, which decreases rapidly with increase of frequency, the effect of a superimposed steady, transverse magnetic field has been investigated. It is then found that ferromagnetic metals exhibit a resonance phenomenon, in that the high-frequency loss in the metal becomes a maximum for a certain value of the steady magnetic field. A number of paramagnetic salts show a similar resonance absorption, and the interpretation of the results of such measurements is leading to a better understanding of the magnetic properties exhibited by various substances.

The last paper in the session, and also of the Convention, was presented by Mr. A. B. Pippard, who described experiments on the high-frequency conductivity of metals at low temperatures. It is well known that the classical theory, supported by measurements at moderately high frequencies, indicates that the resistivity of a conductor as determined by the skin effect should be inversely proportional to the square root of the bulk conductivity. Experiments made at a frequency of 1,200 Mc./s. have shown, however, that while this is true at room temperature, the great increase in conductivity due to cooling pure metals to very low temperatures is not accompanied by a corresponding decrease of surface resistivity. The explanation of this effect is that the free paths of the conduction electrons at low temperatures may exceed the classical value of the skin depth by as much as a factor of 100 under the conditions of the experiments. Thus it is no longer permissible to assume the validity of Ohm's law, since only a small proportion of the relevant electrons contribute to the surface conductivity. It is clear that we have here a quantitative radio technique for exploring the free paths of electrons, and investigations were referred to in which the method is being applied to the study of the surface characteristics of pure metals.

In the course of the discussion, Dr. R. A. Smith very aptly referred to the interesting fact that physicists, who had so ably assisted the radio investigators in the development and exploitation of radar and communications during the War, have now taken back into their own research laboratories some of the problems exposed by the radio engineers. The development of the higher frequency radio techniques in the past few years has clearly provided powerful research tools for studying the general physical constitution of matter. R. L. SMITH-ROSE

PROBLEMS OF TIDAL BIOLOGY

IN a letter published in *Nature* in 1944 (**154**, 300) it was pointed out by Prof. T. A. Stephenson, of University College, Aberystwyth (in continuation of an argument initiated by Prof. F. E. Fritsch, *Nature*, **154**, 144; 1944), that future investigation of intertidal biology in Great Britain demanded: (*a*) further work on the British coasts between tide-marks; (*b*) further work on the continental shelf of the British region below tide-marks; and (*c*) an attempt to make a preliminary world statement, based on a carefully selected series of surveys made by the same workers.

Since 1944 progress has been made towards the realization of all these objectives, but the present article is concerned particularly with the third one. Prof. Stephenson has now undertaken to write a monograph on plant- and animal-life between tide-marks throughout the world, and the expedition described below was a step in that direction. The monograph is intended to supplement the well-known works of Ekman ("Tiergeographie des Meeres", 1935) and of Sverdrup, Johnson and Fleming ("The Oceans", 1942). These volumes both provide world-wide pictures of certain aspects of marine life, but neither devotes particular attention to the intertidal region; nor is there any general work which attempts to do this. In the task which he has undertaken, Prof. Stephenson will have behind him thirty years experience of ecological work between tide-marks carried out in Australia, South and East Africa, Mauritius and Great Britain, much of which is embodied in a series of admirable papers. The shores of North America have now been added to the regions studied by him. In much of this work, of a type which could not be conducted unaided, Prof. Stephenson has been assisted by collaborators, and throughout Mrs. Stephenson has acted as his technical assistant.

Between December 1946 and January 1948, Prof. and Mrs. Stephenson made a thirteen months visit to the United States and Canada to collect new material for their monograph. It has been recognized throughout that, while nobody can expect to visit all the coasts of the world in this connexion, there is a certain amount of uniformity between one coast and another within the same temperature limits. There is thus reason to expect that a judiciously chosen series of samples will provide a basis for a general statement which, if only a first approximation, will form a foundation for later work. It so happens that most of the samples needed to complete Prof. and Mrs. Stephenson's earlier experience are to be found in North America. On this ground their visit was supported either financially or by the provision of facilities, or both, by a number of institutions in Great Britain and America.

While the intertidal ecology of the North American coasts is much better known than that of South America, it has been investigated less than might be supposed. There is an extensive literature dealing with the systematics of intertidal plants and animals, and a very considerable amount which describes the biology of particular species. Contributions reviewing the shore ecology as a whole are much fewer, and where they exist, may deal primarily with animals (for example, Hewatt[1]) or with plants (for example, Doty[2]) and rarely cover wide areas, except in occasional works such as that of Ricketts and Calvin[3], and the paper by Doty already mentioned. There are vast stretches of the coast which remain almost unknown from an ecological point of view. The places visited during the present work were chosen, so far as possible, in areas where the general shore ecology has not been described. The summary which follows is derived from a privately printed report prepared for submission to the institutions which supported the work.

The time spent in America extended from January 1, 1947, to January 25, 1948. During this period a distance of some 15,000 miles was covered, mainly by motor-car, and shore-work was carried out first on the Atlantic coast—among the Florida Keys, at Marineland in North Florida, at Charleston in South Carolina and at Beaufort in North Carolina. After crossing the continent it was continued on the Pacific coast at Nanaimo in British Columbia, and afterwards at Pacific Grove and La Jolla in California. This schedule permitted a stay of approximately two months at each of the main centres.

The amount of information collected was considerable, and it will be some time before it can be worked up for detailed publication. Meanwhile the following note will indicate the nature of the results. The work falls roughly under three headings: (*a*) broad geographical aspects; (*b*) questions of vertical and horizontal distribution within small areas; and (*c*) the causes of the facts observed under (*a*) and (*b*).

The Florida Keys represent a tropical region with an abnormally scanty intertidal population; scanty, that is to say, in total bulk of organic material regarded as a crop, not in number of species represented. The latter is considerable. The environmental features with which this poverty is connected appear to be produced by a peculiarly shallow, very heavily sedimented sea, with a low concentration of nutrient salts, operating in a tropical region with a rather small tidal range, on a clinker-like substratum formed from dead coral. This situation will be described for the first time, and it is hoped that a comparison of so unusual a tropical area with more ordinary ones will yield information about the underlying reasons for the differences.

The coasts of northern Florida, together with those of North and South Carolina, present an entirely different picture. It is hoped to show that between Cape Hatteras and Cape Canaveral there lies a region inhabited by a warm-temperate tidal biota with distinctive features of its own. The coast here consists primarily of sand, mud and gravel, outcrops of material harder than peat being exceptional; but the lack of hard substrata is made up for, to some extent, by the existence of rough rocky breakwaters essentially similar to reefs of natural rock. Information has been obtained relating to the reaction of a warm-temperate population of seaweeds and animals to the presence of small areas of hard bottom lost among vast tracts of sand, and it is expected that this will prove to be useful material for a general discussion of the problems of intertidal life.

On the Pacific coast, the areas visited provide the following special features. At Nanaimo in British Columbia there flourishes a superb example of a rich, fully marine fauna, in a region of quiet creeks with reduced wave-action, in a low range of salinity (23–28 $^{0}/_{00}$). It is remarkable in itself that so large a population of stenohaline animals such as starfish and anemones should flourish in water of such low salinity; but the district offers also, in the form of Brandon Island, a small island with a gradual, sunny, southward slope and a precipitous, shady, northern cliff, a perfect demonstration of the effect on plant and animal distribution of the contrast between these two combinations of conditions. Other reefs and islands in the district supplement what Brandon Island supplies, and also offer contrasts. Around the Monterey Peninsula and Point Lobos in California, on the other hand, there is found an example of a more southern version of a population not unlike that of Nanaimo, but exposed (on the more wave-beaten promontories) to maximal oceanic wave-action. In spite of the powerful wave-action, however, the very rugged and irregular nature of the coast provides so many degrees of exposure to, and shelter from, wave-action in small areas that the effect of these differences on a rich marine population in an area of normal salinity can be studied to advantage. Lastly, in the neighbourhood of La Jolla, near the boundary between Mexico and California, another very different picture is encountered. The wave action, while considerable and oceanic, is moderate compared with that of the Monterey region; and the shore biota is of a warm-temperate type, distinctly different ecologically from that of the more northern stations. The rock along the shore, moreover, provides a remarkable demonstration of the effect of different degrees of hardness on the species which can colonize it. The most prevalent rock is so soft that it has specific unusual effects on common organisms such as barnacles and encrusting Corallinaceæ; and these effects can be checked by comparison with local areas in which the rock is harder, in varying degrees, than the average, and which show clearly what happens on hard rock as compared with soft in the same district.

Throughout the work special attention has been paid to the zonation of plants and animals between tide-marks, and the relationship between zones and tide-levels will figure largely in the results. During their previous work in South Africa (see *Nature*, **143**, 503; 1939; and **156**, 27; 1945) Prof. and Mrs. Stephenson developed the idea that the shore zonation found there is based on a plan of universal application. They were able to test this idea later in Great Britain, Mauritius and East Africa, but during 1947–48 tested it much more widely on a variety of American shores. So far it has stood this examination very well, but there is much work to be done before the detailed application can be made.

The regional peculiarities of different parts of the world reveal themselves in many ways. This is shown particularly well by the distribution of limpets, which is one of the subjects covered in this work. While limpets of some kind are peculiarly characteristic of the intertidal regions of the world, the *genera to which they belong* show a markedly regional occurrence. Thus, in some areas the leading limpet genus is *Patella*; in others *Acmæa*; and on many of the warmer shores the pulmonate *Siphonaria*. An interesting point brought out by the present study is that the Carolina coasts visited are most exceptional in that, to all appearance, they have *no limpets at all* on open rock surfaces.

The prime object of the work here summarized was not the amassing of facts as such but their comparative study with the view of elucidating the underlying fundamental principles which are responsible for the surface appearances described. These principles cannot, however, be formulated until a full examination of the facts has been made. In the course of this expedition Prof. and Mrs. Stephenson have added greatly to their already unique experience in the study of shore ecology. It is most sincerely to be hoped that nothing will prevent, indeed that circumstances will conspire to further, the production of the monograph to the completion of which on the broadest possible basis their labours are directed.

OBITUARIES

Prof. G. H. Hardy, F.R.S.

GODFREY HAROLD HARDY, who died at Cambridge on December 1, 1947, was the creator of the English school of mathematical analysis and had been for more than a quarter of a century the leader of pure mathematicians in Great Britain. He was born on February 7, 1877, the son of Isaac Hardy, who was bursar and art master at Cranleigh School. He went to Winchester and, in 1896, as a scholar to Trinity College, Cambridge. He was fourth wrangler in 1898 and was placed in the first division of the first class in Part II of the Mathematical Tripos in 1900. He was elected a fellow of Trinity in 1900 and (together with Jeans) gained a Smith's Prize in 1901.

At the turn of the century, pure mathematics in Britain was at a low ebb. Since the days of Newton, mathematics had been regarded as ancillary to physics, and the achievements and prestige of Maxwell, Kelvin and Stokes had prolonged this attitude throughout the nineteenth century. There had been great pure mathematicians (such as Cayley), but they had worked in isolation and had been untouched by the movements in France and Germany.

In "A Mathematician's Apology" (1941), Hardy recounts his introduction to analysis—"My eyes were first opened by Prof. Love, who taught me for a few terms and gave me my first serious conception of analysis. But the great debt which I owe to him—he was, after all, primarily an applied mathematician—was his advice to read Jordan's famous 'Cours d'Analyse'; and I shall never forget the astonishment with which I read that remarkable work, the first inspiration for so many mathematicians of my generation, and learnt for the first time as I read it what mathematics really meant."

From 1900 until 1911 Hardy wrote many papers on the convergence of series and integrals and allied topics. Important as these researches are—they led to his election to the Royal Society in 1910—they are not his great work, and perhaps the most significant product of the early period was "A Course of Pure Mathematics". In this book Hardy expounded the basic ideas of analysis—limit, continuity, convergence—to the schoolboy of scholarship standard and the undergraduate. These ideas were so little appreciated that Hardy could then write (1908): "I have indeed in an examination asked a dozen candidates, including several future Senior Wranglers, to sum the series $1 + x + x^2 + \ldots$, and not received a single answer that was not practically worthless—and this from men quite capable of solving difficult problems connected with the curvature and torsion of twisted curves".

In revising the book for the seventh edition (1938), he could reflect that, if he were to rewrite it, it would no longer be necessary to write like "a missionary talking to cannibals".

About 1911 came the real crisis of Hardy's career when he began his long collaboration with J. E. Littlewood, a partnership without parallel in the history of mathematics. One problem after another was reduced by the powerful methods which they developed, and on some topics in analysis there now seems nothing more to be said. The main headings of the joint work of Hardy and Littlewood are convergence and summability of series, trigonometrical series, inequalities and the analytic theory of numbers.

Their most spectacular work was in the theory of numbers; there are problems which need only elementary arithmetic for their statement (for example, "Is every even number the sum of two prime numbers?"), but all the resources of analysis are required to make any impression on them. Some questions (including the one quoted) are still unanswered, but they are not now—as they were in 1910—unapproachable.

In 1914 began another collaboration, this time with a man whose gifts were much less like Hardy's own than are Littlewood's. A poor, self-taught Indian, Ramanujan, wrote to Hardy stating a number of formulæ that he had discovered. He was brought to England and before his death at the age of thirty-two in 1920 had become a fellow of Trinity and a fellow of the Royal Society. Hardy's association with Ramanujan was in some measure that of teacher and pupil; he had to teach Ramanujan much of the routine analysis which every Tripos candidate now knows, and this without impairing the native genius of the man. Their joint papers are few, but one of them contains a theorem so astonishing that one cannot help indicating it.

Denote by $p(n)$ the number of ways of expressing the positive integer n as the sum of integers. For example, 5 can be expressed as $1 + 1 + 1 + 1 + 1$ or $1 + 1 + 1 + 2$ or $1 + 2 + 2$ or $1 + 1 + 3$ or $2 + 3$ or $1 + 4$ or 5, and so $p(5) = 7$. It is plain that $p(n)$ increases rapidly with n; and $p(200) = 3972999029388$ (as was shown by a computation which took more than a month). Hardy and Ramanujan's achievement was to establish an explicit formula for $p(n)$, of which the leading term is

$$\frac{1}{2\pi\sqrt{2}}\,\frac{d}{dn}\,\frac{\exp\left\{\dfrac{2\pi}{\sqrt{6}}\sqrt{\left(n-\dfrac{1}{24}\right)}\right\}}{\sqrt{\left(n-\dfrac{1}{24}\right)}}.$$

Five terms of the formula give the correct value of $p(200)$.

Hardy was a lecturer at Trinity until 1919, when he became Savilian professor of geometry at Oxford; there he founded a flourishing school of research. For the year 1928–29 he went to Princeton, changing places with O. Veblen. He returned to Cambridge in 1931, succeeding E. W. Hobson as Sadleirian professor of pure mathematics; he held this chair until his retirement in 1942.

Hardy received degrees and honours from many universities and societies. He valued highly his honorary fellowship of New College, Oxford. During the last few weeks of his life he had pleasure in the award of the Royal Society's highest honour, the Copley Medal; he had already received a Royal Medal in 1920 and the Sylvester Medal in 1940.

In the course of his life, Hardy collaborated with many mathematicians besides Littlewood and Ramanujan; among others, with Titchmarsh, Ingham, Pólya, Wright, Rogosinski and M. Riesz. He had an exceptional gift for working with others, as he had for leading young men in their early days of research.

Hardy had one ruling passion—mathematics. Apart from that his main interest was in ball-games, of which he was a skilled player and an expert critic. An illustration of some of his interests and antipathies is given by this list of "six New-Year wishes" which he sent on a postcard to a friend (in the 1920's): (1) prove the Riemann hypothesis; (2) make 211 not out in the fourth innings of the last Test Match at the Oval; (3) find an argument for the non-existence of God which shall convince the general public; (4) be the first man at the top of Mount Everest; (5) be proclaimed the first president of the U.S.S.R. of Great Britain and Germany; (6) murder Mussolini.

It is fairly expected of a writer of a notice that he will, within the limitations imposed by language, attempt to portray his subject. How far would it be possible to describe Hardy, say to a mathematician of a new generation? His writings would attest both his power as a mathematician and his mastery of English prose. A picture might show his finely cut features and his physical grace. But no words can convey his liveliness and charm, which made a lasting impression on men even after one chance meeting, and which will remain fresh in the memory of those, mathematicians and others, among whom he lived.

Dr. Thomas Stephenson

The death of the Rev. Dr. T. Stephenson, at Hindhead on April 15, removed yet another of that band of amateur botanists (others were Mr. H. W. Pugsley, Col. M. J. Godfery and Mr. P. M. Hall) who did so much during the past thirty years to advance our knowledge of British orchids. Born at Brackley in Northamptonshire in 1865, Dr. Stephenson was a minister of the Methodist Church for many years until his retirement in 1934. The continual change of residence involved in his calling brought him into many parts of Britain and enabled him to study his favourite group of plants in a great range of conditions and habitats. He concentrated especially on the marsh and spotted orchids (*Orchis*, section *Dactylorchis*) and on the helleborines (*Epipactis*), both extremely difficult and little-understood groups. In a series of more than twenty papers published during the period 1918–42, many of which were written in collaboration with his son, Prof. T. A. Stephenson, or with Col. M. J. Godfery, he contributed materially towards the elucidation and clarification of these two genera. His outstanding contribution was the recognition and description of *Orchis purpurella*, now known to be one of the most widespread marsh orchids of Britain.

Dr. Stephenson did not restrict his work on orchids to England but, with the assistance of grants from the Royal Society, made special trips to France, Spain and Algeria, where he was enabled to study not only the British species but also their western European allies.

In his later years, when resident in Torquay, he helped to edit the first part of the "Flora of Devon", which appeared in 1939, and to which he contributed the part on Orchidaceæ. His interest was, however, not confined to these plants, and he was preparing an account of the mosses for the second part of the "Flora" just prior to his death.

V. S. Summerhayes

We regret to announce the following deaths :

Dr. A. S. Corbet, of the Department of Entomology of the British Museum (Natural History), on May 16, aged fifty-one.

Sir Daniel Richmond, C.I.E., during 1927–32 chief conservator of forests, Madras, on May 1, aged sixty-nine.

Prof. Väinö Tanner, known for his geological studies of the Fennoscandian region, on April 26, aged sixty-seven.

NEWS and VIEWS

"Proposed Central Publication of Scientific Papers"

Prof. J. D. Bernal writes: "In their letter published in *Nature* of May 15, the President and Secretary of Society for Freedom in Science put forward a number of reasons for rejecting the proposals for central distribution of scientific papers as set forward in my paper for the Royal Society Scientific Information Conference. The paper referred to, however, has not been published as it was intended for discussion in the first place and it is therefore impossible for most readers to judge how far it is open to the criticisms here given to it.

"Many of these do not apply to the proposals at all; others only to an interpretation of them which was certainly not the author's. Nearly all could be met by useful though inessential modification of the scheme. Thus there has been no proposal to abolish either journals, editors, or to curtail in any way their admirable functions.

"Although it would be possible to deal with these points in detail I feel that it would be preferable to leave discussion of them until the Conference where new statistical and technical material bearing on methods of publication and distribution will be available and where scientific societies will be fully represented. The scheme in question is only one of those before the Conference and is susceptible to modification and improvement. In any case the Conference can only indicate the direction in which changes in publication might be effected. The actual changes might be effected in an orderly way preceding each step by observation through operational research and voluntary experiment in a limited field. Any alterations would have to be negotiated with Societies and there is therefore little danger that the freedom of science will be interfered with."

Copies of Prof. Bernal's memorandum have been circulated to official delegates. In his memorandum Prof. Bernal states that: "More detailed descriptions of the steps which have led to the formulation of such a scheme are to be found in *Nature*, vol. 160, p. 649, 8 November, 1947, and the Report of Proceedings of the Twentieth Conference, 1945—Association of Special Libraries and Information Bureaux".

Dr. John Hutchinson, F.R.S.

The retirement of Dr. John Hutchinson from the scientific staff of the Royal Botanic Gardens, Kew, on May 31, after forty-four years service, will be noted with interest by botanists in many parts of the world. Hutchinson's early life was spent in handling and working with living plants in various horticultural establishments, and he started his career at Kew on the Gardens' staff in 1904. He showed such marked capacity for systematic botanical work that after less than a year he was transferred to the Herbarium. Here he was engaged in systematic and taxonomic work under Dr. Otto Stapf, with whom he worked for many years in the closest harmony. He was 'Assistant' for India for six years, and 'Assistant' for tropical Africa for a similar period. It was then that his special interest in African botany developed, and he was placed in charge of the African section of the Herbarium in 1922. He was responsible for some of the difficult groups (Euphorbiaceæ, Moraceæ, etc.) in the "Flora of Tropical Africa", and later, in collaboration with the late Dr. J. M. Dalziel, for the whole of the "Flora of West Tropical Africa". Hutchinson's knowledge of African plants was enhanced by two extensive botanical expeditions in southern Africa between 1928 and 1930, and by a visit to West Africa in 1937. On the first of these expeditions he visited the greater part of the Union, including Namaqualand, and travelled with General Smuts in the Zoutpansberg. The second expedition was made at General Smuts' express invitation; on this occasion they explored widely through Southern and Northern Rhodesia, Nyasaland and Tanganyika. The results of these journeys were described by Hutchinson in his attractive book, "A Botanist in Southern Africa" (Gawthorn, 1946).

In 1936 Hutchinson was appointed keeper of museums at Kew. He received the honorary degree of LL.D. from the University of St. Andrews in 1934, and in 1947 was made a fellow of the Royal Society in recognition of his services to science in the field of plant classification. His "Families of Flowering Plants" (2 vols.) has become a standard work. In the horticultural field his special interest for many years was the genus *Rhododendron* and later the genus *Sorbus*. He has received various horticultural honours, including the Victoria Medal of Honour of the Royal Horticultural Society. In his retirement Dr. Hutchinson hopes to complete a revision of Bentham and Hooker's "Genera Plantarum" and also some botanical works of a more popular kind. The good wishes of all his friends go with him.

American Awards for Work on Penicillin

THE United States Medal for Merit, the highest award made by the President of the United States to a civilian, has been presented to Sir Alexander Fleming and also to Sir Howard Florey for their work on penicillin. The citations accompanying the awards are as follow:

Sir Alexander Fleming, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations during 1939–45. Sir Alexander has distinguished himself and benefited mankind through his fundamental researches and exceptional scientific contributions on the therapeutic use of penicillin, which were of major importance to the successful completion of the mission of the medical services in World War II. His personal and enthusiastic assistance to medical officers in the European Theatre of Operations greatly advanced the earlier application of the penicillin programme than would otherwise have been possible in that theatre, thereby contributing materially to the care of the sick and wounded soldiers and to the conservation of man-power. Penicillin was a significant factor in halving the death-rate from wounds of United States troops in World War II as compared with those of World War I. Thousands of soldiers are alive to-day, and other thousands have been spared crippling disabilities, because of Sir Alexander's monumental contributions on penicillin.

Sir Howard Florey, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations during 1939–45. Sir Howard distinguished himself during this period through important contributions and fundamental researches in the development of penicillin. His foresight in conferring with United States scientists of the National Research Council in June 1941 greatly furthered the knowledge of this antibiotic agent and its potentialities, and made possible the large-scale production of penicillin, for the incalculable benefit of the sick and wounded. His vigorous leadership in the researches and utilization of this agent stimulated medical scientists to greater effort and greatly extended the field of usefulness of penicillin. His enthusiastic personal assistance to medical officers in the European Theatre of Operations was of utmost importance in providing penicillin therapy for sick and wounded troops in that theatre at an earlier date than would otherwise have been possible. The significant role of penicillin as a major factor in reducing deaths from wounds is apparent, for the rate was halved over the death-rate of World War I. Thousands of soldiers are now alive and other thousands have been spared crippling injuries because of Sir Howard's leadership in the development and utilization of this antibiotic agent.

Guthrie Lecture of the Physical Society

THE Guthrie Lecture of the Physical Society will be given this year by Sir George Thomson, his subject being "The Growth of Crystals". The Lecture will be given on June 4 at the Science Museum, London, S.W.7, at 5 p.m. During the First World War, Prof. Thomson made notable contributions to aerodynamics; later his attention was directed to the demonstration of the wave nature of the electron and the proof of de Broglie's Law. These experiments, now classical, earned him the Nobel Prize in 1937. After his appointment to the chair of physics at the Imperial College of Science and Technology, the work on electron diffraction in particular was continued and led naturally to an interest in surface layers and to the general question of crystal structure. During the Second World War, Sir George Thomson held a number of important Government posts and more recently was the British delegate to the Atomic Energy Commission of the United Nations Organisation.

Inter-Departmental Committee on Overseas Scientific Relations

THE Lord President of the Council, on the advice of the Advisory Council on Scientific Policy, has approved the setting-up of an Inter-departmental Committee on Overseas Scientific Relations to consider and advise on questions of United Kingdom Government policy on matters of overseas scientific relations. Sir Edward Appleton is chairman, and in addition to representatives of Government departments, the membership will include the foreign secretary of the Royal Society, representatives of the British Council and of the Conference of Research Associations, and two university men of science. The secretary of the Committee is Mr. H. L. Verry, head of the Overseas Liaison Division, Department of Scientific and Industrial Research, 142 Piccadilly, London, W.1.

Scientific and Industrial Research in Palestine

THE Government of Palestine Board for Scientific and Industrial Research, which is the successor of the Scientific Advisory Committee of the Palestine War Supply Board formed in 1942, has issued a "Report of Activities, April 1945–March 1948" accompanied by summaries of research and a list of publications of the Board (Jerusalem: P.O. Box 607 and the Hebrew University. Pp. 56. 150 mils.; 3*s*.) A list of standing advisory committees and subcommittees and their personnel is included, as wel as of the projects carried out during 1946–48 and the institutions in which the research was located Most of the investigations are being published in scientific periodicals, but full reports of all of them are available on request at the Office of the Board The Sub-Committee for Citrus Products has compiled a card index of scientific literature on citrus product to serve as a reference work for further research The index covers the period 1927–46 and will be published in book form. The Sub-Committee for Water Research has dealt mainly with physico-chemical aspects of the problems, and a literature survey on the influence of ions on plants and soils has been published. Dr. M. Reiner, while studying methods of testing asphalt and bitumen used at the Road Research Laboratory in Britain, commenced investigations which led to the discovery of an important phenomenon in the deformation of asphalt, and visited England again in 1947 to follow up this discovery. A summary of his report on the rheological properties of bitumen and asphalt is included among the research summaries, as well as a joint note with A. Arnstein and M. Teinowitz on the loading test of reinforced concrete structures. Other research reports deal with bovine leptospirosis, the chemical composition of fodder plants in Palestine, chemical composition and nutritive value of foodstuffs produced in Palestine, citrus products, thermostable thromboplastin from human placenta, metabolic disturbance in diabetes, work hardening of polycrystalline metals, and several chemical investigations.

Royal Photographic Society's Annual Exhibition

THE Royal Photographic Society's ninety-third annual exhibition is to be held at the Society's House at 16 Princes Gate, London, S.W.7, during September and October this year. It will be in two parts, the first devoted to pictorial and colour photography and the second to scientific, technical, Nature and record photography. Lantern slides, colour transparencies and stereoscopic exhibits will be on view throughout the whole exhibition. The Scientific and Technical Group of the Society is very anxious to make the second part of the exhibition fully representative of the best work in all branches of modern applied photography. It may not be sufficiently widely known that the exhibition is open to all users of photography, and can assist them by giving them a standard against which to judge their own work. The Scientific Section of the exhibition is divided, for convenience, into seven classes: photomicrographs; radiographs (medical and industrial being judged separately); astronomical and meteorological; geological and metallurgical; survey (aerial and terrestrial); medical and surgical; other scientific photographs. Nature photography, record and technical photography (architectural, press, commercial and advertising) and kinematography are in separate sections. Scientific and technical films should be entered in the last section. Photographs produced in the course of scientific research are particularly welcomed.

Two awards are made annually by the Society in the Scientific Section, namely, the Hood Medal for meritorious performance in any branch of practical photography, and the Rodman Medal for outstanding work, preferably in photomicrography or radiography. The closing date for receiving entries is July 24.

American Section of the International Union of Crystallography

THE U.S. National Research Council has appointed a group of leading chemists, physicists and mineralogists to act as provisional executive committee of the American Section of the International Union of Crystallography, which will hold its first general assembly and congress at Harvard University during July 28–August 3. The Committee consists of Prof. L. O. Brockway, University of Michigan; Prof. M. J. Buerger, Massachusetts Institute of Technology; Prof. J. D. H. Donnay, Johns Hopkins University; Prof. I. Fankuchen, Polytechnic Institute of Brooklyn; Prof. C. Frondel, Harvard University; Dr. D. Harker, General Electric Co.; Dr. M. L. Huggins, Eastman Kodak Co.; Prof. A. L. Patterson (chairman), Bryn Mawr College; Prof. L. Pauling, California Institute of Technology; Prof. F. Seitz, Carnegie Institute of Technology; Prof. A. N. Winchell, American Cyanamid Co.; and Dr. R. W. G. Wyckoff, National Institute of Health. The Committee will recommend to the National Research Council a permanent constitution for the American Section of the Union, and will also advise the Council with regard to any matters which are of general concern to crystallographers in the United States. The British National Committee for Crystallography was announced in *Nature* of March 13, p. 390.

Education in Industry and Commerce

THE Minister of Education has recently announced that Lieutenant-General Sir Ronald Weeks has accepted the chairmanship of the newly established National Advisory Council for Education in Industry and Commerce. The Council has been set up to consider the national aspects of the policies of the ten regional councils and academic boards which have been constituted to develop and co-ordinate schemes for higher technological education in their respective regions. Sir Ronald was deputy chief of the Imperial General Staff from 1942 until 1945 and is now deputy chairman of Vickers, Ltd., and chairman of the English Steel Corporation, Ltd.

Conference on the Education of the Young Worker

A CONFERENCE on "The Education of the Young Worker" will be held at Manchester College, Oxford, during July 12–17, under the auspices of the Oxford University Department of Education, whose director is Mr. M. L. Jacks. The Conference aims at bringing together representatives of all the voluntary and statutory organisations, of central and local government departments, and others concerned in the education, employment and welfare of young people between the ages of fifteen and twenty, who are no longer receiving full-time education. It is hoped to produce a statement of policy applicable to the needs of these young people, setting out as clearly as possible the goals to be achieved in further education, whether in county college, industry or during leisure time. Suggestions will be made for practicable methods by which these goals can be achieved through the right co-ordination and administration of all available resources to form an integrated service, and some form of agreement will also be sought on the recruitment and training of all personnel who will be responsible for these young people. Well-known people, especially experienced in some aspect of this work, have been invited to speak at the Conference. The Conference itself will be divided into eight Commissions, namely: (1) county colleges; (2) leisure-time activities; (3) education in and through the job; (4) education for and in the Services; (5) recruitment and training of personnel; (6) differentiation in provision between the sexes; (7) differentiation between town and country; (8) administration and co-ordination. Further information can be obtained from the Director, University Department of Education, 15 Norham Gardens, Oxford.

Feeding Times of British Birds

The Rev. John Lees has recently made observations into the winter feeding hours of robins, blackbirds and blue-tits (*British Birds*, **41**, No. 3; March 1948). These were made during the periods October 1945–March 1946 and October 1946–March 1947, and showed that there was a rough similarity between the feeding frequency of all three species. Each shows almost equal maxima in the forenoon and afternoon and a midday slackening of activity. Beyond this the differences are strongly marked. The robin has its maxima well separated, these being associated with the hours after sunrise and before sunset; the less active period over midday extends to about five hours. The blackbird has maxima close together, one and a half hours on each side of midday, the noon break being short and not pronounced. With the blue-tit the maxima are between those of the other two species and there is a well-defined break at midday.

British Bryological Society

The members of the British Bryological Society assembled at Buxton during March 30–April 6 for the annual general meeting and week of field excursions. In spite of somewhat varied weather conditions, the members, under the leadership of Messrs. R. H. Hall and F. A. Sowter, visited Kinder Scout, Lathkill Dale, Dovedale and Monks Dale, and a considerable amount of field-work was accomplished. Two visits were made to Kinder Scout; on the first occasion the party proceeded to the edge of Kinder plateau via Grinds Brook, and on the second visit the ascent was made by Ashop Clough. The results of the field-work will be published later in the *Transactions* of the Society. The annual general meeting was held on April 2, with the president, Mr. A. Thompson, in the chair; the secretary, Mr. E. C. Wallace, reported a considerable increase in the number of new members. Dr. W. Watson (Taunton) and Mr. W. R. Sherrin (South London Botanical Institute) were unanimously elected honorary members in recognition of their long and valuable services to bryology and bryologists.

Matter-Radiation Cycle

Referring to his communication entitled "The Matter-Radiation Cycle in the Cosmos (and the Second 'Law'): the Sun's Equilibrium" in *Nature* of December 27, 1947, p. 906, Mr. Alfred Lauck Parson writes: "The expression used for the temperature which could be reached by inter-stellar matter in imagined finite groups of nebulæ should have been

$$T_2 = T_1 \times \sqrt[4]{\frac{A_1(1-F)}{A_2\left\{F + \frac{1}{A_2}(1-F)\right\}}}$$

and not $T_2 = T_1 \times \sqrt[4]{(1-F)}$, T_1, T_2 being the temperatures of the stars and of the interstellar matter, A_1, A_2 their superficial areas, and F the fraction of radiation escaping at the assumed radius of the group. The change does not affect the general conclusion."

Colonial Service Appointments

The following appointments have been made in the Colonial Service: H. W. Hamlin, assistant conservator of forests, Tanganyika; H. S. H. Watson, assistant conservator of forests, Northern Rhodesia; J. R. Fletcher, inspector of mines, Malaya; A. J. MacNair, temporary agricultural (cocoa survey) officer, Gold Coast; J. Phipps, entomological biologist, Tanganyika; T. C. Stibbs, mining inspector, Lands and Mines Department, British Guiana; G. W. Lock (senior agricultural officer, Tanganyika), senior research officer, Tanganyika; A. E. S. McIntosh (senior agricultural officer, Federation of Malaya), deputy director of agriculture, Federation of Malaya; F. J. Pound (senior agricultural officer, Trinidad), deputy director of agriculture (crop husbandry), Trinidad; G. M. Roddan (deputy agricultural adviser, Colonial Office), deputy director of agriculture, Kenya; O. S. Swainson (senior agricultural officer, Zanzibar), director of agriculture, Zanzibar; S. G. Willimott (chemist, Department of Chemistry, Federation of Malaya and Singapore), chemist (soils), Federation of Malaya; H. A. Hay-Barclay (senior veterinary officer, Nigeria), regional assistant director of veterinary services, Nigeria; A. Fulton (senior veterinary officer, Gold Coast), director of veterinary services, Sierra Leone/Gambia; L. R. Hutson (chief veterinary officer, Leeward Islands), veterinary officer, Department of Science and Agriculture, Barbados; J. W. Macaulay (veterinary research officer, Northern Rhodesia), senior veterinary research officer, Northern Rhodesia; J. Morton (veterinary officer, Nigeria), regional assistant director of veterinary services, Nigeria; H. G. Stewart (veterinary officer, Uganda), senior veterinary officer, Uganda.

Announcements

Prof. Paul Fallot, professor of geology in the University of Nancy, has been elected a member of the Section of Mineralogy of the Paris Academy of Sciences, in succession to the late Léon Bertrand.

The Stephen Paget Memorial Lecture of the Research Defence Society will be delivered by Prof. P. A. Buxton on the occasion of the annual general meeting of the Society, to be held at the Royal Society of Tropical Medicine, London, on June 8. Prof. Buxton's address will be on "Tsetse Flies and the Development of Africa", and it will be illustrated by a film in colour.

John A. Harrison, assistant education officer of Surrey County Council, has been appointed director of the Educational Foundation for Visual Aids. Mr. Harrison has had considerable experience of the use of visual aids to education both in the Services and in civilian teaching. During 1931–45 he used visual aids almost continuously in all types of education in 1938, while holding a Carnegie research scholarship, he visited many American schools, givin particular attention to the use of visual aids.

An appointment is to be made shortly to th Dewar Research Fellowship, tenable in the Dav Faraday Research Laboratory of the Royal Institution. The Fellowship, which is of the value of £1,00 a year, is open to persons of either sex, and is for period of three years. The subject of research mus be related to the chemical or physical science Previous holders have been Prof. A. R. Ubbelohd of the Queen's University, Belfast, and Dr. Kathlee Lonsdale, of University College, London. Applications must be made by letter to the General Secretar Royal Institution, 21 Albemarle Street, London, W. before June 30.

Branched-Chain High Polymers

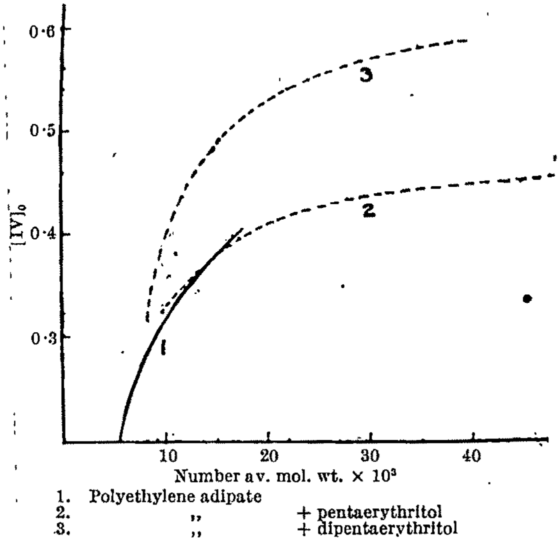
If two bifunctional molecules such as ethylene glycol and adipic acid are esterified in equal proportions, linear super-ester molecules are produced. In a similar way polyamides and polyurethanes may be produced, the chemistry of the process being such that only linear polymers are, in fact, formed. On the other hand, if one of the reactants contain three or more functional groups, for example, glycerol, then instead of linear molecules, branched molecules are first formed ; but these branched products soon join up into three-dimensional networks which are insoluble and, therefore, not suitable for detailed investigation. Between these two extremes there must inevitably be produced molecules containing branched chains which, if the chains are not indefinitely long, should be soluble. Owing to the rapidity with which the network stage is reached, it has not hitherto been possible to isolate and characterize branched-chain molecules possessing long branches. Yet it is of great interest to know something of the thermodynamic and hydrodynamic behaviour of solutions of such molecules. The only branched molecule of which the structure has been determined is amylopectin. Here, however, it is not possible to vary the length of the branches while keeping the number fixed. It is, moreover, just the kind of variation that must be produced if the necessary information about branched-chain molecules is to be obtained. The present communication describes the attempts that have been made to synthesize, characterize and measure the properties of branched-chain super-ester molecules.

The principle of the method involves the copolymerization of a small amount of polyfunctional compound such as pentaerythritol, dipentaerythritol, trimethylol propane, with ethylene glycol and adipic acid. The polyfunctional compound is added to a polyethylene adipate of a high degree of polymerization ; the polymer is then slightly depolymerized by heating at atmospheric pressure in nitrogen and then repolymerized, with the incorporation of the pentaerythritol, at 0·1 mm. of nitrogen. It proved possible to stop the reaction just short of the gel point, when polymers of a molecular weight much greater than that of the polyethylene adipate were obtained.

In order to characterize these polymers, it is necessary to measure the number average molecular weight by osmometry, and the number of chain ends or the number of points at which branching takes place. End-group determination proves to be most suitable. The method was tested with the parent polyethylene adipate, which was prepared by heating adipic acid with a threefold excess of glycol, no catalyst being present. The diglycol ester of adipic acid is first formed. This on further heating loses glycol, finally resulting in the formation of a super-ester with terminal hydroxyl groups.

A given weight of this ester was analysed for the total number of hydroxyl groups and the total number of molecules present measured by osmometry. It turned out there were on the average two hydroxyl groups per polymer molecule.

Using the same method with the supposedly branched polymers, it was found that those molecules containing pentaerythritol had four hydroxyl groups per molecule, and consequently must be cruciform in shape with the pentaerythritol nucleus at the centre. With dipentaerythritol, six hydroxyl groups per molecule are found, corresponding, therefore, to a molecule with six arms radiating from the dipentaerythritol nucleus as a star-shaped molecule. With trimethylol propane, $C_2H_5C(CH_2OH)_3$, the molecules contain six hydroxyl groups, implying, therefore, the incorporation of two trimethylol propane units before gelling sets in. Thus the structure of this polymer will be double *Y*-shaped, the two branches which it contains originating from two different points instead of the same point as with the pentaerythritol polymers. By varying the proportion of the polyfunctional alcohol, it is possible to prepare a series of molecules of the above-mentioned structures of different molecular weights from 10,000 up to about 50,000. This fact proves conclusively that these molecules contain long branches, because by this technique it is difficult to prepare linear super-esters with molecular weights exceeding 10,000.



The intrinsic viscosity of solutions in chloroform are plotted as a function of molecular weight in the accompanying graph. With the linear molecules (curve 1) the intrinsic viscosity $[\eta]$ is not linearly proportional to molecular weight ; the exponent in the equation $[\eta] = K(MW)^a$ is 0·9. With the branched-chain polymers, the intrinsic viscosity increases rapidly at first but tends to a maximum, the maxima being different for curves 2 and 3. The fact that the value of $[\eta]$ tends to become independent of molecular weight is in agreement with the Einstein theory of the viscosity of colloidal solutions, if it is assumed that the molecules are tending to a spherical shape in solution. The maximum value of the intrinsic viscosity of 0·6 is, however, much smaller than the Einstein value of 2·5. It will be observed that the linear polyethylene adipate and the cruciform adipate have similar intrinsic viscosities in the range 10,000–20,000 in molecular weight. Thus it would not be possible by measurements of intrinsic viscosity and number average molecular weight above to discriminate between molecules of such different structure. In fact, one general conclusion from these experiments is that branching in a high-polymer molecule is unlikely to be easily detected even though an authentic linear polymer of the same number average molecular weight were available for comparison. In a similar way, the variation of viscosity with concentration of the branched-chain molecules as compared with linear molecules is in qualitative agreement with the theories already put forward, but the results are not nearly so clear cut as the theories would predict.

Catalytic Poisons and Magnetic Susceptibility

THE alkyl sulphides are powerful catalytic poisons for palladium, and the nature of the adsorption link is therefore of great interest. On chemical grounds, Maxted[1] has suggested a co-ordinate link from the sulphur atom to the metal. Here we record some preliminary measurements on the change in magnetic susceptibility of palladium due to adsorption of dimethyl sulphide. We conclude that electrons from the sulphur atom enter the *d* band of the metal (in an analogous way to the electrons from *dissolved* hydrogen atoms[2]).

A finely divided sample of palladium powder (prepared by reduction of palladium chloride in glycerine by hydrogen gas at 150° C.) was evacuated in an ampoule at 150° C., sealed off, and its susceptibility measured by the Sucksmith method[3]. The ampoule was then reattached to the vacuum apparatus and the palladium saturated with dimethyl sulphide gas at 20° C. The amount adsorbed was measured, the ampoule resealed and measured in the magnetic balance.

Column 2 of the accompanying table shows the change in susceptibility of the palladium powder expressed as a percentage change on the original value χ. Column 3 gives the percentage change in χ due to the effect of adsorption on the palladium alone; that is, it is the value in column 2 *minus* the calculated diamagnetic susceptibility of the adsorbed dimethyl sulphide.

$\frac{100\ a^*}{b}$	$100\frac{\Delta\chi}{\chi}$	$100\left(\frac{\Delta\chi}{\chi}\right)_{\text{Pd}}$	$100\left(\frac{\Delta\chi}{\chi}\right)_{\text{calc.}}$
27	10·1	8·0	13·5
23	7·9	6·0	11·5

* *a* moles dimethyl sulphide adsorbed on *b* gm. atoms palladium powder.

The effect of the dimethyl sulphide is outside the experimental error of 2 per cent on χ, and is of the right order to be expected if one electron from the dimethyl sulphide enters the *d*-band of the metal. Since dimethyl sulphide is an easily condensable gas, the adsorption will correspond to *at least* two monolayers; that is, a van der Waals layer on top of a chemisorbed layer. Only the chemisorbed layer will affect the susceptibility, and this will contain *up to* half the adsorbed quantity in column 1. At this stage we can do no more than assume that a chemisorbed molecule transfers an electron to a vacant surface *d* orbital, and thus the susceptibility of the surface palladium atoms is reduced to zero (there is 0·55 mole in the *d*-band per palladium atom[2]). This would then yield the calculated decrease in susceptibility shown in the last column.

It is not worth discussing the discrepancy between observed and calculated figures until experiments with clean surfaces have been made. The main point of contrast is that if the electrons entered the *s*-band of the metal, the susceptibility change would have been immeasurably small.

It is hoped to develop this experiment along more quantitative lines, since it offers an approach to an important aspect of adsorbed layers. These preliminary measurements were made in the Physics Department of the University of Bristol, and we are grateful to Drs. H. Heitler and L. C. Jackson for their help and advice.

Synthetic Pentapeptides Related to Gramicidin-*S*

THE polypeptide nature of several antibiotics is of considerable interest. As recent work in this field overlaps to some extent with our own, we wish to give a preliminary account of our studies on synthetic peptides related to gramicidin-*S*.

Synge[1] extended the limited data published by Russian workers[2–4], and suggested that gramicidin-*S* was the hydrochloride of a basic peptide with a stoichiometric minimum unit containing equimolecular proportions of the five amino-acids, *L*-ornithine, *L*-proline, *L*-valine, *L*-leucine and the unnatural *D*-phenylalanine. Each stoichiometric unit contained one free amino group but no free carboxyl groups. The free amino group was later identified[5] as the δ-amino group of ornithine, and gramicidin-*S* was formulated as a cyclic peptide of five amino-acids linked through their α-amino and carboxyl groups. Degradative studies involving the technique of partition chromatography furnished strong evidence for the structure [α-(valyl-ornithyl-leucyl-phenylalanyl-prolyl-)]$_n$ [6]. On the basis of the physical information so far available, gramicidin-*S* is best formulated as a cyclopentapeptide, or as a cyclodecapeptide where the above unit occurs twice in a closed peptide chain.

In the hope that some light might be thrown on the origin of the striking antibiotic action of this peptide, we decided to carry out parallel syntheses so as to obtain two pentapeptides with phenylalanine present in both its optically active forms. Numerous alternative routes to such a pentapeptide might be envisaged. After several different combinations had been tried, it was decided that for ease of handling, which was a dominant consideration, synthesis of a tripeptide from leucine, phenylalanine and proline, and the coupling of this tripeptide with a dipeptide from valine and ornithine, would have a reasonable chance of success. For all syntheses carbobenzoxy derivatives were employed according to Bergmann's general procedure, and coupling was effected in each case through the acid azide.

Cbzo-L-phenylalanine hydrazide was converted to the azide, coupled with *L*-proline ethyl ester, and the carbobenzoxy group removed by catalytic reduction. The dipeptide ester with *Cbzo-L*-leucine azide gave *Cbzo-L*-leucyl-*L*-phenylalanyl-*L*-proline ethyl ester. The acylated tripeptide ester could not be crystallized, but analysed satisfactorily (found: C, 67·2; H, 7·3; N, 8·18; theory: C, 67·1; H, 7·3; N, 7·84 per cent). It was used for coupling with the appropriate dipeptide without further purification.

For the synthesis of the isomeric tripeptide a modified procedure was used which gave crystalline intermediates. *Cbzo-L*-leucine azide coupled with *D*-phenylalanine methyl ester to give *Cbzo-L*-leucyl-*D*-phenylalanine methyl ester, m.p. 110°. The hydrazide (m.p. 170°) from this ester gave an azide which was condensed with *L*-proline methyl ester; the resulting acyltripeptide ester was purified as the hydrochloride after removal of the carbobenzoxy group. The tripeptide methyl ester hydrochloride $[\alpha]_D^{20} = -38{\cdot}9°$ [anhydrous methanol, $C = 2{\cdot}0$] melted at 240°.

The two optically isomeric tripeptide hydrochlorides were tested *in vitro* against *Staphylococcus aureus*, *Streptococcus hæmolyticus* and *Escherichia coli*. Both peptides inhibited growth at a concentration of 1–2 mgm./ml., but were inactive at lower concentrations.

For preliminary experiments on open-chain pentapeptides we used the readily obtainable *DL*-ornithine rather than the rarer *L*-ornithine, as we did not consider that use of an optical mixture of *L*-valyl-*L*-ornithine and *L*-valyl-*D*-ornithine would affect the validity of our conclusions. *Cbzo-L*-valyl-δ-*Cbzo-DL*-ornithine methyl ester, was prepared by the azide method and crystallized readily, m.p. 150°. This was converted through the hydrazide to the azide, and coupled with both the tripeptide esters already described. Both the dicarbobenzoxypentapeptide esters were difficult to handle; they set to stiff gels when attempts were made at recrystallization. After repeated precipitation of one gel, a product, m.p. 128–132°, was obtained which analysed satisfactorily for *Cbzo-L*-valyl-δ-*Cbzo-DL*-ornithyl-*L*-leucyl-*L*-phenylalanyl-*L* proline ethyl ester (found: C, 65·0; H, 7·4; N, 9·85; theory: C, 65·2; H, 7·2; N, 9·5 per cent). After five further 'crystallizations' from aqueous methanol, the small quantity of material remaining melted at 164° and again analysed satisfactorily.

The second, isomeric acylated pentapeptide ester melted at 198–200°, after purification by the same means, and analyses were satisfactory for *Cbzo-L*-valyl-δ-*Cbzo-DL*-ornithyl-*L*-leucyl-*D*-phenylalanyl-*L*-proline methyl ester (found: C, 64·5; H, 7·1; N, 10·0; theory: C, 64·8; H, 7·1; N, 9·7 per cent). As a final check on the identity of the two peptides, these were hydrolysed and the hydrolysates subjected to chromatographic analysis on paper by the usual technique[7]. The presence of the required five amino-acids was demonstrated by comparison with an artificial mixture.

The above work was essentially of an exploratory nature and was carried out on the smallest scale consistent with the requirements of the biological tests. We are now repeating the synthesis of the *LLLDL*-pentapeptide on a larger scale using *L*-ornithine so as to eliminate any doubts about the optical purity of the final product.

No significant difference in antibacterial action was apparent between 'natural' and 'unnatural' isomers at either the tripeptide or the pentapeptide stage. These results support the view already expressed[8] that antibiotics containing *D*-amino-acids are active, not because they have this character in common, but rather in virtue of their specific structures, of which the *D*-amino-acids must be regarded as an integral part.

Crowfoot (private communication) has expressed the opinion from a study of models that *D*-configuration of some of the constituent amino-acids in a peptide such as gramicidin-*S* would facilitate cyclization. It is thus reasonable to postulate that the activity of this peptide is a function of its cyclic nature. When larger supplies of open-chain pentapeptide become available, we hope to study the effect of polymerization and, if possible, of cyclization, on antibacterial action. A full account of this work will be published elsewhere.

We are indebted to Dr. A. T. Fuller for carrying out the biological tests.

Reversion: a New Procedure in Absorptiometry

MANY metals form coloured complexes with dithizone, and the successful use of this reagent for estimating one of them in a mixture demands a careful selection of organic solvent, a rigorous control of *p*H and other variables such as duration of shaking, nature and amount of neutral salts present, the concentration of excess dithizone, and the concentration of 'masking' reagents capable of competitive complex formation with interfering metals[1]. The coloured metal complexes (yellow, red, violet, etc.) modify the colour of the green solution containing excess dithizone giving a 'mixed-colour' extract, and by absorptiometric measurements the proportion of metal complex can be estimated with reference to calibration curves obtained by treating known amounts of metal by the standardized procedure. Such curves are commonly valid only for one initial concentration of dithizone, and error may be introduced in view of the well-known impermanence of this reagent. The theoretically obvious solution for such systems with two coloured components is to measure the transmittency at two appropriate wave-lengths; but this involves a burdensome amount of preliminary work for, in effect, a family of calibration curves must be constructed to cover all possible variations in reagent concentration and in the amount of metal taken for analysis[2].

In a systematic study of the estimation with dithizone of traces of mercury in biological materials[3], we have shown that in the absence of suitable masking reagents mercury cannot be extracted quantitatively, even under optimum conditions, without co-extraction of more or less copper. Both theoretically and practically it is to be anticipated that this interference by copper (which is returned as mercury) will increase as the concentration ratio copper/mercury in the analysis sample increases. A similar situation will be encountered in other metal dithizone systems should the prescribed conditions of extraction be inadvertently departed from or the masking agent prove inadequate to the demands made upon it. In these circumstances the 'mixed-colour' extract will contain, besides excess dithizone and the metal complex being estimated, varying amounts of one or more unwanted metal complexes. No provision has been made for this contingency in any of the procedures described hitherto, and we have therefore developed a new approach.

If E_m is the optical density of a mixed-colour extract measured in a cell of length l, containing concentrations C_c of metal-dithizonate of formula MDz_n, C_d of excess dithizone, and C_i of other coloured impurities (foreign metals co-extracted as dithizonates, coloured impurities from the decomposition of reagent or from biological digests, etc.) of extinction coefficients ε_c, ε_d and ε_i respectively, then

$$E_m = l\,(C_c\varepsilon_c + C_d\varepsilon_d + \Sigma C_i\varepsilon_i).$$

If now the organic extract is shaken with an aqueous solution of some *specific* reagent which will decompose only the desired metal complex, returning the ions M^{n+} to the aqueous phase and liberating nC_c equivalents of dithizone in the organic layer, the optical density (at the same wave-length) will change to a value given by

$$E_r = l\,(nC_c\varepsilon_d + C_d\varepsilon_d + \Sigma C_i\varepsilon_i).$$

This process we term 'reversion'. The change in optical density, the reversion value, given by

$$R = E_r - E_m = l\,(n\varepsilon_d - \varepsilon_c)\,C_c,$$

is seen to be a linear function of the concentration of metal being estimated, and is independent of the concentration of dithizone taken.

Using a Hilger 'Spekker' absorptiometer with an Ilford Orange Filter No. 607, our reversion curve for mercury is linear over the range 0–2·4 p.p.m. A change in optical density of 0·1 corresponds to 0·33 p.p.m. of mercury, a sensitivity materially greater than that of the best contemporary methods[4]. Since $\varepsilon_d \gg \varepsilon_c$ at the wave-length chosen, all measurements involve essentially estimates of the same species (dithizone), and the same lamp-filter combination is used when determining both E_m and E_r. Indeed, if the concentration axis is graduated in units of gram-equivalents, a single calibration curve can be used, with no serious loss of accuracy, for the estimation of such varied metals as silver, lead, mercury and bismuth[5].

The major advantages of reversion procedure are: (1) standard solutions of dithizone are not required and changes in strength on keeping are unimportant; (ii) errors due to metals or other coloured materials co-extracted (term $\Sigma C_i\varepsilon_i$ above) are eliminated; and (iii) when estimating metals such as lead and cadmium where excess dithizone passes into the aqueous layer to an extent dependent upon the alkalinity of this medium, slight variations in the pH of extraction can introduce no error. The general principle of reversion is equally applicable to other suitable systems; for example, metals and oxine, or *o*-nitrosophenol, etc., or to measurements on mixtures absorbing in the ultra-violet or infra-red.

Gases Liberated from Explosions Initiated by Impact

TRUE detonation in high explosives normally gives as the major products gases such as carbon dioxide and monoxide, water, nitrogen and hydrogen[1,2], the relative quantities obtained being in general accordance with calculations based on equilibrium considerations. The thermal decomposition of explosives, on the other hand, gives more complicated products such as nitrogen oxides, aldehydes and complex condensation products, which may undergo further secondary reactions[3,4]. It was of interest to see whether the products from impact-initiated explosions would approximate more closely to those of detonation or thermal decomposition. Results with the two nitric esters, nitroglycerin and pentaerythritol tetranitrate, and the nitroamine, *cyclo*-trimethylenetrinitramine, reveal an intermediate behaviour. The figures are given in the accompanying table. The impacts were carried out in a vacuum apparatus[5]. For comparison, some figures for the explosive decomposition of nitroglycerin and pentaerythritol tetranitrate are quoted.

COMPOSITION OF GASES (PER CENT)*

	NO_2	NO	N_2O	N_2	CO_2	CO	H_2	O_2
Nitroglycerin								
Detonation[6]	—	—	—	32·0	63·1	—	—	4·9
Impact	—	29·7	2·3	11·7	28·8	22·5	5·0	—
Decomposition (180° C.)	—	50·3	1·0	2·1	17·2	28·9	0·5	—
Pentaerythritol tetranitrate								
Detonation[2]	—	5·3	—	22·8	37·0	26·7	6·8	1·4
Impact	—	24·3	5·3	9·4	19·1	35·4	6·5	—
Decomposition (210° C.)	12·0	47·6	9·5	1·6	6·3	21·0	2·0	—
cyclo-Trimethylene-trinitramine								
Impact	—	—†	11·3	43·3	18·8	21·3	5·3	—
Decomposition (267° C.)	—	22·5	22·8	31·0	13·2	8·7	1·8	—

* The water content was not determined. Considerable quantities of formaldehyde were noted in impact and decomposition experiments with *cyclo*-trimethylenetrinitramine and pentaerythritol tetranitrate.

† On some occasions a little nitric oxide was formed.

The results are consistent with the view that the decomposition under impact conditions occurs by a very similar mechanism to that operative in thermal decomposition, the secondary reactions of aldehyde oxidation proceeding to a further extent probably on account of the higher temperatures. The results are in harmony with the hypothesis of a thermal origin of impact-initiated explosions and with the slow initial burning velocities observed with the rotating-drum camera[7].

Our thanks are due to Mr. L. Phillips for analysing the gases from the thermal decomposition of nitroglycerin. This communication is published by permission of the Chief Scientist, Ministry of Supply.

'Semaphore' Numerals

ENOUGH is now known, as the Royal Society discussion on the subject on March 4 made clear [see *Nature*, May 8, p. 712], about the logical, physical and mechanical principles, and of the engineering, to make the existence of a number of high-speed digital computing machines a matter of time, and of comparatively short time, only. We can, in fact, do arithmetic at very high speed.

But the speed of any composite process is governed mainly by the speed of its *slowest* component. At present, 'input' and 'output' cannot take place at speeds in any way comparable with the attainable speed of computation. The machine should be able to do *all three* of the 'three R's' at comparable speeds—it must learn to Read and to wRite, and to do these quickly, as well as to do aRithmetic! Reading is the most important, for it should occur at a rate per digit comparable with an 'addition time'; but 'output' will not slow down the process if recording a result takes no longer than the chain of arithmetical operations which produces it.

Towards the end of the recent discussion, Mr. Wilkinson remarked that he had given some thought to the processes by which the human eye recognizes the numerals as printed or written, and seemed to imply that present forms would prove difficult for the low-grade intelligence of the robot to recognize. The alternative is, presumably, to introduce a new, simple and systematic set of numerals, simple enough for the robot but usable also by the human, so that mathematical tables might be printed in a form universally available, needing *no further coding* for the robot. We present here a possibility in this direction. While it would be unwarrantable optimism to presume that it is the last word, it is upon some such lines that progress depends, and a concrete suggestion may stimulate thought and discussion which vague generalities would not.

Working in the binary scale would be too cumbersome; working in some power of 2, say, 8 or 16, would not be too remote from the decimal scale—but it would entail the re-learning of arithmetic, 'multiplication tables and all that'. Indeed, a proposal to abandon the decimal system would be too revolutionary to stand any chance of general acceptance. But, fortunately, $10 - 1 = 3^2$, so that a dual use of a trinity of symbols will suffice. Such a possibility is presented by the three positions of a semaphore, upright, or inclined to left or right. The combination of upward-pointing and downward-pointing triads gives us the nine digits. A scheme, easy to write, easy to read—and *very* easy to remember—is presented in Fig. 1.

Fig. 1

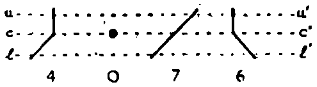

Fig. 2

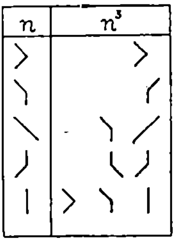

Fig. 3

The provision of a zero can be met by a central dot (a mere blank is not satisfactory). In writing, the comma can (as it now does in many countries) serve as a decimal point, and a lower point could—if desired—be used to indicate multiplication, but these would not be relevant to 'reading' by the robot.

The machine 'scanning' of the new numerals could be horizontally, for serial operation. Two 'eyes' are essential, but a third central one is desirable, to provide a time-scale and to sense the zeros.

The method is indicated by the dotted lines in Fig. 2. The three eyes will scan the lines uu', cc', and ll', and the impulses due to crossing the lines or the dot will be interpreted by circuits in the machine, so that the number read is fed into the appropriate register.

If this, or some similar, suggestion is accepted, it remains to fix an agreed standard size and spacing, and to use these numerals in printing all new mathematical tables. Re-coding of existing tables could also be undertaken. Some idea of appearance is given in Fig. 3, representing the beginning of a table of cubes.

Visual users of mathematical tables could rapidly master (and indeed use) the new code, and the problem of making robots wRite would be in no way more difficult.

Angular Distribution of Radioactive Disintegration Products

THE thermodynamics of the orientation of nuclei by strong magnetic fields at very low temperatures was worked out by Simon[1] in 1939. He found that with fields of 100,000 gauss and temperatures of 0·01° K., that is, under conditions which can be realized experimentally, the entropy of nuclear spin systems should be decreased by about 20–30 per cent, and would remain, of course, at this reduced value after adiabatic demagnetization. This would be sufficient to influence properties which depend on nuclear orientation, and the first experiments he contemplated were on the angular distribution of radioactive disintegration products originating from a partially oriented nuclear spin system. Preparations for these experiments, which were interrupted by the War, are now going ahead at the Clarendon Laboratory. It should be added that in the meantime experiments on nuclear induction have shown that the 'reaction velocity'—at least in some nuclear spin systems—is still very high even at temperatures as low as 1° K. [2].

In the present note, theoretical calculations have been made of the nature and magnitude of the effects to be expected. These are based on the state of the oriented system before the adiabatic demagnetization, as this is easier to realize in experiment. In making these calculations, the use of any particular 'models' of the process of disintegration has been avoided so far as possible, since it is possible to go a long way by applying some of the more elementary results of the theory of representations of the group of rotations to eigenstates of angular momentum.

The results so far obtained are as follows. Let $F(\theta)$ denote the angular distribution of the emitted particles (intensity in direction of emission θ, θ being the angle between the direction of emission and the direction of the orienting magnetic field). Then for a nucleus of initial spin J,

$$F_J(\theta) = \sum_M c_0{}^M \cosh M\beta + \sum_p \{\sum_M c_p{}^M \cosh M\beta\}.\cos^{2p}\theta, \qquad (1)$$

where p is a positive integer $\leqslant J$; M is $-J, -J+1, \ldots, +J$; β is $\mu H/kTJ$; μ is magnetic moment of initial nucleus; H is magnetic field; T is absolute temperature; k is Boltzmann's constant; $c_0{}^M$, $c_p{}^M$ are constants independent of H, T, θ, but otherwise dependent on the particular transition considered;

$$\sum_M c_p{}^M = 0, \text{ for all values of } p > 0.$$

This form of the function $F(\theta)$ holds irrespective of the nature and angular momenta of the particles emitted, and of whether they are emitted singly or together with other particles (as, for example, in beta emission). The term particle here includes photons. The constants $c_0{}^M$, $c_p{}^M$ are undetermined by the general method used in establishing this formula.

A particular result is that for $J = 1/2$ there can be no directional effects.

If $\mu H/kT \leqslant 1$, a sufficiently accurate form of expression (1) is

$$F_J(\theta) \propto 1 + (\mu H/kT)^2 (k_1 \cos^2\theta + k_2 \cos^4\theta + \ldots + k_p \cos^{2p}\theta).$$

Here $p \leqslant J$; the constants $k_1, \ldots k_p$ are, of course, also undetermined.

These formulæ do not include the deflecting effect after emission of the magnetic field on the emitted particle (if charged), as this effect depends on the experimental arrangement, and can be calculated classically since the de Broglie wave-length of the particles will be small compared with the dimensions of the apparatus.

A more detailed method has also been used to calculate the angular distribution of γ-rays emitted from oriented nuclei in a 2^l-pole transition; this method is also being applied to alpha and beta emission.

Let $F_{JJ'}(\theta)$ denote the angular distribution resulting when a nucleus of initial spin J emits a 2^l-pole γ-ray and the final nucleus has spin J'. Then

$$F_{JJ'}(\theta) = \sum_{M=-J}^{+J} e^{M\beta} \sum_{M=-l}^{+l} \left(c_{M-m,m}^{\;JJ'l}\right)^2 . T_{lm}(\theta),$$

where

$$T_{lm}(\theta) = \tfrac{1}{2}(l-m+1)(l+m)(P_l{}^{m-1})^2 + m^2 (P_l{}^m)^2 + \tfrac{1}{2}(l+m+1)(l-m)(P_l{}^{m+1})^2.$$

Here M is z minus component of total angular momentum J of initial nucleus; m is z minus component of total angular momentum l of emitted photon (that is, $m = -l, -l+1, \ldots, +l$); $P_l{}^m$ is a normalized associated Legendre function of order l; β has the same meaning as above.

The coefficients $c_{M-m,m}^{\;JJ'l}$ are those which occur in the group theoretical derivation of the formulæ for the 'vector addition' of quantized angular momenta. They may be calculated from the formula,

$$c_{m_1 m_2}^{Jj_1j_2} = \sum_{\nu=0}^{\lambda} (-1)\, \frac{\nu\sqrt{\{(j_1+m_1)!\,(j_1-m_1)!\,(j_2+m_2)!\,(j_2-m_2)!\,(J+M)!\,(J-M)!\}}}{(j_1-m_1-\nu)!\,(j_1+m_1-\lambda+\nu)!\,(j_2+m_2-\nu)!\,(j_2-m_2-\lambda+\nu)!\,\nu!\,(\lambda-\nu)!}$$

where $\lambda = j_1 + j_2 - J$ and $M = m_1 + m_2$ (see Van der Waerden[3]).

The expression for angular distribution has been evaluated in the case of dipole transitions ($l = 1$). In this case we can have $J' = J+1, J, J-1$, and then, provided $J \geqslant 1$ (there are no effects for $J = 0$ or $\tfrac{1}{2}$),

$$F_{J,J+1}(\theta) \doteq 1 + \left(\frac{H\mu}{kT}\right)^2 . \frac{1}{40} . \frac{2J-1}{J}. \cos^2\theta,$$

$$F_{J,J-1}(\theta) = 1 + \left(\frac{H\mu}{kT}\right)^2 . \frac{1}{40} . \frac{(J+1)(2J+3)}{J^2} \cos^2\theta,$$

$$F_{J,J}(\theta) = 1 - \left(\frac{H\mu}{kT}\right)^2 . \frac{1}{40} . \frac{(2J-1)(2J+3)}{J^2} \cos^2\theta,$$

provided in each case $H\mu/kT \leqslant 1$.

Inserting numerical values, we may write

$$F_{JJ'}(\theta) = 1 + 3{\cdot}34 \times 10^{-11} \left(\frac{H(\text{kilogauss}) \times \mu(\text{nuclear magnetons})}{T\,(°\text{ K.})}\right)^2 f(J, \delta J). \cos^2\theta.$$

Some values of $f(J, \delta J)$ are given in the table below:

δJ	$f(J, \delta J)$	Values of $f(J, \delta J)$ $J = 1$	$3/2$	$9/2$	$11/2$
$+1$	$(2J-1)/J$	1	1·3	1·8	1·8
-1	$(J+1)(2J+3)/J^2$	10	6·6	3·3	3·0
0	$-(2J-1)(2J+3)/J^2$	-5	$-5{\cdot}3$	$-4{\cdot}7$	$-4{\cdot}6$

If we take, say,

$T\,(°\text{ K.}) = 0{\cdot}01$;
$\mu(\text{nuclear magnetons}) = 3$;
H/K gauss $= 100$;

the resulting departure from spherical symmetry is of the order of $0{\cdot}03\,f$, that is, it lies between 3 and 30 per cent.

No definite conclusions can, of course, be drawn from this last calculation as to the magnitude of the effect in the case of higher multipole emission, though it seems possible that this will be of the same order as in the dipole case.

I would like to express my thanks to Prof. M. H. L. Pryce for the interest he has taken in these calculations.

Capture of Negative Mesons by Nuclei

Several writers[1] have commented on the unexpectedly long period which has been found for the nuclear capture of negative mesons from cosmic radiation at low altitudes (about 10^{-6} sec. in aluminium[2]). It has been estimated[3] that if this radiation fell on matter, the mesons would take about 10^{-12} sec. to be slowed down by Coulomb interactions and to fall into 'K-orbits' around the nuclei. Consequently, the experimental value of 10^{-6} sec. is the period for nuclear capture of a meson from the K-orbit[4], in marked contrast to the value of 10^{-16} sec. or less which has been predicted[3] on the assumption that nuclear particles interact with each other through this meson field alone (apart from Coulomb interaction). The estimate of 10^{-12} sec. for the slowing-down time has been questioned by Fröhlich[5], but it seems to be generally believed that the time taken is much less than 10^{-6} sec. and that there is, in fact, a big discrepancy between the experimental and theoretical values for the nuclear capture period.

It has been suggested[6,7] that the observations can be explained on the hypothesis that there are two kinds of meson: a heavy meson which interacts strongly with nuclear particles and which does not penetrate appreciably to sea-level, and a light meson which interacts only weakly with nuclear particles and which is found at low altitudes. The observations of Powell and co-workers[7] suggest that the heavy meson is capable of disintegrating spontaneously into a light meson and a neutral particle of comparable mass; other experimental evidence indicates that the light meson is also unstable, decaying spontaneously with a half-life of about 2×10^{-6} sec.[8] into an electron and, presumably, a neutral particle. (Recent experiments by Hincks and Pontecorvo[9] indicate that this neutral particle, if it exists, ionizes less strongly than a gamma-ray.)

It is tempting to suppose that the interaction of the heavy mesons with nuclear particles is connected with the nuclear forces and that there is no *direct* coupling between the light mesons and nucleons. There is, however, an indirect interaction between light mesons and nucleons by virtue of the coupling implied in the disintegration of heavy mesons into light mesons. According to the hypothesis which we wish to discuss, positively and negatively charged heavy mesons exist, which differ only in their electric charge and which are to be identified with Powell's π- and σ-mesons respectively. For the present discussion, we shall use the single symbol π to represent them. We use the symbol μ to denote a light meson of either charge, and ρ the neutral meson associated with the disintegration of π-mesons.

The μ-decay of the π-meson can be written in symbolic form

$$\pi\text{-meson} \rightarrow \mu\text{-meson} + \rho\text{-meson}. \qquad (A)$$

Most theories of neutral particles lead to the conclusion that, if such a reaction is possible, then so is the reaction:

$$\mu\text{-meson} \rightarrow \pi\text{-meson} + \rho\text{-meson}. \qquad (A')$$

The forces between nuclear particles are due to reactions of the type

$$\text{neutron} \rightarrow \text{proton} + \pi^{-}\text{-meson}. \qquad (B)$$

We can now assume that the reactions

$$\begin{tikzcd}
 & \begin{array}{c}\text{Proton} + \\ \pi^{-}\text{-meson} + \\ \rho\text{-meson}\end{array} \arrow[dr] & \\
\text{Proton} + \mu^{-}\text{-meson} \arrow[ur] \arrow[dr] & & \text{Neutron} + \rho\text{-meson} \quad (C) \\
 & \begin{array}{c}\text{Neutron} + \\ \pi^{+}\text{-meson} + \\ \mu^{-}\text{-meson}\end{array} \arrow[ur] &
\end{tikzcd}$$

account for the nuclear capture of μ^{-}-mesons, in contrast to the reaction

$$\text{proton} + \mu^{-}\text{-meson} \rightarrow \text{neutron}$$

on which the estimate of 10^{-16} sec. mentioned above was based. In consequence of our assumption of zero direct coupling between nucleons and μ-mesons, we would have zero probability for such a one-stage reaction; we must have recourse to a second-order perturbation calculation with intermediate states as shown in (C).

For the sake of obtaining orders of magnitude for the half-lives of reactions A and C, we consider the case in which the meson wave-functions are scalar and the interaction terms involve no derivatives. We then find that the half-life τ for spontaneous disintegration of a π-meson (of either charge) at rest (A) is given by

$$\frac{1}{\tau} = \frac{1}{8\pi} \frac{f^2\hbar^3}{m_\pi^2 c} \frac{m_\mu c^2}{\hbar} \frac{v_\mu}{c}, \qquad (1)$$

where f is the coupling constant for the reaction (A), m_μ, m_π are respectively the masses of the μ- and π-mesons and v_μ is the velocity with which the μ-meson is emitted. We estimate that the half-life τ_c for nuclear capture of a μ-meson from the 'K-orbit' through the mechanism (C) is given by

$$\frac{1}{\tau_c} \sim \frac{1}{4\pi^2} \frac{f^2\hbar^3}{m_\pi^2 c} \frac{g^2}{\hbar c} \left(\frac{e^2}{\hbar c}\right)^3 Z^4 \left(\frac{m_\mu}{m_\pi}\right)^2 \frac{m_\rho c^2}{\hbar} \frac{p_\rho}{m_\rho c}, \qquad (2)$$

where g is the coupling constant for reaction B, Z is the atomic number and m_ρ, p_ρ are respectively the rest mass and momentum of the emitted ρ-meson. In obtaining this estimate, we performed the calculations for the case of a free μ-meson; we then assumed that the probability per second for capture from the K-orbit was proportional to the probability density near the nucleus, given by the ordinary wave mechanics of a Coulomb centre of attraction. The result then also depends on the square magnitude of a nuclear matrix element, similar to those occurring in the theory of nuclear β-decay; the value of this matrix element will depend on the initial and final nuclear states and may accordingly be difficult to compute very accurately. It seems plausible to us to assume the value Z for the square magnitude of this matrix element, averaged over the initial nuclear states and summed over the final ones.

Substituting the following numerical values in (1) and (2): $Z = 13$, $\tau_c = 10^{-6}$ sec.[2], $e^2/\hbar c = 1/137$, $g^2/\hbar c = 0{\cdot}1$ (from the strength of nuclear forces), $m_\pi/m_\mu = 1{\cdot}6$ (Powell's latest results are $m_\pi/m_\mu = 1{\cdot}64 \pm 0{\cdot}11$, $m_\mu/m_e = 205 \pm 20$ [10]), $p_\rho/m_\rho c = 1$, m_ρ/m_μ

$= \frac{1}{2}$ (our estimates based on Powell's results for m_π/m_μ), and $v_\mu/c = \frac{1}{3}$ (from Powell's results[7]); we obtain the value 10^{-14} for $f^2\hbar^3/m_\pi^2c$, the dimensionless constant for the strength of the π-meson interaction with the μ- and ρ-meson fields.

This gives 4×10^{-8} sec. for τ, the half-life for spontaneous μ-decay of the π-meson.

Marshak and Bethe[6] have estimated that the available experimental data impose upper and lower limits of 3×10^{-7} sec. and 4×10^{-11} sec. respectively on the value of τ; the upper limit may with less certainty be reduced to 2×10^{-8} sec. Our estimate for τ agrees with these figures, showing that the theory discussed above is consistent with the value of 10^{-6} sec. for τ_c.*

Other similar theories can be formulated; indeed, if one assumes (as we did above) that the π-mesons alone have direct coupling with nucleons, then the data on nuclear forces can probably best be explained by taking a pseudoscalar wave function to describe the π-meson field. Any variations of this type would probably not alter the above estimates for τ by more than a factor of ten, and consequently such theories would probably also be consistent with the above-mentioned data. Marshak and Bethe[6] have shown that the above data can be accounted for on a similar theory; on their theory a π-meson decays into a μ-meson and a neutrino, and nuclear particles have a direct coupling to both π-meson and neutrino fields.

Another consequence of the above theory may be noted. The experimental evidence indicates that the scattering of negative μ-mesons by nuclei is effectively due to the Coulomb forces alone. The very small value for the interaction constant $f^2\hbar^3/m_\pi^2c$ which we obtained above shows that on this theory the effects of 'π-meson forces' on the nuclear scattering of μ-mesons are indeed negligible compared with the effects of Coulomb forces.

I wish to thank Prof. Pryce for suggesting these calculations and for helpful discussions.

* *Note added in proof.* Our estimate agrees with the value $\tau = 6 \times 10^{-8}$ sec. suggested recently (Greisen, K. I., *Phys. Rev.*, **73**, 521; 1948) to explain the experimental data on the energy spectrum of heavy mesons far underground.

Cloud Chamber Investigation of Straggling of Short-Range Particles Produced by Slow Neutron Reactions

A STUDY of the range distribution of particles produced by slow neutron disintegrations of gas nuclei in a cloud chamber offers especially favourable conditions for determining the straggling coefficient since, in such circumstances, the difficulty of producing a source of homogeneous particles is avoided.

In previous investigations of the reaction energy in slow neutron processes[1], a cloud chamber was used which was filled with air at low pressure or with a gas mixture containing the vapour of boric acid ester; the following reactions were studied:

$$^{14}_{7} + {}_{0}n \rightarrow {}^{14}_{6}\mathrm{C} + {}^{1}_{1}\mathrm{H}, \qquad (1)$$

$$^{10}_{5}\mathrm{B} + {}^{1}_{0}n \rightarrow {}^{7}_{3}\mathrm{Li}^* + {}^{4}_{2}\mathrm{He}, \qquad (2)$$

where ${}^{7}_{3}\mathrm{Li}^*$ denotes the ${}^{7}_{3}\mathrm{Li}$ state of 0·45 MeV. excitation energy. By a careful examination of the tracks, it is possible to discriminate those produced in the disintegrations of boron or nitrogen from the background tracks due to gas atoms (hydrogen or helium atoms) set in motion by fast neutrons. The distributions of the total ranges are given in the histograms Figs. 1 and 2.

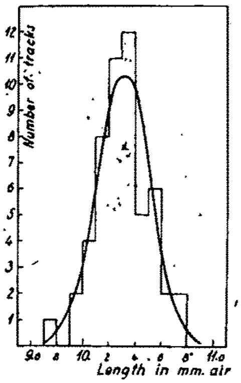

Fig. 1. DISTRIBUTION OF TOTAL RANGES OF 54 TRACKS PRODUCED BY THE REACTION ^{14}N (n,p) C^{14}

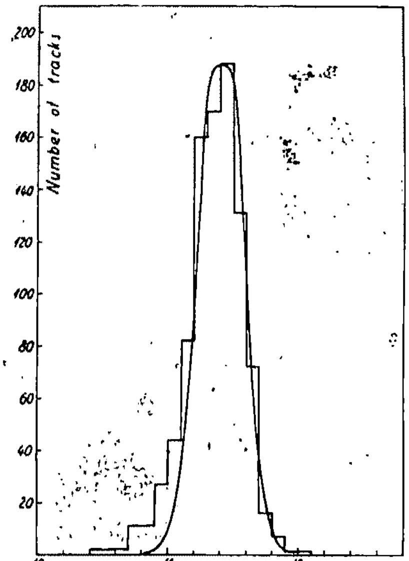

Fig. 2. DISTRIBUTION OF TOTAL RANGES OF 926 TRACKS PRODUCED BY THE REACTION ^{10}B (n,α) ^{7}Li

The range distribution $W(R)$ in Fig. 1, corresponding to reaction (1), can be fitted to a Gaussian curve

$$W(R) = \frac{1}{\sqrt{2\pi}\,\Omega} \exp - \frac{(R - R_0)^2}{2\Omega^2}, \qquad (3)$$

and leads to a straggling coefficient $\Omega = 0{\cdot}20$ mm. The mean ranges of the protons and the ^{14}C particles are found to be 10·0 and 0·3 mm. of air at N.P.T., respectively, and since the contribution of ^{14}C to the straggling must be expected to be small, we find for the relative straggling coefficient of the protons

$$\left(\frac{\Omega}{R_0}\right)_H = 0{\cdot}020.$$

This result is in good agreement with the theory[2] according to which the straggling for protons of not too short range, where the effect is primarily due to electronic collisions, should just be about 2 per cent, approximately independent of range and stopping material.

The range distribution in Fig. 2 could not be represented by a simple Gaussian curve, since the histogram is distinctly unsymmetrical. This circumstance may be taken as an indication that nuclear collisions contribute appreciably to the straggling effect. In fact, in this case, the possibility of the particle losing a comparatively large part of its energy in a single encounter may give rise to a dissymmetry in the straggling curve of the type found.

The straggling curve may, in such cases, be interpreted as an approximately Gaussian peak with a tail extending considerably beyond the peak towards smaller R-values[3]. For the measurements shown in Fig. 2, representing the distribution of total ranges for a helium and a lithium particle combined, the tail is estimated to contain about 15 per cent of the tracks. (The tail is somewhat depressed, since tracks containing side branches of more than 0·2 mm. of normal air were excluded from the statistics.)

The best fit to the Gaussian peak corresponds to a width Ω^* of 0·16 mm., leading to a relative straggling coefficient of

$$\frac{\Omega^*}{R_0} = 0{\cdot}014.$$

Under the experimental conditions it was not possible to ascertain at what point of the track the boron disintegration takes place, and the individual straggling coefficients for the helium and lithium particles cannot, therefore, be obtained. If the two relative straggling coefficients were equal, a simple calculation gives about 0·02 for each when taking into account that the mean ranges are estimated to be 7·0 and 4·35 mm. for the helium and the lithium particles[4], respectively. This result obviously implies that, for one of the particles, the relative straggling is at least about 2 per cent. The theoretical estimates of the contribution of electronic collisions to the straggling give, however, only about 1 per cent and $\frac{3}{4}$ per cent for α-particles and ^{7}Li nuclei, respectively.

Whereas the straggling of the protons by reaction (1) could be accounted for by electronic collisions, it thus appears that the width as well as the shape of the experimental straggling curve, corresponding to the process (2), give evidence of an essential contribution of nuclear collisions. This circumstance is in accordance with general theoretical arguments, according to which the relative importance of nuclear collisions on stopping and straggling increases rapidly with increasing charge and decreasing velocity of the penetrating particle. Further measurements to improve the analysis of the range distributions are going on, and it is hoped thereby to obtain more detailed estimates regarding the straggling effect of nuclear collisions.

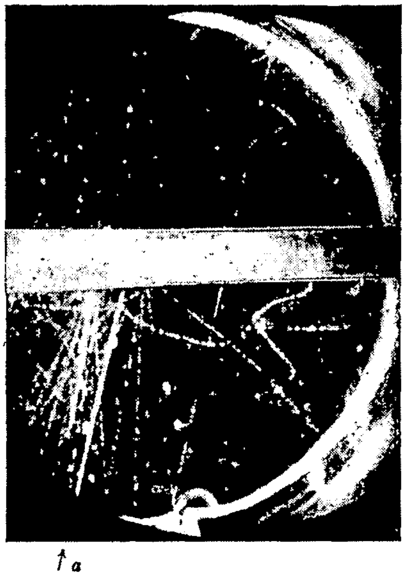
A Doubly Charged Cosmic Ray Particle

AMONG more than a thousand stereoscopic counter-controlled cloud chamber photographs of mesons which we have obtained during the past six months while studying the scattering of mesons of different energies in lead plates, we have obtained the photograph reproduced herewith. Each one of the stereoscopic cameras made an angle of 22½° with the normal to the chamber. The chamber was triggered by a triple coincidence Geiger–Müller counter system with 25 cm. of lead below the chamber and above the lowest counter, so at least one of the particles must penetrate 25 cm. of lead. There was no lead on the top of the chamber. The usual argon–alcohol mixture was used in the chamber.



HEAVILY IONIZING DOUBLY CHARGED PARTICLE EJECTED FROM THE LEAD PLATE BY A NEUTRAL PARTICLE AND ACCOMPANIED BY ELECTRONS AND MESONS

The photograph reproduced and its stereoscopic partner show several cascades produced by electrons in the 2-cm. lead plate inside the chamber, accompanied by penetrating particles which have gone through the plate without appreciable deflexion. They also contain a thick track (a) which emerges from the bottom of the lead plate and is produced by a particle accompanying the electrons and the penetrating particles.

A careful stereoscopic re-projection of this thick track through the lead plate into the top of the chamber shows that it would lie just within the illuminated region near the lead plate, and would thus be visible if it were a heavily ionizing particle going right through the lead plate. The heavily ionizing particle therefore appears to have been produced by a non-ionizing ray entering the top plate and accompanying the other electrons and mesons in the shower. Careful consideration shows that the heavily ionizing particle is probably doubly charged.

The heavy track shows four delta-rays along its length, of which two have ranges in air of 0·75 cm.–1 cm. From this it can be calculated that their energy must be between 20 and 25 keV., and hence they must have a velocity v approximately equal to 0·3 c, c being the velocity of light. The heavy track must be due to a particle of mass large compared with that of an electron. Hence the minimum velocity of the particle must be $v/2 \cos \theta$, θ being the angle which the delta-ray makes with the heavy track. This angle is 45° in the present instance. It follows that the velocity of the particle must be at least $0{\cdot}21\ c$, and so the density of ionization of this particle could be at most eleven times the minimum density of ionization if it were singly charged. The density of ionization of a doubly charged particle of the same velocity would be four times the above value, namely, forty-four times the minimum. The average density at the end of the range of the delta-ray track ($v = 0{\cdot}1\ c$) would be of the order of forty to fifty times the minimum density of ionization, and from the present photograph and other enlargements of the track it can be seen that the density of the main track is at least of the same order as that of the delta-rays, namely, forty to fifty times minimum, which is about the same as that of a doubly charged particle. Therefore, we conclude that the heavily ionizing particle must be doubly charged.

It is possible that it is an α-particle thrown out of an explosion process; if it were so, its energy would be 80×10^6 eV. Since the origin of this particle is in the back portion of the lead plate, and since it is coming towards us, it is possible that the other explosion particles, if any, have gone to the back of the chamber and so out of the field of view. The particle might also be a doubly charged proton[1]. The importance of the photograph is, however, that it shows that a doubly charged particle has been ejected by a neutral particle accompanying a shower of electrons and mesons.

It must be noted that similar heavy tracks have been obtained by others[2,3]. But it is remarkable that this photograph of a rare event was obtained at sea-level in a total of only a thousand pictures. The other small thick track to the left of the particle (*a*) is possibly a superposition of two tracks in the direction of the camera. Unfortunately, this track in the right-hand stereophotograph has been completely obscured by the bright background.

I have great pleasure in acknowledging my thanks to Prof. H. J. Bhabha for his guidance and suggestions on the analysis of the photograph.

Interpretation of Data from Electrical Resistivity Geophysical Surveys

Electrical resistivity surveys are all based on the method of Wenner[1]. A current, I, is passed into the earth through one point electrode and returns to the apparatus through a second. The potential difference between two points on the earth's surface, V, is measured. Let

$$R = V/I. \tag{1}$$

Then R can be related to the resistivity of the earth and the electrode spacing. Usually the four electrodes used are spaced in a straight line, and frequently a symmetrical arrangement is used. If the distance between the current electrodes is $2a$ and between the potential electrodes is $2\alpha a$ for a symmetrical arrangement, it is easily shown[2] that, for a homogeneous earth, the resistivity ρ is given by

$$\rho = \pi a \frac{(1-\alpha^2)}{2\alpha} R. \tag{2}$$

If the earth is not homogeneous, the value of ρ obtained from (2) will vary with a. This variation will be related to the nature of the earth, and hence the usefulness of the method.

The theory of the variation of ρ for different earth structures has been considered by many authors. The general conclusion is that the mathematical treatment is excessively complex for any but the simplest structures. Further, the number of parameters entering into the equation becomes large, and this alone would make the interpretation of practical curves difficult. The case of an earth composed of parallel layers of homogeneous material is of especial interest as other geophysical methods are not suitable. For this case it has been shown[2,3] that the more complex earths can be approximated to by the use of the solution of the two-layer case.

For this case, Hummel[2] has shown that

$$\frac{\rho}{\rho_1} = 1 + \sum_{n=1}^{\infty} k^n \left\{ \frac{1/\alpha + 1}{\sqrt{1 + \left(\frac{2nh}{a(1-\alpha)}\right)^2}} - \frac{1/\alpha - 1}{\sqrt{1 + \left(\frac{2nh}{a(1+\alpha)}\right)^2}} \right\}, \tag{3}$$

where $k = (\rho_2 - \rho_1)/(\rho_2 + \rho_1)$ = reflexion factor; (4)

and h is the thickness of the upper layer of resistivity ρ_1 and the lower layer has a resistivity ρ_2 and an infinite depth. This curve has no maximum or minimum and so it is difficult to fit it to field results.

A method of applying (3) to practical cases has been suggested by Tagg[3], but this involves considerable calculation on each occasion it is used. On the suggestion of Prof. L. S. Palmer, the point of inflexion of (3) was found as a function of k and α. This method was abandoned because of the difficulty in calculating the point of inflexion and also the difficulty of obtaining it from experimental data.

Further investigation suggested that a graphical method of solution was possible. Referring to (3), it will be seen that all curves for a given k and α can be reduced to the same form by plotting ρ/ρ_1 against a/h. As h is the unknown on which most interest is centred, this cannot be done directly. If, however, a set of curves of $\log \rho/\rho_1$ against $\log a/h$ for different values of k and the constant α (universal curves) is prepared, these can be used to interpret logarithmic plots of the experimental results. The logarithmic plot will be identical with the universal curve with the same value of k except that the axes will be displaced by $-\log h$ and $-\log \rho_1$ from the $\log \rho/\rho_1$ and $\log a/h$ axes respectively.

By adopting a standard scale for the graphs and working with a constant α, the universal curves can be plotted on transparent material and the axes marked. The transparency is then fitted over the experimental graph and the position of the axes of the universal curves give h and ρ_1 directly, and k is found from the actual universal curve used. The computation of universal curves is simplified by using the tables of Roman[4].

The universal curves can be used for multilayer earths to the same degree of approximation as the methods discussed by Hummel and Tagg, and, in fact, this approximation can be rapidly and easily accomplished.

This method has been used on four experimental curves obtained by L. S. Palmer. In one case, bore-hole data were available and the result was in excellent agreement for the depth of the layer.

Annealing of Glass

S. M. Cox[1] has considered the departure from the 'Maxwellian' law of the annealing-rate in glass. He attributes that part of the discrepancy which cannot be accounted for on the basis of a progressively changing viscosity to changes in the equilibrium condition of the glass under the action of the stresses present. An expression for the rate of release of stress is obtained, based on a theoretical derivation of the laws governing these changes and the rate of approach to equilibrium. Unfortunately, in his brief account only the final expression is given, so that it is not possible to comment on the derivation, nor on the extent to which a fit with Morey's experimental results provides a confirmation of the theory.

However, these 'approaches to an equilibrium condition in the presence of stresses are well known as observed phenomena, appearing as the 'delayed elastic effects' in ordinary experiments. Under constant stress, glass and many other substances obey the following expression :

$$\text{strain} = a + bt + c.f(t),$$

where a, b, c are constants proportional to the stress and dependent upon the temperature, composition, etc. The three terms represent respectively the instantaneous reversible elastic strain, the irreversible purely viscous flow at constant rate, and the reversible delayed elastic strain. The function $c.f(t)$ has the value 0 at $t = 0$ and c at $t = \infty$.

It is scarcely surprising that the rate of release of stress during annealing is not 'Maxwellian', when it is remembered that Maxwell's equation of visco-elasticity (which suggests the 'Maxwellian' or exponential rate of release of stress) leads to an expression for the behaviour under constant stress which does not include any delayed elastic effect, namely : $\text{strain} = a + bt$. The original theory of annealing, in fact, considered only relaxation of stress through the mechanism of viscous flow. The representation of the more complicated behaviour of real materials has, however, been extensively discussed (see, for example, Alfrey and Doty[2]), and it is possible to derive a theoretical 'stress release' curve from any 'creep' curve obtained under constant applied stress, and vice versa.

I have recently shown[3], by considering the mechanism of the annealing process and the experimental data on the delayed elastic effects in glass, that it would be possible on this basis to account for the discrepancies remaining in the theory of annealing. I pointed out also that a further complication existed, since the rate of release of stress must depend partly on the form of the previous cooling schedule for the glass, during which partially developed delayed elastic strains might have been 'frozen-in'. Experimental data in this field are at present insufficient for a quantitative formulation of the annealing laws.

The description of the phenomena proposed by Mr. Cox appears to be analogous to the explanation of delayed elasticity under uniform compression described by Frenkel[4]. It is of interest that this explanation, and apparently Mr. Cox's theory, both lead to a single exponential term of the form $\{1 - \exp(-t/\tau)\}$ for $f(t)$, although the experimental results on the ordinary delayed elastic effects can only be represented as the sum of a number of such terms with differing coefficients and 'relaxation times'. For glass the function is probably of the form $\{1 - \exp(-\sqrt{t/\tau})\}$, which implies a continuous distribution of such terms. There are other discrepancies between this theory and the experimental facts, and added complications in considering stresses, such as shear stresses, which do not involve a change in volume. It is more satisfactory to look to the existing (although incomplete) experimental data for an explanation of the anomalies in the annealing process.

[4] Frenkel, J., "Kinetic Theory of Liquids" (Oxford, 1946).

It is true that such theoretical work on problems associated with annealing of glass must be of a tentative nature until adequately supported by experiments, but its value lies in that it provides guidance for the design and interpretation of experiments. Without such guidance there is, for example, confusion between delayed elasticity and viscosity change with time ; the influence of stabilization with respect to temperature is also enigmatical. In Dr. Jones's own experiments[1] no attempt was made to stabilize the glass with respect to temperature. His results are particularly interesting for this very reason, because in his bending test—involving an averaged effect for both tension and compression together—there are theoretical grounds for supposing concurrent temperature stabilization to be without influence. Dr. Jones, in finding this experimentally, erroneously concludes the effect to be absent.

A feature which reduces the usefulness of the experimental results is that glasses of different composition have been used, and unfortunately there is a sparsity of experimental work on 'dilute' silica glasses—the study of which is most likely to be amenable to theoretical treatment.

Failure of Adrenal Cortical Extracts to Cause Lysis of Living Lymphocytes *in vitro*

In a series of papers by Dougherty, White and Chase, it has been claimed that the rate of lymphoid tissue dissolution is under the control of the adrenal cortex[1–5], and that injections of pituitary adrenocorticotropic hormone or adrenal cortical extract accelerate this dissolution and release antibody globulin which, it has been claimed by themselves[6,2,7,4,5] and by other workers[8,9] is present in the lymphocytes. The evidence adduced by Dougherty, White and Chase in support of this contention was the histological finding of cellular destruction and increased phagocytic activity in the lymphoid organs, and the reduction of weight of these organs, which they[10] and others[11–14] had shown to follow such injections. The present work was undertaken to investigate by quantitative methods the action of adrenal cortical extracts on lymphocytes, and to determine whether any direct lytic effect could be demonstrated.

Adult albino rats were bled from the heart into a sterile paraffined syringe, the blood allowed to clot in a 'Pyrex' tube and the serum removed. Next day the inguinal lymph nodes of the animal were removed with aseptic precautions; and macerated in sterile Simms'[15] saline solution containing 5 units of crystalline sodium penicillin per ml. By this means a suspension of cells comprising approximately 96 per cent lymphocytes was obtained. The suspension was centrifuged in a sterile tube at a slow speed to throw down the cells and to separate fat and cell fragments. The supernatant was discarded and replaced with a nutrient fluid consisting of equal volumes of the homologous serum and Simms' saline solution, the latter containing penicillin (5 units/ml.), and the appropriate dilution of the hormone preparation under test. After mixing, the tubes were incubated at 37° C. for 8–12 hours in an atmosphere of 95 per cent oxygen and 5 per cent carbon dioxide. Sterile samples were withdrawn at intervals after careful resuspension of the cells, and the cell population enumerated. Control tubes containing hormone inactivated by prolonged heating, and others of serum and saline only, were set up for each experiment.

Two adrenal cortical preparations were employed: 'Eschatin' (Parke Davis and Co., Ltd.) (for which I am indebted to Dr. J. Stanley White of Parke Davis and Co.) and 'Eucortone' (Allen and Hanbury, Ltd.). In one series of experiments the hormone ('Eschatin') was added directly to the nutrient medium in concentrations ranging from 1 : 500 to 1 : 10,000. In another series the animal was given a large dose (1–2 ml.) of hormone ('Eschatin' or 'Eucortone') by intraperitoneal injection three hours before withdrawing blood for the preparation of serum.

The results were negative in all experiments but one. No significant diminution occurred in the number of lymphocytes in the suspensions in any of the tubes, except in one experiment in which heterologous and not homologous serum was employed. In this case the regression of lymphocyte density on time did show that a significant lysis of cells had occurred, even though many of the surviving cells exhibited active movements at the end of the experiment.

It was concluded that if adrenal cortical extract does act on the lymphocyte, its action is not directly to cause lysis of the cell. The recent reports of Eisen *et al.*[16] and of Stoerk, John and Eisen[17], that the adrenal cortex does not influence the level of ci culating antibody or the turnover of serum protei are also evidence against the conception of adren cortical control of antibody release from lymphocyt by causing lysis of the antibody-bearing cells.

The reduction in weight of the lymphoid organ reported by the investigators already mentione above[11–14] to follow injections of pituitary adren corticotropic hormone or adrenal cortical extrac or the similar reduction in the weight of these organ occurring in the course of the alarm reaction o Selye[18,19], is explicable on the basis that the physic logical action of the adrenal cortex on the lymphoi organs is not so much to cause lysis of adult cells a to control the maturation and mitotic-rate of youn lymphocytes. However, with very severe sub-letha stimuli the effect on the dividing cells may be s marked that actual cell destruction occurs, especiall in the thymus, where the mitotic-rate is high.

Formation of Oxime-Nitrogen in *Torula*-Yeast Fed with Potassium Nitrate

The question of the formation of hydroxylamin and oxime as intermediate products in the fixatio of nitrogen has been under investigation for man years[1]. Formation of oxime-nitrogen has bee established both with Azotobacters and higher plant when nitrate has formed the source of nitroge nutrition. Examination of oxime-nitrogen is no easy because of its small amount and because th methods of analysis are not satisfactory, in particular, if the solutions to be examined are not quite colourles and clear.

In this Laboratory, synthesis of amino-acids wa recently studied with low-nitrogen yeast (*Torula utilis*) by suspending yeast in ammonium sulphat solution (Roine[2]). A great increase was then noted in the soluble nitrogen' of yeast due to amino-dicarboxylic acids and their amides as well as to alanine. Roine was not able to find other amino-acids; accordingly, his investigation supports the view that the amino-dicarboxylic acids are formed as primary amino-acids in accordance with the findings regarding nitrogen fixation.

Recently, we have carried out corresponding experiments by suspending low-nitrogen yeast (*Torula utilis*) in a 1·5 per cent solution of potassium nitrate. The increase of amino-dicarboxylic acids, their amides, and alanine in yeast was similar to that with ammonium sulphate feeding. Besides, a very rapid formation of oxime-nitrogen was observed. The maximum amount of oxime-nitrogen was attained in about ten minutes, after which a drop followed. The procedure employed was as follows: low-nitrogen yeast was suspended in nutrient solution free from sources of nitrogen and carbon, potassium nitrate was added to a concentration of 1·5 per cent and a vigorous current of air was passed through the suspension. Samples taken at different intervals were put in centrifuge tubes placed in ice, centrifuged and washed once with ice-cold water. Twice the volume of trichloracetic acid (8 per cent) was added and the acid suspensions were allowed to stand in an ice-box for 24 hours, centrifuged, filtered through a Jena glass filter and the clear solution was used for determinations. Centrifugation and washing the yeast took about twenty minutes; decomposition of oxime possibly occurred during this time. The quantities of oxime-nitrogen found may thus represent only a part of the actual amount. Oxime-nitrogen was determined by hydrolysing with 3 N sulphuric acid for six hours in a boiling water-bath and determining hydroxylamine according to Blom[3]. The solutions were colourless and transparent, and determination of the red colour formed was easy. The intensity of the colour was measured with a photo-electric colorimeter. The accompanying table gives the results.

AMOUNTS OF OXIME-NITROGEN IN μGM. PER 100 GM. FRESH YEAST

No. of expt.	Time (min.) 0	5	10	15	20	30	60	240	Source of nitrogen and treatment of samples
	With low-nitrogen yeast								
1*	0			+		+	0	0	Potassium nitrate. Extraction with trichloracetic acid
2	0			70		44	47	41	
4	0	31	280		80	0			
5	0	49	84		57	42			
3	0			0		0	0	0	Potassium nitrate. Extraction with water after freezing
6	0	0	0		0	0			Ammonium sulphate. Extraction with trichloracetic acid
	With normal yeast								
7	0	54	167		31				Potassium nitrate. Extraction with trichloracetic acid.

* Oxime-nitrogen shown qualitatively only.

A very small amount of free hydroxylamine was found in every experiment where oxime was noted. It might have originated from oxime in trichloracetic acid solution. Nitrite, hyponitrite and nitrohydroxylamic acid, which also give the colour reaction, are quantitatively destroyed during 6 hr. on boiling with 3 N sulphuric acid[4]. Accordingly, only hydroxylamine is determined by Blom's method.

The results show that the low-nitrogen yeast kept in nitrate solution always contained oxime-nitrogen (Expts. 1, 2, 4 and 5), whereas the same yeast in 1 per cent ammonium sulphate solution did not give even a trace of oxime-nitrogen (Expt. 6). Yeast with normal protein content (normal yeast) also forms oxime-nitrogen from nitrate (Expt. 7). In this respect there seemed to be no difference between normal and low-nitrogen yeasts. Some hydroxylamine was found in addition to oxime; this, however, may have originated from the oxime in the trichloracetic acid solution. Oxime-nitrogen in the table comprises both free hydroxylamine and that set free by sulphuric acid hydrolysis. In some experiments the low-nitrogen yeast suspended in nitrate solution was frozen and then extracted with water in an ice-box. No oxime-nitrogen could then be detected (Expt. 3), or at the most only traces. Accordingly, detection of oxime-nitrogen requires that the reduction be rapidly inhibited, as will happen when the sample is placed in trichloracetic acid solution.

Torula grows on the surface of agar with hydroxylamine as its sole source of nitrogen in concentrations up to 1 : 5,000, the highest concentrations after adaptation. In the nutrient solution *Torula* did not grow in the hydroxylamine concentrations used. With nitrohydroxylamic acid *Torula* grows well also in solutions after an incubation period of about 20 hours. Some hydroxylamine is then formed. The growth depends probably on the formation of nitrite from nitrohydroxylamic acid.

Bacterial Hydrolysis and Utilization of Polysaccharide-like Substances ('Mucin') in Saliva

AMONG the very heterogeneous bacterial population of the mouth are to be found large numbers of organisms such as streptococci, staphylococci and lactobacilli, which require some source of fermentable carbohydrate from which to obtain energy for growth and to maintain their normal metabolic processes. It has generally been assumed that, in the mouth, food constituents such as starch, after breakdown by salivary amylase (ptyalin), or simple sugars, provide this source. The observations presented in a preliminary form here show that some groups of organisms in raw saliva are able to break down and make available the salivary mucins themselves.

The amount of glucosamine, estimated after acid hydrolysis of the saliva by the method of Elson and Morgan[1], was used to measure the amount of polysaccharide present. This criterion was chosen rather than more obvious ones, such as the amount of reducing sugar or the total amount of sugar determined by Sørensen and Haaguard's method[2], since such measurements would also include any carbohydrate food constituents, for example, starch and sucrose, which might be present in the samples; glucosamine is a well-recognized constituent of many polysaccharides, including those present in the saliva.

The amount of glucosamine remaining in five samples of raw, unstimulated saliva after they had been incubated for various times was determined (see

BACTERIAL UTILIZATION OF POLYSACCHARIDES ('MUCINS') IN SALIVA INCUBATED AT 37° C.

48	0·18	0·10	0·20	0·01	0·05
72	0·08	0·09	—	—	—

table). The rate of disappearance of glucosamine was, in fact, shown to be paralleled by that of both total sugar and reducing sugar, the latter being measured after acid hydrolysis.

The utilization of glucosamine was completely inhibited by bactericidal substances such as phenol, toluene, thymol and penicillin, or by heating to 100° for five minutes. There was partial inhibition by 1 per cent glucose or maltose, but not by powdered solid starch.

In the presence of the bactericides, a substance accumulated in some samples which reacted as N-acetyl glucosamine in the Morgan and Elson[3] test. This substance was diffusible through 'Cellophane' and its liberation was due to enzymes associated with the cellular material present in the saliva, and not to enzymes formed by the salivary glands. The relation of the observed hydrolysis of the polysaccharides to the breakdown of the 'blood group substances'[4,5,6] present in relatively high concentration in the saliva of 'secretors'[6] is of interest.

The significance of these observations in connexion with the well-known pathological conditions of the mouth is, of course, unknown; but it is clear that organisms in stagnation areas would be able to obtain considerable amounts of fermentable material by breaking down the salivary mucins.

I should like to express my thanks to Mr. A. Parkinson for his enthusiastic and competent technical assistance during the work.

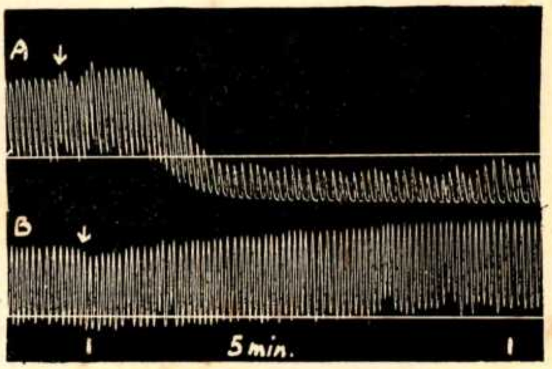
A Possible Relation Between the Action of Clover Juice on Isolated Muscle and 'Bloat' in Cattle

THE disturbance known as bloat, or hoven, in cattle arises through the inability of the animals to expel the gases formed in the rumen. Bloat can be expected when cattle graze young luscious clover or lucerne, but occasionally young grass can also cause the trouble.

A favoured view of the cause of bloat is that the muscles of the rumen wall lapse into relative immobility in the absence of adequate fibre in the diet and so fail to urge the gases to the œsophagus. Another view is that an allergic shock, resulting from some food constituent, may cause a spasm of the smooth muscle of the cardiac sphincter and so prevent escape of gas. In view of the possible association between bloat and rumen muscle activity, experiments were carried out to see if various herbage juices have any action on isolated smooth muscle.

Using rabbit intestine in Tyrode solution, twelve juices of legumes (*S* 100 white clover, wild white clover and lucerne) and nine grass juices were tested. One *S* 100 white clover was taken from a field in which two cows had just died through bloat. Very marked differences were obtained: the legume juices, when added in quantities of 0·7–2 ml. to a Tyrode bath of 55 ml. capacity, caused a rapid and very marked diminution in the amplitude and frequency of the gut movements. In some cases 2 ml. juice almost completely arrested the movements. At times this partial paralysis was accompanied by a relaxation of the muscle, as shown by a slight fall in the level of the tracing, or was occasionally preceded by a brief stimulation of movement.

Juices from two permanent pastures (one an irrigated pasture) gave effects resembling the clover, although the frequency of movements was not reduced. All other grass juices, from permanent grass and leys, gave quite different tracings. 1–2 ml. generally produced stimulation, but movements were occasionally uneven. The two types of effect are shown in the accompanying photograph.



A, CLOVER JUICE ; *B*, GRASS JUICE

Tests have shown it is unlikely that inorganic ions are responsible for the clover effect, and attempts are being made to separate the substance or substances responsible.

Heat only partially reduces the effect, and the loss may be caused by absorption of material on protein precipitated by the heating. The active substance passes through a 'Cellophane' membrane. An alkaloid fraction showed no effect.

Preliminary tests have indicated that the addition of very small quantities of adrenalin to muscle affected by clover juice can cause recovery after a brief period. This observation needs confirming, but it is of interest since injections of adrenalin are commonly given to treat bloat in cattle.

The peculiar effect of clover juice may, or may not, be of significance in bloat; but further work on the isolation of the substance or substances appears justified. If this is achieved, direct animal confirmatory tests will be possible.

PHARMACOLOGICAL ACTIVITIES IN DIFFERENT RODENT SPECIES OF *d*-TUBOCURARINE CHLORIDE AND THE DIMETHYL ETHER OF *d*-TUBOCURARINE IODIDE

By Dr. H. O. J. COLLIER and SHEILA K. PARIS
Pharmacological Laboratory
AND
Dr. L. I. WOOLF*
Research Laboratory, Allen and Hanburys, Ltd., Ware

THE molecule of *d*-tubocurarine chloride contains two phenolic hydroxy groups as well as two methoxy groups attached to the aromatic nucleus[1]. The hydroxy groups can be alkylated; when they are methylated, the resulting dimethyl ether differs in a striking way from *d*-tubocurarine chloride in its pharmacological properties[2].

d-Tubocurarine chloride was treated with two molecular equivalents of sodium hydroxide and then with two molecular equivalents of methyl iodide, all in methanol solution. The solution was evaporated, acetone added, and the precipitate repeatedly extracted with boiling acetone. The acetone solution on evaporation left the dimethyl ether of *l*-tubocurarine iodide as a white to pale yellow rystalline residue. This was recrystallized from thanol/ether. Analysis corresponded to the formula $_{40}H_{48}O_6N_2I_2.3H_2O$.

The effect of a curarizing substance on the neuromuscular junction can be considered from the points f view of both its intensity and its duration. Our xperiments show that the dimethyl ether of *l*-tubocurarine iodide differs markedly from *d*-tubourarine both in the intensity and the duration of ts effects on the neuromuscular junction in different pecies of rodents.

In the experiments reported here, the dimethyl ther of *d*-tubocurarine iodide has been compared vith *d*-tubocurarine in the following ways: (1) in he intact mouse, rat and rabbit; (2) in a preparation f the rat, under nembutal anæsthesia, similar to that f Raventós[3], in which the contractions of the rectus emoris muscle, in response to repeated condenser lischarges applied to its motor nerve at a rate of 5–50 per min., are recorded on smoked paper; 3) in the rat phrenic nerve-diaphragm preparation *n vitro*[4].

OMPARISON OF THE ACTION OF *d*-TUBOCURARINE CHLORIDE AND THE DIMETHYL ETHER OF *d*-TUBOCURARINE IODIDE IN THE INTACT MOUSE, RAT AND RABBIT. ADMINISTRATION BY THE INTRAVENOUS ROUTE

Substance	Test	Mouse		Rat*		Rabbit	
		Result (μgm./kgm.)	No. used	Result (μgm./kgm.)	No. used	Result (μgm./kgm.)	No. used
d-Tubocurarine	*ED*50 *LD*50	81·3 ± 7·2 200·6 ± 5·4	32 114	55·6 ± 3·7 100·9 ± 2·6	22 31	110–115 200–210	7 6
Dimethyl ether of *d*-tubocurarine iodide	*ED*50 *LD*50	120·0 ± 2·1 206·3 ± 5·65	42 46	13·6 ± 0·6 42·7 ± 2·1	25 22	9–12 30–33	6 6
Ratio of *ED*50 for the dimethyl ether compound to *d*-tubocurarine		0·7		4·1		9–13	
Ratio of durations of paralysis at 2/3 × *LD*50 for the dimethyl ether compound to *d*-tubocurarine		1		11		2–3	

* Young rats, weighing 35–65 gm.

All the results given are based on the weights of hydrated salts. Since *d*-tubocurarine chloride has the formula $C_{38}H_{44}O_6N_2Cl_2.5H_2O$, the ratio of molecular weights of the dimethyl ether of *d*-tubocurarine iodide to *d*-tubocurarine chloride is as 1·22 to 1.

In the intact animal the effect of curarizing substances is indicated by the inability of the animal to right itself after being turned on its back or side. The dose at which 50 per cent of animals are thus paralysed (*ED*50) may be regarded as an inverse measure of the intensity of this effect. The duration of the paralysing effect can be measured directly. The results of comparative experiments with the two substances in intact animals are summarized in the table, in which the values for *ED*50 and *LD*50 and their standard errors in the mouse and the rat were estimated by the method of Miller and Tainter[5].

In Fig. 1 the mean duration of paralysis in each species following the administration of various doses of *d*-tubocurarine or the dimethyl ether of *d*-tubocurarine iodide is plotted against the logarithm of the dose in μgm. per kgm. body-weight.

It is noteworthy that the duration of paralysis bears an approximately linear relationship to the logarithm of the dose over a considerable part of the dosage range in all three species and for both substances. It could, therefore, form the basis for a method of assay of either substance. As the slopes of the curves are a measure of increased duration of effect for unit increase of log-dosage, it can be seen that the slopes are inverse functions of the rates of elimination of the drugs, whether by destruction or excretion. Since the duration – log-dosage curves are not parallel, the durations of action of the two compounds have been compared in the table at the arbitrary dosage-level of two-thirds of the *LD*50.

In the Raventós preparation of the rat, the weight of the dimethyl ether of *d*-tubocurarine iodide required to reduce the tension of the muscular

---

* At present I.C.I. Research Fellow, Institute of Child Health, niversity of London.

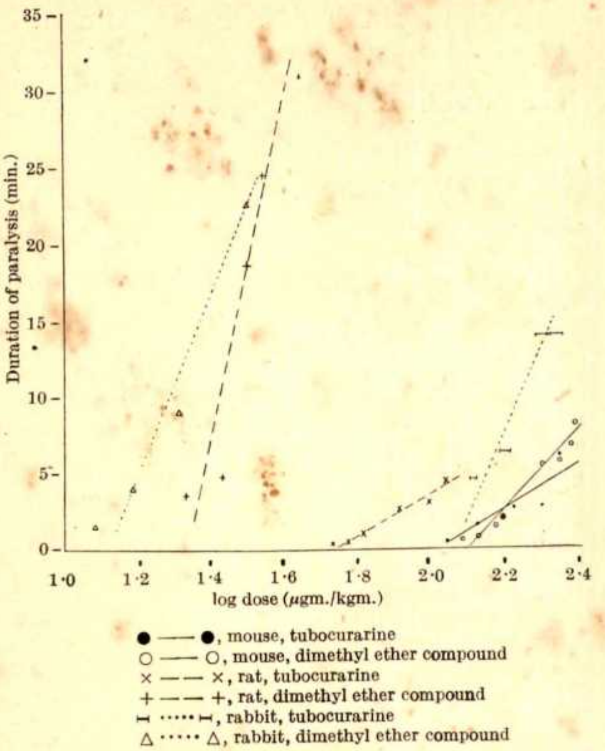

Fig. 1. DURATION OF PARALYSIS FOLLOWING INTRAVENOUS ADMINISTRATION OF *d*-TUBOCURARINE AND THE DIMETHYL ETHER OF *d*-TUBOCURARINE IN THE INTACT MOUSE, RAT AND RABBIT

response to a given extent was one-third to one-half that of *d*-tubocurarine, when each drug was administered by jugular cannula. Administration of either drug below a threshold-level of dosage (about 8 μgm. of *d*-tubocurarine and 3 μgm. of the other compound in a 200-gm. rat) causes no reduction of muscular tension. When, however, two sub-threshold doses of 3 μgm. of the dimethyl ether compound were given to a preparation at an interval of 15 min., the second dose reduced muscular tension by 95 per cent (roughly to the same extent as a single dose of 6 μgm.). The existence of this threshold is in keeping with the fact that the individual muscle fibre obeys the all-or-none law. The summation of the sub-liminal depression of neuromuscular transmission, so clearly seen with the dimethyl ether of *d*-tubocurarine iodide (Fig. 2), is also consistent with this law.

In rat preparations of this type the reduction of muscular tension following administration of the dimethyl ether of *d*-tubocurarine iodide lasts very considerably longer than that following the administration of *d*-tubocurarine, as is seen in Fig. 2. As the dosage of both drugs is raised, so the ratio of duration of effect of the dimethyl ether compound to that of *d*-tubocurarine increases (cf. Fig. 1). The prolonged existence of the former in the circulation is shown by the fact that, after full recovery from a preliminary effective dose of this substance, a second dose (or a dose of *d*-tubocurarine) given within the limits of one to two hours has a greatly increased effect (see above). A similar cumulative effect is produced by a preliminary dose of *d*-tubocurarine, but it is very transitory.

Ligation of the renal arteries and veins in the Raventós preparation prior to the administration of either substance, increases the duration of action of each drug but does not prevent recovery of the muscular contraction. Thus, in a typical preparation with the renal vessels ligatured, a recovery of 20 per cent of the original tension of muscular contraction occurred 10 min. after administration of 14 μgm. of *d*-tubocurarine, while in another similar preparation 20 per cent recovery occurred 58 min. after administration of 4 μgm. of the dimethyl ether compound.

Efforts have been made to estimate the urinary excretions of the dimethyl ether of *d*-tubocurarine iodide and *d*-tubocurarine in the intact rat. Preliminary results suggest that the former is excreted quantitatively, while *d*-tubocurarine is not.

Using the *in vitro* method of Chou[4], it was found that the dimethyl ether of *d*-tubocurarine iodide was 3·3 times as active as *d*-tubocurarine on the rat's phrenic nerve-diaphragm preparation.

In the rabbit, the intensity of action of the dimethyl ether of *d*-tubocurarine iodide is many times greater than that of *d*-tubocurarine (see table), while the slopes of the two duration curves in Fig. 1 are closely similar, indicating that the two substances are removed from their site of action at similar rates. This shows that the dimethyl ether compound has a greater specific action at the myoneural junction in this species. It is noteworthy that both rates of elimination are low, suggesting that the rabbit lacks the special mechanism of the rat (see below) for dealing with *d*-tubocurarine (cf. McIntyre[6]).

The greater specific myoneural effect of the dimethyl ether of *d*-tubocurarine iodide is again shown in the rat, though to a somewhat lesser extent than in the

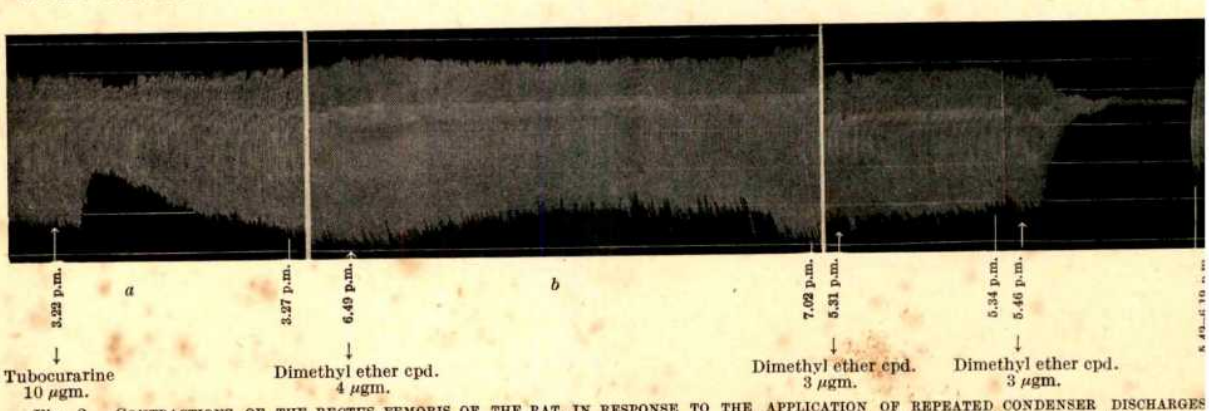

Fig. 2. CONTRACTIONS OF THE RECTUS FEMORIS OF THE RAT, IN RESPONSE TO THE APPLICATION OF REPEATED CONDENSER DISCHARGES TO ITS MOTOR NERVE, AFTER INTRAJUGULAR ADMINISTRATION OF (*a*) 10 μGM. OF *d*-TUBOCURARINE; (*b*) 4 μGM. OF THE DIMETHYL ETHER OF *d*-TUBOCURARINE IODIDE; AND (*c*) 3 μGM. OF THE DIMETHYL ETHER COMPOUND FOLLOWED 15 MIN. LATER BY A SECOND DOSE OF 3 μGM. IN (*c*) THE DRUM WAS STOPPED SEVERAL TIMES DURING THE RECOVERY PHASE

rabbit, by the *in vitro* experiments on the phrenic nerve-diaphragm preparation. In the intact mouse (see Fig. 1) it is seen that the myoneural junction is slightly less sensitive to the dimethyl ether compound than to *d*-tubocurarine, but the rate of elimination of the former is slightly less than that of the latter.

The fact that, in the rat *in vivo*, the duration of action of the dimethyl ether of *d*-tubocurarine iodide is many times greater than that of *d*-tubocurarine, whereas the intensity of its action is only about three times that of *d*-tubocurarine, indicates that the dimethyl ether compound is removed much more slowly than *d*-tubocurarine from its site of action in this species. That removal of both substances is partly effected by the kidneys is shown by the delayed recovery which follows ligation of the renal vessels. It is, however, clear that, in the rat with the kidneys eliminated, a mechanism exists for fairly rapid destruction or removal from the circulation of *d*-tubocurarine, but this mechanism does not operate, or operates very slowly, in the case of the other substance.

The dibenzyl and di-isopropyl ethers of *d*-tubocurarine iodide were prepared by methods similar to that described above. As judged by the *ED*50 and *LD*50 in the mouse, the dibenzyl compound possesses about one-third, and the di-isopropyl compound in preliminary experiments about one-half, of the activity of *d*-tubocurarine. In the rat and the rabbit, the dibenzyl compound exhibits about one-half the intensity of action of *d*-tubocurarine. In the rat, the dibenzyl ether gives no evidence of having an action more prolonged than that of *d*-tubocurarine at corresponding dosage-levels.

The dimethyl ether of *l*-bebeerine di-methochloride was prepared from *l*-bebeerine (from *Chondrodendrum platyphylum*) essentially by the method of King[1] (cf. Dutcher[2] and Brazil *et al.*[7]). The *ED*50 and *LD*50 of this compound in the mouse are approximately twice those of *d*-tubocurarine. The duration of paralysis in the mouse at two-thirds of the *LD*50 is approximately equivalent to that caused by *d*-tubocurarine at the same fraction of its *LD*50. In a Raventós preparation of the rat, 30 μgm. of the dimethyl ether of *l*-bebeerine dimethochloride reduced the tension of muscular contraction to the same extent as 10 μgm. of *d*-tubocurarine, but the effect of the bebeerine compound lasted four times as long. It is noteworthy that the dimethyl ether of *l*-bebeerine dimethochloride and its diastereoisomer, the dimethyl ether of *d*-tubocurarine iodide, both exhibit prolonged curarizing action in the rat as compared with *d*-tubocurarine.

We wish to express our thanks to the directors of Messrs. Allen and Hanburys, Ltd., for permission to publish this work; to Mr. C. J. Eastland for originally suggesting that the dimethyl ethers of *d*-tubocurarine and of *l*-bebeerine dimethochloride be synthesized and investigated; and also to Mr. S. H. Pegg and Miss P. B. Jacks for technical assistance in the pharmacological work.

THE FLOW OF GLACIERS

A JOINT meeting of the British Glaciological Society, the British Rheologists' Club, and the Institute of Metals, held at the Institute of Metals on April 29, had as its main object the bringing together of glaciologists and those physicists and metallurgists who are interested in the theoretical problems of glacier flow. The exchange of experience and ideas between these two groups was a most stimulating feature of the meeting.

The meeting was in two sections. In the first part, with Sir Arthur Smout in the chair, Mr. Gerald Seligman, president of the British Glaciological Society, presented a film illustrating the methods of glacier research in the field used by the Jungfraujoch Glaciological Research Party in 1937 and 1938. The principal aim was to trace the transition of the tiny snow crystals which accumulate at the top of the glacier, first into the compacted glacier snow called 'firn', and then into the larger crystals of glacier ice. To illustrate this transition, slides were shown of photomicrographs taken between crossed nicols in which the growth of the individual crystals could be clearly seen.

The audience was introduced to the terrain investigated by a series of slides which, besides illustrating its purely geographical features, left no doubt about the beauty of the scenery in which the expedition worked. The film showed the construction of the expedition's 'cold laboratory', a small room excavated out of the glacier ice near the summit of the Jungfraujoch. This laboratory remained at a temperature of −4° C. throughout the summer months, and it was here that much of the work on the growth of ice crystals was done. There were, in addition, experiments on the distribution of velocity at the surface of the glacier and on the walls of a tunnel cut into the ice.

Mr. Seligman also described the work of the expedition last summer on the same subject. He pointed out that very large crystals (10 cm. or more in diameter) are only found in the 'dead' (non-flowing) ice left behind in patches when a glacier recedes. In flowing ice the crystals are much smaller (up to 1–2 cm. diameter). In his view, time and radiation (heat and light) are the main factors influencing the crystal size. The increase in crystal size from the head of a glacier to the snout is due to the fact that the crystals in the lower parts of the glacier are older than those higher up. To support this, he showed graphs giving the crystal sizes at the centres of the snouts in eleven glaciers plotted first against the length of travel and secondly against the mean angle of the glacier slope. The influence of radiation was shown by the fact that in the vicinity of an electric lamp in an ice cave the crystals were abnormally large. It appeared from Mr. Seligman's remarks that both grain growth and work recrystallization play a part in determining the size of the ice crystals. The large size of the crystals in dead ice is a consequence of the former process, and the abnormally rapid growth of new crystals near the end of the Upper Grindelwald Glacier is an example of the latter.

For the second part of the meeting, Dr. Richard Seligman took the chair, and the discussion on the flow of ice was opened by Dr. M. F. Perutz, who gave a short summary of the current theories. The main feature of the movement of a glacier, he said, is that it does not move rigidly, but that the centre travels faster than the sides. Attempts made to treat the ice mathematically as a liquid of constant viscosity flowing in an evenly inclined channel have had some success, although there are also discrepancies. Lagally's development of Somigliana's theory has led to a relationship between the surface velocity at the centre of a glacier and its depth. Starting from the measured value of the velocity, the depth of the Pasterze in Austria, for example, has been calculated to be 280 m., a value confirmed by seismic soundings. In spite of this agreement, however, these theories have started from false premises, for ice is far from behaving as a liquid of constant viscosity. On the contrary, small differences in shear stress can produce large changes in velocity.

After referring to the importance of the large-scale thrust planes studied by Mr. W. V. Lewis, Dr. Perutz showed photographs taken by Dr. Winterhalter of Zurich of a thin sheet of ice placed between crossed nicols and loaded by sustained tension. The deformation of the constituent grains could be watched and there were indications of both gliding and mechanical twinning.

Dr. E. Orowan, who spoke next, took as his starting point the simplest laws of the theory of the plastic behaviour of crystalline bodies, and showed how many of the phenomena in glaciers, which at first sight appear to contradict common sense, can be understood from this point of view. Common sense in these matters is largely the accumulated experience of the behaviour of viscous liquids; but ice, like crystalline solids in general, is not a viscous but a plastic material. The flow of ice and that of viscous liquids corresponds to two distinct physical mechanisms and laws of irreversible deformation. However, the stress-strain relationship customarily used in engineering to describe the plastic behaviour of materials is not a complete description, because it omits time effects. The rate of change of strain with time under constant stress, that is, creep, is of primary importance in the flow of glaciers. Andrade has distinguished between two types of creep, the first dying away rapidly with time after the application of a stress, and the second being a permanent flow, the viscous creep. In glaciers, viscous creep seems the more significant part.

The idealized behaviour of ice on which Dr. Orowan bases his theory is that flow is negligible up to a certain critical stress, the yield stress. After that point a slight further increase of stress produces an extremely rapid increase of the rate of flow. The coefficients of viscosity 'measured' in experiments on glaciers are, he believes, of little physical significance. The three-dimensional nature of the stress system in large masses of ice is an important factor. Yielding depends on a critical value of the difference of two principal stresses being attained; pure hydrostatic tension or compression has no appreciable effect, contrary to a view often expressed by glaciologists.

The first simple problem Dr. Orowan discussed was that of a rectangular slab of ice resting on an inclined plane. Movement would be by shear in the lowest layer, and to each angle of slope would correspond one thickness of ice in plastic equilibrium. This implied that, when the ice reached a more steeply sloping part of the glacier bed, its thickness would be greater than the equilibrium thickness and this part of the ice would exert a pressure on the ice in front of it. This longitudinal pressure is the fundamental physical quantity in the flow; when it reaches a critical value, depending on the compressive yield stress of ice, longitudinal compression will occur. The observed thrust planes are a consequence of the compression; one cannot say exactly how they arise, but that they are a common phenomenon can be seen by attempting to clear away a fall of snow by pushing at it horizontally.

The thrust plane is usually the plane next to the bed of the glacier. However, at sills, that is, at places where there is a sudden fall in the level of the bed, other thrust planes become geometrically possible. This, combined with the fact that the thickness of the ice, and hence its pressure, is less at the lip of the sill, relieves the bed in its neighbourhood of wear. On the steeply sloping downhill side of the sill, on the other hand, conditions are such as to favour wear, for the sliding will be concentrated in the lowest layer of the ice. This is the explanation of the steps so often seen in glacier beds.

Dr. Orowan went on to discuss the problem of a tall column of ice standing on a rigid horizontal plane. If the column were sufficiently high and slender, its weight would cause flow to take place at the bottom, and it would subside to an equilibrium height. In the Greenland ice-cap conditions are different, because, owing to the great extent of the ice mass, the shear stress acting on the lower strata impedes the flow there and at the same time tends to initiate flow in the upper strata. By the use of a simple theory of the process, the yield stress of ice can be calculated from the known height and width of Greenland. The figure so calculated, which is of the order of 1 kgm./cm.^{2}, is in agreement with the results of laboratory experiments. A warning is necessary, however, because even a slight slope (1 : 300) would be sufficient to explain the spreading without invoking any other influence.

In the general discussion which followed, Mr. W. V. Lewis expressed the pleasure felt by glaciologists and those concerned with the land forms produced by glaciers at the interest that physicists are beginning to show in the subject. The uplifting of the thrust planes at the ends of glaciers would naturally cause less grinding to occur there than elsewhere, and this explains very satisfactorily why glaciers erode hollows in their beds. The formation of the lakes which are such a striking feature of Alpine scenery is now no longer so mysterious. Answering a question by Sir Geoffrey Taylor, Mr. Lewis expressed the opinion that the remarkably regular series of curves seen on the surface of the Mer de Glace, of which Dr Perutz had shown a slide, are the result of successive overthrusts which have been afterwards drawn out into curves by the general flow of the ice. Severa speakers referred to the slides Mr. Lewis presented which showed the striking way in which large rocks and other debris, which had originally fallen into the Bergschrund at the head of the glacier, are later brought up to the surface on thrust planes lower down, and Mr. Webster Smith suggested an experiment in which coloured objects were to be carried down underneath the glacier. Dr. Perutz, however thought that the slowness of the flow would make the experiment impossible. Mr. Webster Smith also emphasized the important influence of the varying hardness of the rocks constituting the glacier bed.

Dr. C. H. Desch drew a distinction between ic and metals by pointing out that, whereas ice expands on freezing, metals in general contract. That difference in behaviour should not be overlooked, and h suggested the use of bismuth at a few degrees below its melting point for laboratory experiments. Bismuth, although brittle under certain conditions, can be extruded and, in addition, expands on freezing; the analogy with ice is therefore complete.

Mr. C. Gurney took up this point later by saying that, whereas the effect of hydrostatic pressure on the melting point is of opposite sign for ice and metals, the effect of uniaxial compression is always to lower the melting point, even in metals.

In reply to Dr. G. W. Scott Blair's suggestion that ice might be found to behave more like a Bingham solid than a material obeying St. Venant's law of plasticity, Dr. Orowan said that the existence of transient creep is evidence that ice is not a Bingham solid; on the other hand, the existence of creep in general shows that it does not exactly obey St. Venant's law either.

Dr. Perutz had observed that in Alpine glaciers the crevasses were never more than about 30 m. deep, and Mr. W. H. Ward pointed out that this depth could be correlated in order of magnitude with the known yield stress of ice.

The discussion provided a happy illustration of the benefit of applying the simplest of physical reasoning to a science as yet largely empirical. In the words of one of the contributors, it was "better to think exactly with simplified ideas than to reason inexactly with complex ones". J. F. NYE

PROGRESS IN ARTIFICIAL ILLUMINATION

ALTHOUGH lip-service is commonly paid to the value of research, it is seldom that its direct benefits are so attractively displayed to the general public as has been done in the "Darkness into Daylight" Exhibition at the Science Museum, London, S.W.7. A visit to the Exhibition reminds one how very primitive were the means of artificial illumination only two centuries ago, while less than one hundred years ago the oil lamp was still the common form of lighting. We are all of us aware of the progress and achievements made during the past century. But how many realize that since only 1921 the efficiency of the ordinary 60-watt electric lamp has increased by 55 per cent while the cost has decreased by 75 per cent.

The exhibition has been organised by the Science Museum with the co-operation of the electrical industry of Britain, mainly to set forth the story of the development of electric lighting, but also to give a lead, and an example of the form of artificial illumination in the future.

A brief introductory section includes examples of some of the primitive forms of lighting used by early man—a hollow stone with fibre burning in animal fat, a wicker-work cage of fire-flies, sea-shell and oyster-shell lamps, a burning fish and a wick threaded into the body of a stormy-petrel are typical examples.

Passing from these primitive forms of lighting, a brief survey of the stages from the Middle Ages to the nineteenth century is made in a series of dioramas, showing the gradual changes brought about as candles and tallow-dipped rushes gave place to oil lamps and then in turn to the gas lamps of the last century. We can see the dawn of electric lighting with Swan's invention of 1878, its temporary eclipse by the Welsbach incandescent gas mantle and then the final triumph of the electric filament lamp.

The filament lamp has had a long career, and since its invention by Swan in 1878 and Edison in 1879 it has passed through innumerable stages of development. Swan had spent many years of research before he produced his carbon filament in 1878 and, incidentally, he laid the foundation stone of the rayon industry by his subsequent development of the squirted nitrocellulose filament in 1883. In stages, the carbon filament with its low efficiency of 2–3 lumens per watt gave way, first to the osmium filament, then to tantalum and finally to tungsten, when the difficulties of drawing tungsten wire had at last been overcome.

The tungsten-filament vacuum lamp had an efficiency nearly three times that of the carbon filament lamp, but to improve it still further a higher operating temperature was required. This resulted in an early blackening of the bulb, and although this could be overcome by filling the bulb with an inert gas, the heat lost by convection more than compensated for the gain until Langmuir's invention of the coiled filament in 1913. Still higher efficiencies were obtainable from the 'coiled-coil' filament invented soon after, but manufacturing difficulties prevented its introduction until 1934.

The efficiency of the modern filament lamp varies from the order of 12 lumens per watt for the smaller domestic sizes to about 25 lumens per watt for the largest projector lamps and, regarded as a source of artificial illumination, it must be agreed that the filament lamp is a remarkably cheap device. Indeed, as the visitor to the 'Darkness into Daylight' Exhibition is reminded at one stage, the average 60-watt lamp will burn for 1,000 hours at a cost, including that of the bulb, of only about 8*s.* 4*d.*; but were he by some whim or fancy to select candles as an alternative illuminant, he would need no less than 25,000 of them to give the same level of illumination for the same period and he would find himself faced with a bill of about £100!

As is perhaps inevitable, the accent of the Exhibition is on fluorescent lighting, and as one passes through this section one is forced to wonder whether the life of the filament lamp is doomed and whether it will eventually be replaced, like the oil lamp and the gas lamp before, by the low-pressure fluorescent tubes now being so widely used. Hitherto, these fluorescent lamps have only been available in lengths of 4 and 5 ft., but the recent announcement that 2-ft. tubes of 20- and 40-watt ratings will soon be introduced suggests a much wider application for domestic purposes. The fluorescence section of the Exhibition opens with a brief historical account of the discovery and developments which have contributed to the perfection of the modern tubes—the early observations of fluorescence, the Becquerel lamp of 1867 in which fluorescent materials were excited in a discharge tube, and the discovery in 1923 of a means of applying fluorescent materials to the walls of a mercury lamp. The stories of the search for a better colour spectrum, the first 'daylight' lamps and the finding of a single powder for producing a warm-white light are told by subsequent exhibits.

In imagination one is encouraged by a variety of fluorescent exhibits to regard such lamps as the lighting of the future. For industrial and commercial applications this indeed appears inevitable, but in spite of the three-fold improvement in efficiency and in spite of the three-fold increase in the average life, it still seems likely that the higher initial installation costs will reprieve the filament lamp for many years for ordinary domestic purposes.

In a brief review such as this, it is not possible to refer to the many stages of development in the various types of discharge lamps—the low-pressure sodium lamp with hot cathode, the low-, medium- and high-pressure mercury lamps, or to mention more than briefly the 5 kW. high-pressure water-cooled xenon arc now being shown to the public for the first time. Many of these developments are illustrated by exhibits and are described in greater detail with diagrams and photographs in the official handbook, "Darkness into Daylight", by W. T. O'Dea, which has been published in connexion with the exhibition (London: H.M. Stationery Office. 1*s*.).

The exhibition will remain open until September from 10 a.m. until 6 p.m. daily, and from 2.30 p.m. until 6 p.m. on Sundays; admission is free at all times.

PLANKTONIC COPEPODS AND HYDROCORALS OF THE JOHN MURRAY EXPEDITION

COLONEL SEYMOUR SEWELL'S account* of a large collection of free-swimming copepods from the Indian Ocean is an important critical study and a most valuable contribution to our knowledge of copepods in general.

In a previous paper (Sewell, 1920–32), seventeen species of free-swimming planktonic copepods were recorded from the northern part of the Indian Ocean, which up to that time were not known from any region other than the Atlantic Ocean or the Atlantic section of the Antarctic. The present collection contains twenty-one other species that so far have not been recorded beyond the Atlantic Ocean. As the author remarks, such a comparatively large number of deep-sea species that are common to the Atlantic and the Indian Ocean, but are at present unknown from any other region, indicates that there either is or has been a close connexion between the two regions. He has suggested (Sewell, 1940) that the explanation is to be found in the trend of the deep currents of the present day. He promises to deal later with the geographical distribution.

Well over two hundred species are recorded, with notes and remarks on most of them which are interesting and instructive. The new family Megacalanidæ is formed to include *Megacalanus*, *Bathycalanus* and *Brachycalanus*, all of which differ from the Calanidæ in several features and show a corresponding resemblance to the Centropagidæ.

Only one specimen of *Calanus finmarchicus* was found, a male, from the northern area of the Arabian Sea, 1,500–0 metres. It is rare in the Indian Ocean and it is suggested that its presence is explained by individuals being carried from the Atlantic Ocean round the Cape of Good Hope in the North Atlantic intermediate waters or the West Wind Drift, and then that they are caught up in the Sub-Polar Intermediate Current and so are carried northwards into the Arabian Sea.

Among the Sapphirinas it was found that *Sapphirina iris* was associated with the aggregated form of the salp *Pegea confederata*, some being inside. In this genus there were numerous cutaneous glands, opening on both dorsal and ventral aspects of the body in special positions in the different species. It is tempting to regard these as luminous organs, but the author does not wish to express an opinion on this point.

There is a long list of copepods with parasites both from surface-living and deep-dwelling species. This includes twenty-one species infested with the dinoflagellate *Blastodinium*. Comparing these with Chatton's seventeen species from the Mediterranean infested with *Blastodinium*, it is found that six are common to both lists.

Dr. Hjalmar Broch has found three new species in the four hydrocorals brought home by the John Murray Expedition to the Indian Ocean*. These include two new stylasters (*S.* (*Eustylaster*) *ramosus* and *S.* (*Eustylaster*) *lonchitis*), and one new *Crypthelia* (*C. clausa*), the fourth species being *Crypthelia stenopoma* Hickson and England. The two stylasters were from the Pemba Canal and the *Crypthelia* from the Maldives. It is interesting to note that in neither of these localities have Stylasteridæ been found before, and these reported localities of the John Murray Expedition are at the present day the most northerly localities of the Western Indian Ocean from which Stylasteridæ have as yet been found.

Another very interesting point is that whereas the two *Stylaster* species from the Pemba Canal have been collected in that zone of the bathymetrical region where the genus is known to be comparatively abundant in all seas, the localities of *Crypthelia* at the Maldives belong to the uppermost parts of its habitat, and its occurrence in these depths seems to be very scanty. The depth of 229 metres is the shallowest record of the genus, and *Crypthelia stenopoma* has hitherto only been taken in 1,300 metres or deeper in the Indo-Malayan Sea. *Stylaster ramosus* was abundant in two stations, its structure indicating that, like *Crypthelia stenopoma* and other Stylasteridæ, it is probably inhabited by commensal polychætes. The cirripede, *Pyrgoma*, is also commonly found in it.

THE ELECTRICITY GRID IN GREAT BRITAIN

THE twentieth and last annual report of th Central Electricity Board has recently bee published (Whitehead Morris, Ltd., 72–78 Fleet Street London, E.C.4. 1*s*. net). Just short of attaining it majority, the Board loses its identity in the infan British Electricity Authority, this sturdy infant inheriting the Grid system of some 150 generatin stations, capable of an output of nearly 12 millio kilowatts. Appropriately appearing at about th same time as this report is an interesting and informative paper dealing with the British grid syste ("Load Dispatching and the British Grid System"—A. R. Cooper, Institution of Electrical Engineer March 18, 1948), a paper which is wider in scop than its title might suggest.

Mr. Cooper describes first the long-term plannin associated with the extension of such a system planning which, as the Central Electricity Boar report makes clear, has had to yield to some exten to the stern demands of economic necessity, so that there is likely to be a serious shortage of plant for an indefinite number of years.

When assessing the need for future extensions, an estimate is required of the availability of existing plant, and some striking figures are given indicating that the technical advance in operating conditions has carried with it a general reduction in availability, so that breakdowns are more frequent on modern than on older plant. Leading sources of trouble are said to be turbine-blading failures due to vibration, and alternator rotor failures due to copper distortion, both of which are the subject of intensive research. Also responsible for reduced availability, as well as reduced output capacity, is the supply of unsuitable and low-grade fuels to the boiler plant, a war-time inheritance which persists in spite of the very great increase in the price of fuel.

Proceeding to the short-term planning associated with the daily operation of the Grid system, the paper reveals that the system was originally designed to operate as seven independent sections, and it was not until the load position in some areas had become very grave in 1939 that it was decided to try the experiment of operating the whole of the system in parallel. This operation was successful and has been continued ever since, though the possibility of sequential tripping of lines, accentuated by the existence of only two interconnectors between the north and south of Great Britain, has demanded careful consideration.

After an interesting description of the sequence of events in the planning of a single day's operation of this complex system, from the nerve centre at national control in constant communication with the seven area controls, the paper concludes with a brief review of future developments. The most significant changes foreseen are the introduction of the gas turbine for peak-load working, and of atomic energy for base-load generation. Here it is of interest to turn again to the report of the Central Electricity Board, which is able to cite the arrangements the Board has made for the installation of two 15,000 kW. gas turbine sets, at Dunston and Stretford respectively; though the application of atomic energy remains a subject for study, and a hope for the future.

R. W. Haywood

MOSSES AS SOIL INDICATORS

It is pleasing to see that the attention of foresters is being directed to the mosses as indicators of soil conditions. H. Watson, forest officer instructor at the Benmore Forest School, Argyll, has produced an attractive booklet introducing this subject (Forestry Commission Booklet No. 1. Woodland Mosses. London: H.M. Stationery Office, 1947. 2*s.* net).

The brief introductory account of the life-history of a moss is followed by descriptions of twelve species likely to be encountered in afforestation areas. The descriptions are accompanied by 'turf' photographs to show the habit of growth in mass, and photographs of single shoots to illustrate the more detailed growth-form and include the salient features by which the species may be recognized in the field. There are also notes on the soil conditions favoured, especially as regards the degree of humus decomposition and soil acidity, and brief reference is made to the suitability or otherwise of the soil conditions indicated for afforestation purposes.

The mosses constitute a fascinating group of plants of which all too little is known. Many of them, after a little experience, can be recognized in the field by the naked eye or with the use of a hand lens, and type specimens may be kept dry in packets and soaked out again when required. Forest officers should be in a position to extend considerably our knowledge of the soil conditions indicated by the presence of particular moss species along the lines of the present booklet; and the recent production by Johnson and Sons, Ltd., of Hendon, N.W.4, of Universal and Comparator Test-papers for the measurement of *p*H values to within 0·3 *p*H, provides a very simple method for estimating the soil acidity with some degree of exactitude. Information of this kind would not only be of value to practical foresters, but would also extend our knowledge of this group of plants.

The British Bryological Society has recently asked its members to make observations on mosses with particular reference to times of production of capsules and reproductive organs in different carefully recorded localities and altitudes. The time of capsule production offers no difficulty, and in many cases the reproductive stage may be recognized by the opening of the antheridial cups, as illustrated in the booklet for *Mnium hornum*. It is to be hoped that foresters will be attracted by this aspect of ecology and that Forestry Commission Booklet No. 1 will be followed by others.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, May 24

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Anniversary Meeting.

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5.30 p.m.—Mr. E. W. Gilbert: "The Boundaries of Local Government Areas".

Tuesday, May 25

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Dr. E. R. Leach: "Some Features of Social Structure among Sarawak Pagans".

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. Brinley Thomas: "Migration and the British Commonwealth".*

Society of Instrument Technology (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Annual General Meeting; Mr. J. K. Burkitt: "Proposed System in Instrumentation Symbols".

Wednesday, May 26

Society of Chemical Industry, Chemical Engineering Group (at the Waldorf Hotel, Aldwych, London, W.C.2), at 12 noon.—Annual General Meeting.

Royal Microscopical Society, Section of Industrial Microscopy (at B.M.A. House, Tavistock Square, London, W.C.1), at 6 p.m. —Dr. K. M. Greenland: "Principles of Interference Films used in Optical Instruments".

Thursday, May 27

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Edward Salisbury, F.R.S.: "The Royal Botanic Gardens, Kew".

Royal Statistical Society, Research Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. D. G. Champernowne: "Sampling Theory Applied to Autoregressive Sequences".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. A. Gouge: The 36th Wilbur Wright Memorial Lecture.

Friday, May 28

Society of Chemical Industry, Food Group (joint meeting with the Royal Sanitary Institute, at the Royal Hall, Ripon Road, Harrogate), at 10 a.m.—Discussion on "The Cleaning and Sterilizing of Plant in the Food and Drink Industry" (to be opened by Dr. E. B. Hughes).

Institute of Physics, Electronics Group (joint meeting with the Industrial Spectroscopic Group, at 47 Belgrave Square, London, S.W.1), at 2.30 p.m.—Discussion on "The Application of Electron-Multipliers to Spectroscopy".

Chemical Society (in the Washington Singer Laboratories, Prince of Wales Road, Exeter), at 4.30 p.m.—Prof. M. Stacey: "Advances in Immunochemistry".

British Institution of Radio Engineers, Midland Section (at the Technical College, The Butts, Coventry), at 6.30 p.m.—Mr. G. L. Hamburger: "An Automatic A.F. Response Curve Tracer".

Chemical Society (joint meeting with the Werner Society, in the Department of Chemistry, Trinity College, Dublin), at 7.45 p.m.—Dr. A. E. Gilliam: "Absorption Spectra as Chemical Tools".

Saturday, May 29

Biochemical Society (in the Department of Biochemistry, University Museum, Oxford), at 1 p.m.—Scientific Papers.

British Psychological Society, Social Psychology Section (at the Tavistock Institute of Human Relations, 2 Beaumont Street, London, W.1), at 3 p.m.—"Social Change as a Problem for Social Psychology".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Provincial Specialist Advisory Officers and Assistant Advisory Officers in soil chemistry, the chemistry of animal nutrition, entomology, plant pathology and bacteriology—The Secretary, Ministry of Agriculture and Fisheries, 1–4 Cambridge Terrace, London, N.W.1, endorsed 'N.A.A.S.' (May 29).

Senior Laboratory Technician (male)—The Medical Superintendent, Glamorgan County Mental Hospital, Bridgend, Glam., endorsed 'Laboratory Technician' (May 29).

Lecturer in Mechanical Engineering, and a Teacher of Engineering Drawing—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (May 29).

Bacteriologist—The Director, Freshwater Biological Association, Wray Castle, Ambleside, Westmorland (May 29).

Assistant Lecturer in Agricultural Chemistry—The Registrar, Wye College, Wye, Ashford, Kent (May 29).

Lecturer/Senior Lecturer in the Department of Anatomy—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (May 29).

Research Assistant to the Reader in Psychology in the Faculty of Education—The Registrar, The University, 46 North Bailey, Durham (May 29).

Senior Lecturer in Mathematics—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (May 29).

Agricultural Economist and Assistant Agricultural Economist—The Professor of Agricultural Economics, University of Reading, 7 Redlands Road, Reading (May 30).

Assistant Lecturer or Lecturer in the Department of Agriculture (Animal Husbandry)—The Registrar, University College of Wales, Aberystwyth (May 31).

Assistant Lecturer in Metallurgy (with special qualifications in ferrous process metallurgy)—The Registrar, The University, Manchester 13 (May 31).

Lecturer in Physiology—The Secretary and Registrar, The University, Bristol (June 1).

•Lecturer on the staff of the Royal Society's Computing Machine Laboratory, Department of Electrical Engineering—The Registrar, The University, Manchester 13 (June 4).

Readership in Biochemistry at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 9).

Readership in Biology at St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 14).

Occupational Psychology Research Officer, Department of Scientific and Industrial Research, Wellington—The Official Secretary, High Commissioner for New Zealand, 415 Strand, London, W.C.2 (June 15).

Readership in Mathematics at Bedford College—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 16).

Lecturer in Philosophy—The Registrar, University College, Cathays Park, Cardiff (June 21).

Senior Lecturer in Political Science, University of Melbourne—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (June 30).

Botanist (plant breeder) for research on the selection and breeding of *Hevea*, a Botanist for research and advisory work on botanical problems related to the cultivation of rubber, an Advisory Officer to undertake general agricultural advisory work, an Agricultural Engineer to investigate all aspects of the problem of mechanical cultivation in rubber, an Advisory Officer to undertake general advisory work in connexion with the cultivation of rubber by smallholders, and a Chemist to undergo a course of preliminary training in rubber latex technology and research at the Imperial Institute, at the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7.

Head of the National College for Heating, Ventilating, Refrigeration and Fan Engineering, a Lecturer in Fan Engineering, and a Lecturer in Heating and Ventilating Engineering—The Clerk to the Governors, Borough Polytechnic, Borough Road, London, S.E.1.

Assistant Research Officers (chemists and physical chemists), and Laboratory Assistants—The Director, British Paper and Board Industry Research Association, St. Winifred's Laboratories, Welcomes Road, Kenley, Surrey.

Technician in the Research Laboratory to work in the Department of Neurohistology—The Director of Research Laboratory, University of London Institute of Psychiatry, Maudsley Hospital Medical School, Denmark Hill, London, S.E.5.

Senior Laboratory Steward to take charge of the laboratories in the Chemistry Department—The Secretary, Woolwich Polytechnic, Woolwich, London, S.E.18.

Lecturer (Grade II) in the Department of Physics—The Clerk, Birkbeck College, Breams Buildings, London, E.C.4.

Head of the Textile Testing Department, an Organic Chemist, and Physicists (7)—The Acting Secretary, British Rayon Research Association, 58 Whitworth Street, Manchester 1.

Physical Chemists to build up a team to carry out fundamental research on the background physical chemistry of iron and steelmaking—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Man with good research experience for work on the physical chemistry of airborne dusts, especially those occurring in coal-mines—The Director, M.R.C. Pneumokoniosis Research Unit, Curran Works, Curran Road, Cardiff.

Librarian (with a good science degree, preferably in physics or chemistry)—The Director, British Boot, Shoe and Allied Trades Research Association, Satra House, Rockingham Road, Kettering.

Technician in the Pathological Department—The House Governor and Secretary, Queen Mary's Hospital for the East End, Stratford, London, E.15.

LOCAL GOVERNMENT IN BRITAIN

MORE than three years have now passed since the appearance of the White Paper of the Coalition Government on the reform of local government, and in presenting its second annual report the Local Government Boundary Commission, set up as a result of the sole recommendation of the 1945 report, has now reached the conclusion that in many areas of Britain—and these covering the great bulk of the population—the present powers and instructions of the Commission do not permit the formation of local government units as effective and convenient as they should be. In this report the Commission has chosen to set out its views and to detail recommendations which, if accepted, will require legislation and amendment of the 'General Principles' laid down by Parliament for its guidance. Much of the report is occupied by a discussion of the functions of local authorities, although the Commission has no jurisdiction in this aspect. Its experience has demonstrated the futility of considering functions and boundaries separately, just as it has shown the weakness of the original White Paper in refusing to contemplate any significant change in the existing structure of local government or the introduction of some form of regional development.

The first comment on a report which is characterized by realism and boldness, however strongly the application of some of its principles may be challenged in detail, is one of surprise that such a report could not have been produced in place of the original White Paper more than three years ago. There were then already available reports on local government reform from the Labour Party, the National Association of Local Government Officers and the Liberal Party, as well as numerous proposals from all the main associations of local authorities. The memorandum on local government areas, outlining the problems and opportunities of the Boundary Commission, issued over the signatures of Viscount Astor, Lord Simon and Mr. A. W. S. Burgess, the ex-Lord Mayors of Plymouth, Manchester and Bristol, and also several books which have been published since, ranging from Mr. G. D. H. Cole's "Local and Regional Government" (London : Cassell and Co., Ltd., 1947. Pp. xvi+295. 15*s*. net) to Mr. J. Blackburn's "Local Government Reform : the Two-Tier System" (Altrincham : J. Sherratt and Son, 1947. Pp. 146. 6*s*.), differ rather in the emphasis than in the character of their recommendations. In their analysis of the causes of weaknesses in local government and their criticism of the conditions for adequate reform, they foreshadow very closely the Commission's own recommendations, which might have been equally well forecast from a study of the numerous schemes for the reconstruction of the cities of Britain, or the planning studies of Herefordshire and other counties.

Agreement is now general on the need for far-reaching overhaul, and on the defects of the existing system and their causes ; but there is probably less prospect than in January 1945 of agreement on the nature of the changes required, or of ready acceptance of a scheme agreed by the majority. General reform is now even more likely to be contested hotly, while at the same time the deadlock now threatens the survival, not of the forms, but of the essence and spirit of self-government in local affairs. The multiplication of new public services and duties over the last thirty years and their concentration upon the major authorities to the detriment of the boroughs and district councils, with the tendency to remove altogether from the backward local authorities tasks which reformed authorities could well execute, is sapping the very foundations of local democracy upon which the effective working of democratic institutions upon a national scale depends.

The Boundary Commission's report is first and foremost an indictment of this neglect, of the policy of drift and of allowing piecemeal alteration of the responsibilities of local government authorities to distort the structure, so that it becomes less and less suitable for its task. The Commission has now, as already indicated, rightly decided that local government cannot be properly recast under the piecemeal terms of reference to which it is subject, and in the main the reasons given are endorsed by the large body of evidence already indicated.

At the outset, indeed, the Commission comments on the surprising adaptability of the system as a whole in practice, in spite of the fact that there has been no thorough-going overhaul of local government in Britain since the present system was established in 1888. The strain, however, is heavy, and is increased by various defects such as the disparity between individual counties and individual county boroughs in population and resources. This disparity is due partly to historical causes but mainly to the failure of adjustments of the local government structure to keep pace with changes in either population or functions; and the Commission observes that unless this defect in the system is remedied, Parliament may well hesitate to entrust to local authorities new functions which are in themselves entirely suitable for local administration.

Next, due partly to the weakness of the smaller units in all types of authorities, central control of local administration has increased and, if carried much further, will cut at the root of local government.

The report then reviews the types of local government units, discussing the relative merits of the 'one-tier' system, administered by a county borough council, or 'all-purpose' authority, and the 'two-tier' system, administered by county councils and county district councils. Finally, it recommends the creation of a new type of authority the area of which would form part of the county, but the scope of the functions of which would be intermediate between those of an 'all-purpose' authority and those of a 'minor-purpose' authority.

The broad outlines of the Commission's proposals and the general principles on which they are based have much in common with what has been advanced elsewhere, although most administrative authorities would regard the population limits suggested for the new county boroughs as too low for the autonomous conduct of some of the services, such as education and health, which it is proposed to entrust to them. In the memorandum on local government areas issued by the ex-Lord Mayors of Plymouth, Manchester and Bristol, the principles which it is suggested the Boundary Commission should bear in mind when determining the character of a major authority include the possession by each authority of the minimum standards of population, area and finance for the provision of services on an adequate and economic scale and for the employment of an efficient and specialized staff, and also the value of a satisfactory balance in each area of occupational classes and income groups. Each authority, too, should so far as possible form a satisfactory planning unit and should be based on the area of local political and civic consciousness.

The quantitative result of the Commission's proposals would be the division of England into sixty-seven new counties, none of which would have a population of less than 200,000. Twenty of these would be 'one-tier' counties, that is to say, large towns with precisely the same status as that of a county borough to-day. The remaining new counties would be administered on the two-tier system, with lesser authorities beneath them. The complete picture involves the elimination of seven counties and the insertion of five new two-tier counties, but three-quarters of the existing county boroughs would cease to be all-purpose authorities. On the other hand, there would be created initially sixty-three new county boroughs, authorities for most purposes; and while this may increase the acceptability of the scheme it introduces serious weaknesses and dangers in two-tier county administration. Even the importance of local interest can scarcely balance the reduction of the administrative unit for education and health to one of 60,000, and the attempt to please too many existing authorities, with disregard of administrative opinion, is unlikely entirely to avoid creating fresh jealousy and dissatisfaction between counties and expanding towns.

If this limit of 60,000 were raised to 100,000 or 150,000, a much more confident welcome might have been given to this scheme of reform, although it is still somewhat timid in dealing with the very difficult problems of the provincial conurbations, particularly in the face of such opposed views as those of Manchester or Liverpool and Sheffield or Bradford. It can also be urged further that at the other end the Commission has not faced squarely the real task of securing a more homogeneous lower tier of authorities with responsibilities which will attract the services and interest of the best elements in the local communities. Nor can it be said that the Commission's proposal to create an intermediate type of second-tier authority dealing with most purposes does anything to check the transfer to joint boards or nominated agencies of many functions which are suitable for democratic local control, but which require large administrative units.

It is the invasion, or erosion, of local government in this way that is the gravest danger to-day, and the great merits of the scheme and the careful study which the report undoubtedly merits should not be allowed to conceal that danger and the urgent need for dealing with it. It would undoubtedly have been better had either the Coalition Government or the present Government the courage and the time to reconstruct local government before the changes introduced by the recent education, health and planning Acts took effect. As it is, disappointment with the Commission's proposals as they affect individual towns or counties, or a possible feeling that the Commission has been excessively devoted to arbitrary standards of size, should not be allowed to stand in the way of a careful and objective study of what is a realistic and imaginative plan which calls for action without delay.

The opening chapters of Mr. G. H. D. Cole's book "Local and Regional Government" afford the student much assistance in appraising the Commission's proposals. Mr. Cole is inclined to eschew the intermediate unit, and urges that we need to create and to give real power to both larger and smaller units of administration than have been favoured by the trends of evolution of local government in Britain in recent years. In detail, for all his vision, he is sometimes unrealistic and discards the entities from which transition must be made; but the criticism that may justly be made of his own scheme does not affect the value of his book as a clear and interesting introduction to the problems of local government.

Mr. Cole himself describes his book as an attempt to influence the Boundary Commission in arriving at its plans for recasting local boundaries. It is much more correctly described as an important and valuable contribution to the formation of an intelligent public opinion capable of appraising the Commission's proposals impartially and securing prompt action upon them in so far as they meet the needs of democracy rather than suit the views and prejudices of local councillors and officials. His account of the growth of the existing system of local government is clear and concise, and the various approaches to local government are set out in a way which indicates not only the need for large-scale administrative units for some purposes, but also the immense possibilities in the preservation and recreation of really small communal units for other purposes closely related to the everyday lives of the people. The book is a useful contribution to the understanding of all the factors that are involved in the 'new towns' policy of the Government as well as of those that affect local government itself. It points to positive ways in which the community spirit might be revived and encouraged, and while giving a clear idea of what regionalism is, the different approaches to it and the dangers to be avoided, it should stimulate constructive and independent thinking about the nature of such authorities as well as of the technical and national boards dealing with water supply, power, transport and the like. Although, as already noted, the treatment of the problems of the great provincial cities or conurbations is not entirely adequate, at least the principles are indicated which could form the basis of more fundamental thinking about those problems.

Two of those main considerations emphasized by Mr. Cole are the immediate concern of scientific and technical workers and their professional associations. Recent debates on the Water Bill and the River Boards Bill have shown how technical development continues to call for the conduct of a number of essential public services under unified management over large areas. Water supply and drainage, sewage disposal, the control or prevention of flooding and pollution, fisheries, power supply and transport all present problems which may on occasion make impracticable for particular services the reconciliation of technical requirements with the adoption of areas of management that are suitable for other purposes, of regional or local government. The tendency may be unavoidable, but Mr. Cole's book should help the technician concerned to keep aware of the dangers inherent in such unification, and of the desirability of keeping it to the minimum consistent with genuine technical requirements.

Other services, such as gas and health and consultant services, may require to be co-ordinated and planned, but not administered, nationally; and it has already become apparent how much a professional body can contribute towards the solution of the problems involved in regional and local administration when national standards of service are to be observed and professional ideals and traditions maintained.

Primarily, the scientific and the technical worker is concerned with technical aspects of the problems which arise in local or in national government, and with seeing that technical requirements of efficiency are met. While, however, they must not be deflected from an impartial appraisal of the technical requirements by professional bias or sectional prejudice, they must be imaginatively alive to the human problems of government no less than to what is administratively practical. Something more than technical or professional competence is needed to resolve the deadlock in local government. Doubtless in time the British Institute of Management may be able to make its own contribution to the clear thinking that is essential, and especially by assisting in applying the lessons learnt under the stress of war in civil defence, the community centre and like fields.

Fundamentally, however, the second report of the Local Government Boundary Commission touches the scientific worker not so much because of its relation to special fields of professional responsibility but for its challenge to the constructive forces of democracy. On our response to that challenge now the future of local government and even of democratic government in Britain may well depend. The problem of relating knowledge and action in ways which satisfy both the technical need for planning over wider areas and the democratic need for execution of the plans by far smaller communities in which the personal touch, local knowledge and patriotism can play their vitalizing part, is an old one. Goodwill and active support of every scientific worker will be required, individually, through his professional associations, and perhaps not least in assisting the universities to recognize and discharge their regional responsibilities.

E. S. BEAVEN, A GREAT BARLEY EXPERT

Barley

Fifty Years of Observation and Experiment. By Dr. E. S. Beaven. Pp. xx + 394 + 27 plates. (London: Gerald Duckworth and Co., Ltd., 1947.) 30*s*. net.

IT is difficult to convey to this generation any adequate impression of the giant personalities that gave the Victorian era such brilliance and distinction. E. S. Beaven was one of them. Barley was his great life interest: he was the son of a barley grower, and son-in-law of a maltster whose business he entered as a youth; all his life was spent in handling barley and he knew it more intimately than any of his generation or this. But it was not only as a barley expert that he was known and respected: he was typical of his time, a sturdy, vigorous, forceful personality, outspoken, scathing in his denunciation of anything State-aided or other spoon-feeding agency; a stout believer in self-help, in some of his contemporaries, and in himself.

Beaven entered his father-in-law's business in 1878 when the malting barley most commonly grown was probably 'Chevalier', a variety accidentally discovered by a farm worker John Andrews at Debenham, Suffolk, and multiplied by his landlord, the Rev. J. B. Chevallier, after whom it was named—an 'l', however, being dropped during the process. This barley is of excellent malting quality, but it has some disadvantages: its straw is liable to be weak, and its neck, that is, the part between the uppermost node and the ear, is long and liable to bend over as the ear gathers weight; it becomes brittle during the desiccation accompanying maturation, and is liable to break so that the ears are lost.

There were, however, numerous other sorts in cultivation, including 'Archer', an old English variety of unknown origin, characterized by rather late ripening, a short neck, rather grey-coloured grain, better yielding capacity than 'Chevalier' but of lower malting quality; and 'Spratt', described in Lisle's "Essays on Husbandry" (1757), which, however, was grown only locally, chiefly in a few scattered districts in the Fens and in Essex: it had very stiff straw, could stand up where many other sorts would 'lodge', and was capable of high yields. In Beaven's youth another variety came into general use: 'Goldthorpe', raised from a single ear found by Mr. Dyson of Goldthorpe, Yorks, in 1889 in a field of 'Chevalier' barley. This was a considerable improvement on the existing sorts, and the fact of its discovery and its spread made a deep impression on him.

Beaven knew also of the Danish experiments on barley begun in 1882, and was much impressed by the valuable results yielded by the variety trials made there between 1893 and 1902. He began field experiments at Warminster in 1895, starting with single-plant cultures of various established races of barley and gradually expanding his programme. Then in 1902, in order to cope with the disconcerting depredations of birds, he erected a large bird-proof wire structure (later enlarged) under which special cultures could be grown. In all, his experimental ground finally covered about four acres.

Large numbers of single-line cultures were made, and those that came out best were further tested on a larger scale at Warminster and Cambridge; two soon came into general cultivation: 'Plumage' (of Danish origin) and 'English Archer'. He quickly realized the limitations of the selection method: while it furnished strains of higher yielding capacity, it could not introduce any new characters. So with the active help of R. H. Biffen and T. B. Wood (who became his son-in-law) he commenced hybridization in his cage, discarding unsuitable plants from the F generation onwards, but carrying on the most promising to the F_6 generation. The surviving sorts were then transferred to small plots, replicated but not randomized—this refinement had not yet been introduced and in any event Beaven did not approve of it; the final selections were then multiplied up and compared with the standard sorts in the field, the seed being sown in a drill divided into two halves, so that two sorts could be sown in alternate half strips. His first great triumph was the production of 'Plumage–Archer', which speedily became very popular among farmers; but others of his productions achieved considerable fame, and undoubtedly his labours contributed largely to the marked increase in yield of barley that has occurred since 1900. No one in Great Britain has done so much and so well for barley as he.

Beaven's success was due to his amazing gift for recognizing the qualities of barley. He knew by some intuitive process which of his many seedlings to reject and which to retain. He combined the artist's eye and the scientist's recognition of the need for full and accurate records, though he always disclaimed any scientific merit.

It was well known that he had accumulated large numbers of data, but during his active life he could never be persuaded to work them up: it was, indeed, feared that they might be lost. Fortunately he did in the end summarize his results; and although he has not lived to see the book, the devoted labours of Miss N. Stallwood have ensured its completion. To her is owed a great debt of gratitude, for it would have been a tragedy had the records remained unavailable to later workers.

Work of this sort is not likely to be done in the future, for the day of the non-professional scientific worker is past: no one now has the necessary means. Yet it must be admitted that some of the greatest advances in agriculture, as indeed in other subjects, have been made by non-professional workers combining the scientist's skill in ascertaining facts with the artist's perception of what lies behind them—often seeing further than the facts seem to warrant. It still remains to be seen how far the organised labours of teams of trained workers can go in achieving comparable results.

E. JOHN RUSSELL

ELEMENTARY PHYSIOLOGY

Introduction to Physiology

By Prof. W. H. Newton. Pp. 284. (London: Edward Arnold and Co., 1948.) 7*s*. 6*d*. net.

PHYSIOLOGY is a subject covering such a wide range of interests, and involving so many other branches of science, that teachers of it tend to have their own individual ways of approach. Most of them, after trying various ways of introduction to the subject, end up by considering, first, what that great teacher of physiology, Sir Michael Foster, called the 'master tissues' of the body, the muscles and the nerves. Prof. W. H. Newton, when he comes to deal with the different systems, also adopts this order; but his approach is refreshingly individual. He begins with an interesting chapter on "The Fire of Life" and passes on to a study of the control of temperature in the body, before he deals with the nerves, from the double aspect of the mechanism of nervous activity and organisation of the nervous system, and with the muscles, which he considers from a wide point of view under the heading 'movement'.

Throughout the book there are evidences of wide teaching experience in the shape of simple illustrations and analogies. In the main these are useful, though occasionally some of the drawings seem so simplified as to be unnecessary and the analogies to be unduly strained. The early chapters, interesting and unusual as they are in their presentation in a book of this kind, are likely to be hard reading for the ordinary lay person, though admirable for students of physiology whether working in the medical or science faculties.

As, however, nearly one-third of the book is devoted to these introductory chapters, the rest of the body has to be less fully considered; though here again valuable and less usual aspects of the systems are stressed. There are, for example, good sections on the factors controlling the circulation in different organs, on the functions of the kidney, short but excellent paragraphs on integration, and instructive maps showing the relationship between the amount of iodine in water supplies and the incidence of goitre as shown by the Army recruiting figures from the United States.

Altogether the book provides an interesting and thought-provoking introduction to a subject of much practical importance, and is one which should help those for whom knowledge of physiology forms a part of their training to a realization of its fascination.

W. C. Cullis

FUNDAMENTALS OF HEAT ENGINES

Elements of Applied Energy

By Prof. Frederick T. Morse. Pp. ix+444. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1947.) 30*s*. net.

THIS book, by the professor of mechanical engineering at the University of Virginia, may best be described as an up-to-date heat engines text-book of an essentially descriptive character. It is intended as an introduction to heat power for second-year students, to show them "the how and why of machines and other equipment in which energy plays a part". As such, it should fulfil its purpose admirably, the subject-matter being presented and illustrated in a manner which makes its reading particularly easy and agreeable.

It makes no claim to deal with the underlying theory, the mathematics being limited to occasional formulæ inserted in the text, and presented without proof. The limitations imposed by this method of presentation inevitably lead to occasional difficulties, which on the whole are successfully overcome; but it is disappointing to find such inaccuracies and over-simplifications as "hence isentropic process is a synonymous expression" (for adiabatic process); or "in the reaction turbine the nozzles are themselves attached to the shaft", even though these statements be qualified later in the text.

The extent to which this book brings its subject up to date may be judged by the fact that sections are included on atomic energy, gas turbines, jet engines and the war-time rockets and flying bombs. These sections form a small proportion of the 435 pages, the greater part being devoted to a modern presentation of the subjects commonly met with in a heat engines text-book such as this. Useful tables of the properties of steam and other fluids are included in a supplement.

In general, the book might best be described as suitable for higher national certificate courses in Britain, though this does not mean that the book is unsuitable for courses leading to an honours degree; its agreeable manner of presentation makes it very suitable for spare-time reading by the honours student, to provide him with the necessary practical background to his more theoretical studies, and in that way to stimulate his interest.

R. W. Haywood

ELEMENTARY THEORY OF ELECTRICITY AND MAGNETISM

Electricity, Magnetism and Modern Physics

A Textbook for the use of Scholarship Candidates and University Students. By Dr. G. T. P. Tarrant. (Being Vol. 2 of Physics.) (Dent's Modern Science Series.) Pp. xii+468. (London: J. M. Dent and Sons, Ltd., 1948.) 15*s*.

THE author states in his preface that this book is intended for students of physics who have placed the higher school certificate examination behind them and are proceeding to university scholarships or degrees, and there is no doubt that he has succeeded in producing one ideally suited for them. Much care and thought have obviously been given to the elucidation of the more difficult points in the theory of electricity and magnetism which are so often passed over in silence. The opening synopses of the histories of electricity and magnetism are likely to be very helpful to those students who might otherwise be worried by our modern conventions and order of presentation of the subjects.

The author is particularly sound in his discussion of dimensions, although the reviewer prefers to take e as a fundamental quantity in these modern days. The mathematical portions of the book are set out fully and in a manner which the average student should find easy to follow, and there are tables of practical importance, such as that of magnetic quantities on p. 278, which are very valuable in a book of this kind.

About three-fifths of the book are devoted to what is usually termed modern physics, and of which there is a survey fully adequate for the pass or general degree student. There are one or two small blemishes in the chapter on the theory of magnetism; for example, it is desirable always to emphasize that it is the magnetization vector of a domain which rotates, and this is best done by inserting the word vector wherever possible. Again, the figure on p. 284 and the use of italics on p. 286 may give the impression that Bitter figures are formed only upon a surface to which an applied magnetic field is perpendicular. Most teachers will appreciate the clear and helpful diagram which illustrates Dunnington's (not Duddington) method for finding e/m; but the inclusion of an electron path in the Bainbridge mass spectrograph may put dangerous ideas into students' heads. But these suggestions should not be taken to detract from a book which is warmly welcomed.

L. F. Bates

Our Inner Conflicts

A Constructive Theory of Neurosis. By Dr. Karen Horney. Pp. 250. (London: Kegan Paul and Co., Ltd., 1946.) 10*s*. 6*d*. net.

MANY attempts have been made to modify the original Freudian technique and theories regarding the origin and treatment of neurosis. This book describes the variations which Dr. Horney has developed and gives an outline of her views on psychology, which are interesting and coherent. The first thing which strikes the reader is that the analyses she records are not transference analyses in the Freudian sense at all and, in fact, the word 'transference' does not appear in the index. She does not believe, with Freud, that neuroses are caused by some distortion of the instinct but that they are the product of abnormal personality. She thinks that anxiety is produced by isolation, for example, and not by castration fears or birth trauma; that obsessions are due to disturbed personal relationships and not to repressed sadistic impulses, and so on. Her views on personality are individual also. She believes that there are three types: (1) compliant, (2) aggressive, (3) detached. They are really devices to deal with the patient's basic anxiety. This anxiety is also avoided by idealization of the ego, so that the patient is able to see himself as more perfect than he really is. The neurotic conflicts, she thinks, often lead to diversion of energy from useful channels, so that there is an impoverishment and inertia, the final stages of which are an all-pervading feeling of hopelessness.

Dr. Horney's psychology is half-way between that of Freud and Adler. She has a moralistic approach and her analytical technique is purely interpretative, but her views are based on clinical work and will be of interest to the psychotherapist, particularly those with Adlerian inclinations. CLIFFORD ALLEN

Practical Physiological Chemistry

By Dr. Philip B. Hawk, Dr. Bernard L. Oser and Dr. William H. Summerson. Twelfth edition. Pp. xiv+1323. (London: J. and A. Churchill, Ltd., 1947.) 50*s*.

THE rapidity with which advances are made in our knowledge of biochemistry and the fields of study with which it shares common ground makes the frequent revision of text-books dealing with these subjects a real necessity. It is ten years since the publication of the eleventh edition of Hawk's "Practical Physiological Chemistry", so that the appearance of a new edition is both timely and welcome. In the forty years since its first publication, this text-book has achieved a position which is probably unique. It is of value to teachers, research workers and routine analysts alike, the treatment of most aspects of the subject being both theoretical and practical and the scope of the experimental sections the widest possible.

The extensive additions and revision which have now been made will undoubtedly greatly increase its value to all its users. The changes embodied in the new edition are too many to mention in detail; but the following are some of the more considerable ones. A new chapter has been added, dealing with antibiotics, including penicillin, gramicidin, tyrocidine and streptomycin, and with metabolic antagonists, including analogues of vitamins and amino-acids. The chapter on enzymes has a new section concerned with cellular respiration, in which the Warburg manometric technique is described. The section on colorimetry has been extended to include a detailed account of various types of photometric technique. Other recently developed experimental techniques which are now discussed are microbiological assay of vitamins and amino-acids, polarography, use of isotopes and electrophoresis.

The chapters on hormones and vitamins have been extended to cover the enormous developments which have taken place since 1937, considerable attention being paid to the estimation of vitamins: it is in these sections more than in any others that the extent of the progress made in the last decade is apparent. Several new appendixes have been added, including one dealing with the analysis of variance, and a new feature is the inclusion in each chapter of a bibliography of relevant recent publications. These additions and many others have necessitated a considerable increase in the size of the book, which is, however, still very clearly printed and well indexed. In summary, it may be said that the new edition should ensure the maintenance by this book of its well-deserved popularity.

My Caves

By Norbert Casteret. Translated by R. L. G. Irving. Pp. xi+172+16 plates. (London: J. M. Dent and Sons, Ltd., 1947.) 15*s*. net.

THIS is a book which the general reader will enjoy and find exciting as well as informative. M. Casteret, well known already for his earlier study, "Ten Years under the Earth", has written it "not . . . as a technician, but as a dilettante", and in taking the reader "on a pleasure outing in the cave-country" he writes vividly of his experiences in pot-holing, in "reptation" and in the patient observation of the habits of bats. He devotes a chapter to each of these activities, and deals also with the purpose of spelæology and the equipment needed for its pursuit. He displays, as well as considerable courage, a sense of humour and an æsthetic, indeed almost mystical, appreciation of the wonders of the underworld. He writes with respect of the pioneers of cave exploration and marvels at the Palæolithic troglodytes. Enough is said of the value of spelæology to the geophysicist, the botanist and the hydro-electric engineer to show that it is more than a sport, though the appetite for scientific knowledge is no more than whetted.

The photographs, some taken underground by M. Casteret himself, are interesting and varied, and the translation is good and reads quite naturally, although English equivalents for some French technical terms had to be devised.

An Introduction to Filmstrips

By H. R. and I. W. Dance. Pp. 36. (London: George G. Harrap and Co., Ltd., 1948.) 2*s*. 6*d*. net.

THIS pamphlet contains a deal of common sense in a short space. Written with the needs of the classroom teacher firmly in mind, the technical processes of filmstrip production, the pros and cons of different types of apparatus and the basic principles involved in the use of this form of teaching aid are dealt with succinctly, lucidly and objectively. The line drawings and half-tone illustrations which accompany the text where necessary are admirably chosen for their purpose. On the most controversial point dealt with, the choice of frame size, the authors present a strongly argued case in favour of double-frame strip (24 mm. × 36 mm.) for general purposes, while agreeing that in certain instances single-frame strip (18 mm. × 24 mm.) will continue to be used.

There is still a tendency in many quarters to regard cinematograph film as almost the only form of visual aid worth mentioning. Ciné-film will always play an important part in education, but for regular classroom use the more humble filmstrip has much to commend it. The apparatus required is compact, weighs little and is easy to operate. The medium can be adapted to most classroom needs, is economical of time and allows considerable control of material by the user. Further, at very moderate cost the teacher can try out his own ideas in the way of filmstrip production—and will learn much in the process. Users of filmstrip, whether or not they are interested in amateur production, will find the practical suggestions in this little book helpful and stimulating without being dogmatic. ERIC LOWE

The Artificial Insemination of Farm Animals

By John W. Bartlett, George E. Taylor, Joseph Edwards, Clair E. Terrill, Victor Berliner and Fred P. Jeffrey. Enos J. Perry, Editor. Pp. v+265. (London: Chapman and Hall, Ltd., 1947.) 15*s*. net.

THIS book originally appeared in the United States in 1945. Since then much practical experience has been gained in the application of artificial insemination, both in the United States, where some million and a half cows are by now being registered annually for insemination, and in Britain, where a network of insemination centres will soon cover the country. Research work stimulated by this rapid advance has also made considerable progress, and improvements in method are continually being adopted. Quite new problems are arising. Although in consequence of this rapid advance this English edition is in many respects already out of date, it is still the most comprehensive work on the subject in the English language, and will prove very useful as a general introduction for the student of agriculture and veterinary science and for the farmer who takes an interest in the advance of scientific method. To the specialist it will be rather less useful. The treatment is on broad general lines, and exact quantitative data are not usually given to support the arguments. The chapters which describe the technical aspects are the most important. The ones which deal with the genetical aspects of livestock improvement are of less value. ARTHUR WALTON

Forest Valuation

With Special Emphasis on Basic Economic Principles. By Prof. Herman H. Chapman and Prof. Walter H. Meyer. (American Forestry Series.) Pp. xii+521. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 36*s*.

THIS book represents the development of earlier work on valuation and finance by Prof. Chapman of Yale. The wide scope of the applied part can be inferred from the main contents: the evaluation of real property producing annual income; present worth of forests producing periodic income; costs of production versus profits and the role of compound interest; rates earned and the profit margin; rotations; taxation; damages; fire insurance; methods of appraisal of stumpage value; determination and application of conversion returns; and the appraisal of forestry purchases for future operations. Appropriate formulæ, mainly concerned with compound interest and discount, are provided for the many and various problems which arise in forest finance. The importance of discount as applied to future net income in determining the present worth of an enterprise is stressed. Market values have limitations, and confusion in the past has been caused by the limitations in the use of compound interest. The authors hope that their treatment marks the final departure from the original European sources of forest evaluation and statics as set forth in Schlich's "Manual of Forestry". Many of the problems illustrated in the book are therefore specifically North American, although the principles outlined have wide applicability.

Teachers of applied economics will be interested to note the emphasis on the great advantage to students of a grounding in economic theory. The first six chapters have this need in mind, and the hope is that by stressing these principles in their direct relation to forest economics and valuation, the subject has been vitalized and its importance made clear to professional foresters and to owners and operators of forest property. J. J. MACGREGOR

Le forze creatrici dell'uovo

Questioni moderne d'embriologia. Per Prof. Pasquale Pasquini. (Sapienza, Vol. 3.) Pp. 334. (Pisa and Rome: Libreria Vallerini, 1948.) 700 lire.

PROF. P. PASQUINI has provided Italian readers with a clear and well-illustrated introduction to modern experimental embryology. He opens with a historical chapter, in which the seventeenth-century controversy between epigenesis and preformation gives him an opportunity to define the fundamental problems. The next chapter, on the maturation of the gametes, gives a good, if elementary, account of the cytoplasmic organisation of the ovum; but, as so often in embryological works, is old-fashioned in its treatment of meiosis. After these preliminaries, we come on to experimental embryology proper. Although there is nothing very original in the author's treatment, he covers the ground adequately, bringing his book right up to date by accounts of such new developments as Holtfreter's studies on the mechanism of gastrulation and the various theories of organiser action. The Italians are fortunate in having such a text-book for university students in their early years; there is nothing similar available in Great Britain. C. H. W.

Bird Recognition

1: Sea-Birds and Waders. By James Fisher. (Pelican Books, A.175.) Pp. 190. (Harmondsworth and New York: Penguin Books, Ltd., 1947.) 2*s*. 6*d*.

ALL too often the elaborate descriptions of birds that give each detail of plumage with minute exactitude are not much help to recognition in the field. Mr. James Fisher, in a 'Pelican' devoted to sea-birds and waders, and entitled "Bird Recognition", writes not with one eye but with both eyes on the field worker, and the novice at that. All persons interested in ornithology will find this little volume helpful but no one more so than the beginner, who will find it a valuable aid to the identification of the many species of waders and gulls to be found on and near the sea. The illustrations consist of monochrome portrait sketches by "Fish-hawk", maps chiefly by Mr. W. B. Alexander, and diagrams, consisting of circular calendars, showing the distribution of the species throughout the twelve months. Much information is thus packed into a small space and a useful, helpful book results.

FRANCES PITT

THE GAS INDUSTRY IN BRITAIN*

By Dr. E. V. EVANS, O.B.E.,
South Metropolitan Gas Company

COAL is the foundation of Great Britain's power of survival, and the gas industry is one of the instruments which the people of this country have created to use coal to the best advantage. In other lands oil and water power may take the place of coal, but Britain has neither oil nor any substantial quantity of potential water power. The liberation of energy by the fission of certain kinds of atomic nuclei has led to a great deal of speculation, but in the present state of knowledge we have no warrant to assume that this achievement represents unlimited supplies of exceedingly cheap power. Coal is likely to remain the staple fuel of Britain for very many years to come, and it is a matter of gratification to observe that during the last decade the nation has come to realize the importance of conserving its coal resources.

It is now generally realized that, if used wisely, every ton of coal can do much more work in industry and provide higher standards of comfort and cleanliness in the home.

The British gas industry treats annually about twenty-two million tons of coal and employs directly some 130,000 persons for the purpose of rendering a public service. It provides fuel in the form of gas, of coke and, to a relatively small extent, as oil fuel. With the other great fuel and power industries of coal, electricity and oil, it strives in healthy competition to serve industry and the public as effectively as possible, and it would be unfortunate if, as a result of the nationalization of the fuel industries, the healthy competition which has in the past been an incentive to progress ceased to exist. On the other hand, it would show great wisdom and prudence if the administrators of the future were to allot to each fuel industry those services which in the national interests it should best perform.

The basic processes which are operated to convert coal into gas fall into the two groups of carbonization and gasification.

Carbonization consists essentially in roasting the coal with the exclusion of air, the heat causing the coal substances to decompose with the evolution of gas and tar. Coal consists mainly of compounds of the elements carbon, hydrogen and oxygen, in such forms that the greater part of the carbon in the original coal remains behind in the carbonizing vessel as coke. This coke is carefully prepared for use in industry and in the home, or it may be used in the gas works for the production of gas by processes of gasification, employing the reactions which take place between incandescent coke and air or steam to manufacture either producer gas or water gas.

A modern works carbonizing coal for the production of gas operates with high thermal efficiency, recovering as much as 85 per cent of the heat potentially available in the coal in the form of gas, coke and other products.

Forty years ago, gas making was an art, full of tricks and intricacies learned by constant practice and enriched by ingenuity; but the gas engineer of that time understood little of the nature of the processes he was conducting. To-day the chemist and physicist have placed these processes upon a scientific basis. In those earlier days what we now know as consumer service was a relatively simple matter. The responsibilities of the gas engineer and manager of to-day are quite different. In order that the processes of a gas undertaking may be operated efficiently and the service to the public equally efficient and reliable, the industry has built up a complex organisation with specialist sections.

The gas-holder, so familiar that it is a symbol of the gas industry, is an appliance of the utmost importance. Without gas-holders the productive capacity of the gas-making plant of Britain would have to be about five times as large as it is at present to permit the peak demands to be met. During the midday cooking period on a Sunday, the demand may be five times the average over the whole day, while at midnight the demand may fall to about one quarter of the average. The gas-holder permits these wide changes in requirements to be met, while the manufacturing process continues to operate at a uniformly steady rate throughout the twenty-four hours.

Over the last sixty years the output of gas has grown steadily year by year at an almost constant rate, although at the present time the rate of growth is about twice the average rate over that period.

There are in Great Britain about twelve million families, and as nine out of every ten already use gas it follows that the industry cannot look forward to any large increase in the number of customers. This, however, does not mean that it cannot look forward to any further increase in sales and, indeed, the present abnormally high rate of increase is taking place with almost no change in the total number of users. What is happening is that gas is being used for more and more purposes.

Although the original purpose of public gas supply was to provide artificial illumination, gas lighting represents to-day only about five per cent of the total gas sales. About one half of all the gas sold is consumed by domestic users for cooking, and these same families use a further fifteen per cent of the total for other domestic services, such as water heating, the heating of rooms, the washing and drying of clothes, and refrigeration for food storage. The quantity of heat required for these other purposes, if they are to be performed adequately, is much larger than that required for cooking, and in this fact lies the great scope for the further use of gas in the home. Commercial consumers take about twelve per cent of the total sales, and some eighteen to twenty per cent goes to industry.

The industry has in recent years given attention to the formulation of tariffs which, as nearly as may be, relate the price charged to the actual cost of supply, and it is interesting to record that domestic consumers of one large undertaking who have adopted a two-part tariff system of charge have practically doubled the quantity of gas previously used by them.

The basis of the industry's service is a scientific understanding of the principles involved. This applies not only to the manufacture and utilization of gas but also to the manufacture, preparation and utilization of such by-products as coke and tar.

Coke is to-day a carefully prepared smokeless solid fuel for which a variety of highly efficient appliances have been designed, many of them with gas ignition. For the long-period heating of rooms and for the provision of hot water in the winter months, coke is playing an important part in the efficient use of coal and the abolition of smoke.

The largest use of tar is as a waterproof binder for holding together the stone aggregate of road surfaces, and here a study of physical properties and methods of application has enabled the science of road construction to keep pace with the increasing severity of the demands made by traffic.

---

* Substance of a Discourse to the Royal Institution delivered on April 16.

The application of science to a practical problem may be illustrated by reference to the provision of comfortable warmth in the living-room of a dwelling house. The gas fire of the past was noisy, the fireclay elements were fragile and the sensation of heat was more often one of scorching than of comfort. The continuous noise of the fire when in use arose from the aerated flame burner in which the gas and air were mixed together before they reached the point of ignition. Much was done by studying the aerodynamics of the system to reduce the noise; but complete silence in operation was not achieved until the adoption of the non-aerated burner. These burners were not in themselves novel; but, so long as gas was sold for the intrinsic luminosity of its flame, the non-aerated type of burner could not be relied upon for heating purposes because of its liability to deposit soot. To-day, when gas is sold on its heating value and mainly for heating purposes, the rich hydrocarbons—benzene and its homologues—are recovered as motor benzole. This makes an important contribution to our supplies of motor spirit and at the same time produces a gas which can be burned in a non-aerated burner without risk of sooting.

The purpose of the fireclay element in a gas fire is to receive heat from the flame, being thereby raised to incandescence and emitting this heat by radiation. It was the practice to suspend the fireclay elements in the flame itself and if they were quickly to reach incandescence they had to be light, of small cross-section, and in consequence necessarily fragile. The difficulty was overcome by developing the observation that if gas flames are confined in a fireclay box and one wall of this box is perforated or slotted to a limited extent, the internal surfaces become incandescent and shine out through the slots or perforations. As the purpose of the perforated wall is to restrain the heat from escaping too rapidly, it can be made of robust material and the problem of fragility is overcome. The perforated fret has the further advantage that the apertures can be so arranged as to alter the geometrical distribution of the radiant heat, a matter of importance in the production of comfortable heating.

The study of heat comfort has revealed the necessity of providing such a degree of background heating that the temperature of the air, walls and furniture does not fall below 55° F., and ensuring that the radiant heat employed to supplement the background heating is emitted in a broad beam shining upwards and outwards. With these requirements satisfied a gas fire produces comfortable conditions within a few minutes of lighting and, what is more, the occupants of the room may sit in comfort around the fire for any length of time. The recognition of these requirements has led to the development of the convector gas fire which, in addition to providing the radiant heat, also recovers from the flue gases heat which is employed to warm the air of the room.

The application of scientific principles, of which the foregoing example is but one, has brought us to-day to the knowledge that greatly improved standards of comfort and hygiene may be provided with less consumption of fuel. The unsatisfactory standards of the past have involved the use of five to six tons of coal by a household each year. By employing gas and coke for cooking, water heating and space heating, and electricity for lighting and power, coal is saved and living conditions improved.

The gas industry has great potentialities for further development and goes forward into the future with pride in its past traditions, skill in its present technique, and confidence in its ability to play a large part in restoring the fortunes of Great Britain.

CHROMATOGRAPHICAL STUDY OF MERISTEMATIC PLANT TISSUES

By Dr. A. ALLSOPP

Department of Cryptogamic Botany, University of Manchester

Recent years have seen a revival of interest in the apical meristems of plants, but little has been done on the metabolism of these regions. The lack of suitable methods for dealing with small amounts of tissue may be held accountable for this state of affairs; but the development of paper partition chromatography seems likely to provide a method of first-class importance in metabolic studies of apical meristems, or indeed of any other tissues which are available only in restricted quantity.

Paper chromatography was first described in detail in 1944 by Consden, Gordon and Martin[1] as a method for the qualitative analysis of proteins. The same workers[2] have recently adapted it to the identification of lower peptides, while others have developed the technique for the qualitative[3,4] and quantitative[5,6] analysis of sugars. The quantitative analysis of amino-acids has also been reported in outline[7,8]. Lugg and Overell[9] have described a quantitative method for organic acids, while Crammer[10] has used paper chromatography in the separation of flavine nucleotides. Further developments may be anticipated; but the existing methods already provide valuable equipment for the investigation of plant materials.

The only work yet published which deals with a systematic examination of a plant tissue by paper chromatography is that of Dent, Stepka and Steward[11], who investigated extracts of the soluble nitrogen of disks of potato tissue. In the work outlined in the present communication, examination was made of the amino-acids contained in cold 70 per cent alcohol extracts and in acid hydrolysates of the residues of various plant tissues. The solvents used in the chromatography and other details of technique were similar to those described by Dent, Stepka and Steward[11].

The initial object of this investigation was the study of the amino-acids, free and combined, of apical growing points; but as the work progressed it was considered desirable to provide a basis of comparison by examining a range of materials from some of the principal taxonomic groups of plants. The following materials were examined: thallus of *Gigartina stellata* (Rhodophyceæ); old thallus and young branches of *Conocephalum conicum* (Hepaticæ); shoot of *Polytrichum commune* (Musci); developing synangia and mature stem of *Psilotum triquetrum* (Psilophytinæ); leaf of *Isoetes echinospora* and stem of *Lycopodium Selago* (Lycopodinæ); apices of aerial shoots, nodal tissue and young induced lateral branches of *Equisetum giganteum* and prothalli of

Equisetum arvense (Equisetinæ); shoot and root apices and central tissue of root-stock of *Dryopteris aristata*, prothallus of *Osmunda regalis*, and prothallus and leaf of *Angiopteris evecta* (Filicinæ); buds of *Ginkgo biloba* and young branches of *Ephedra altissima* (Gymnospermæ); and flower buds and mature stem of *Cheiranthus Cheiri* (Angiospermæ).

Analyses of root tips of *Dryopteris* were based on the terminal 3 mm. from seventy-six roots giving a total fresh weight of 0·057 gm. The meristematic tissue of the shoot was obtained from three well-grown stocks. After removal of scales and leaf primordia a cylinder of tissue carrying the apical cone was obtained by driving a cork borer vertically through the stock. A razor was then used to cut off a thin disk of meristematic tissue bearing the apical meristem and minute leaf primordia only. The combined fresh weight of the three disks was 0·032 gm. Growing-points of *Equisetum giganteum* were exposed by removing the sheathing leaves, and the terminal 2 mm. from a number of shoots were combined to give a total fresh weight of 0·05 gm. The single prothallus of *Angiopteris* was 0·151 gm. and a portion of a large prothallus of *Osmunda* of fresh weight 0·172 gm. was used. Similar amounts were used of the other tissues examined.

The tissues were weighed into small stoppered ignition tubes and crushed with sufficient 90 per cent alcohol to give a final concentration of 70 per cent. The extracts were removed by centrifuging, and extraction was repeated with 70 per cent alcohol (five to six times in all). Several volumes of 6 *N* hydrochloric acid were mixed with the residues and, after sealing, the tubes were placed in an oven at 100° C. for 20–24 hr. After cutting open the tubes, while wearing goggles, the insoluble residue was removed by centrifuging. Extracts and hydrolysates were evaporated to dryness under reduced pressure without heating. The product was redissolved in a small quantity of water (0·10 c.c. or less) and aliquots taken for chromatography. Usually one-tenth of the sample was used for one-dimensional chromatography, with phenol as solvent, as an indicator of the amount required for two-dimensional chromatography. Two-fifths of the extract was usually suitable for the latter.

In these small amounts of apical tissue, the protein content was sufficiently high to yield good chromatograms from the acid hydrolysates. Thus the following amino-acids were identified in hydrolysates of the shoot apex of *Dryopteris*: aspartic acid, glutamic acid, glycine, serine, threonine, alanine, arginine, lysine, proline, valine, methionine, leucine, phenyl alanine and tyrosine. Tryptophane is destroyed under the conditions of hydrolysis, while cystine and histidine do not yield well-marked spots under the conditions and concentrations utilized. Hydrolysates of the root apices and of tissue from the middle of the root-stock yielded chromatograms showing the same amino-acids, with no evident difference in their proportions, although the total amount was several times greater in the stem apex than in an equal fresh weight of the central tissue of the stock. The same amino-acids were obtained from *Equisetum* shoot apices and from nodal tissue of the same plant.

The free amino-acids, extracted from the apices by 70 per cent alcohol in both *Dryopteris* and *Equisetum*, formed only a small fraction of those liberated from the tissues by acid hydrolysis. In the *Equisetum* apex only glutamic acid and aspartic acid were found. In root and shoot apices of *Dryopteris*, glutamic acid was most prominent with aspartic acid also present in appreciable quantities. Glutamine was present in the root tips, but was not detected in the shoot apices, although tissues immediately behind the apex contained moderate amounts. Faint tyrosine spots were obtained from both root and shoot apices but were more prominent in the former. In both cases the chromatograms showed a well-marked spot in the leucine position. Methionine and *iso*leucine occupy the same position with the solvents used for the two-dimensional chromatography, but a one-dimensional chromatogram using 1 : 1 butanol-benzyl alcohol as solvent indicated that this spot was from leucine only. Tissue from the centre of the stock of *Dryopteris* was also relatively low in free amino-acid content, but in this case more acids were present and included aspartic acid, glutamic acid, glutamine, arginine, valine and leucine. It remains to be seen to what extent the free amino-acids are influenced by season and by varying experimental conditions.

Examination of the plant materials listed above has revealed marked differences in the free amino-acid content, and a truly striking correspondence between the chromatograms produced from the acid hydrolysates. Clear chromatograms were obtained from all the plant materials listed with the exception of *Equisetum* prothalli and *Lycopodium* stems, in both of which the protein content of the amount of tissue taken was insufficient for two-dimensional chromatography. In *Lycopodium*, however, it was possible to identify aspartic acid, glutamic acid, serine, valine and leucine. In chromatograms of all the other species the amino-acids already listed for *Dryopteris* were present in every case, with the possible exception of the leucines. In *Isoetes* leaf and *Psilotum* synangia only *iso*leucine was detected; but no hydrolysate remained to test whether this was also characteristic for the shoot tissue of *Psilotum*. Only leucine was detected in all parts of *Dryopteris*, in *Conocephalum* and in the prothallus of *Angiopteris*. Both *iso*leucine and leucine were present in the other materials tested, which included all those listed with the exception of *Angiopteris* leaf, *Equisetum* prothallus and *Lycopodium* and *Cheiranthus* stems. Apart from these differences in the leucines the chromatograms were virtually alike. In addition to the amino-acids named above, the stronger chromatograms showed a characteristically purple spot lying in advance of valine and the leucines in the direction of movement of the phenol and between them in the collidine direction. This spot occupies a position different from any amino-acid the R_F values of which have been published, and may prove to be new. It has been found in chromatograms from *Polytrichum*, *Psilotum*, *Isoetes*, *Equisetum*, *Ginkgo*, *Ephedra* and *Cheiranthus*. It is possible that more concentrated hydrolysates would have shown its presence in the other tissues investigated. All the amino-acids named here have recently been reported for hydrolysates of the bacterium *B. coli*[12]. This remarkable correspondence of amino-acids in so widely separated groups of plants raises the question whether the significance is one of phylogeny or of essential metabolic requirements, but our present knowledge of the functions of the amino-acids is insufficient to warrant an answer.

In contrast to the amino-acid pattern of the hydrolysates, wide differences were found in those of the alcohol extracts. The free amino-acid content was notably low in mature tissues not specially adapted for storage. This was the case in leaves of *Isoetes* and *Angiopteris*, in thalli of *Gigartina* and *Conocephalum* and in stems of *Lycopodium*, *Equisetum* and *Psilotum*. Resting buds of *Ginkgo* and prothalli of *Equisetum* were also low in amino-acid content. No amino-acids could be detected in the leaf of *Angiopteris* and stem of *Lycopodium*, but in the other materials glutamic acid was always prominent in spite of the low total amino-acid content. Aspartic acid was also present in every case. The rather bulky prothalli of *Angiopteris* and *Osmunda* contained appreciable quantities of a few individual amino-acids. *Angiopteris* contained only aspartic and glutamic acids and a larger quantity of a substance, possibly a peptide, giving a purple reaction with ninhydrin but not occupying the position of any known amino-acid on the chromatogram. The *Osmunda* prothallus contained aspartic and glutamic acids, glutamine, a larger quantity of serine and a still greater amount of a substance occupying the same position as that of the unknown of *Angiopteris*. Slowly developing synangia of *Psilotum* and shoots of *Polytrichum* occupied a middle place in amino-acid content. In both materials, aspartic acid, glutamic acid, asparagine, glutamine and smaller amounts of other substances not further characterized were present. The only materials yielding a high proportion of free amino-acids were the developing flower buds of *Cheiranthus*, actively growing branches of *Ephedra* and induced branches of *Equisetum* and *Conocephalum*. In the two cases investigated in detail, namely, *Ephedra* and *Cheiranthus*, the chromatograms corresponded in individual amino-acids to the hydrolysates, but contained, in addition, asparagine and glutamine and several substances not yet identified.

The connexion emerging from this survey between content of free amino-acids (and peptides) and growth activity of the tissues appears too close to be lacking in significance. The abundance of free amino-acids found in actively developing tissue is apparently in contrast with the observations of Dent, Stepka and Steward[11], who record that under conditions of protein synthesis in potato disks, certain of the amino-acids decrease in amount to such an extent that they are no longer visible on the chromatograms. In their work, however, the synthesizing tissues were isolated from other sources of amino-acids, whereas in the present instance the growing tissues could draw on nitrogenous substances from the rest of the plant. The connexion between active growth and abundant supplies of free amino-acids is supported by the observations on induced branches of *Equisetum giganteum* and *Conocephalum*. In *Equisetum* removal of the shoot apices led to the rapid growth of lateral branches from the nodes. In *Conocephalum* rapidly growing branches developed from the edges of an old thallus placed in a warm damp atmosphere. In both materials the actively growing branches contained an abundance of free amino-acids which were comparatively deficient in the adjoining mature tissues.

The several points of interest emerging from this survey may now be summarized. In the first place, these preliminary observations indicate that the combined amino-acids of the apical meristems are not appreciably different in nature or proportion from those in mature tissues. A striking correspondence is also noticed between the amino-acids of acid hydrolysates of representatives from widely separated groups of plants. A connexion is found between the amounts of free amino-acids and the activity of development of tissue, and among the free amino-acids the ubiquity of glutamic and aspartic acids is very striking. It is a reasonable anticipation that many additional points of interest will emerge from use of quantitative methods in conjunction with paper chromatography.

In conclusion, I wish to thank Prof. C. W. Wardlaw for his encouragement and helpful criticism and Dr. C. E. Dent for his valuable advice on the technique of paper chromatography.

PAPER CHROMATOGRAPHY OF ANTHOCYANINS AND RELATED SUBSTANCES IN PETAL EXTRACTS

By E. C. BATE-SMITH

Low Temperature Research Station, Cambridge

THE work of Lawrence and Scott-Moncrieff[1] indicates that in *Dahlia variabilis* five genetic factors control the development of petal colour. The factor *A* determines 'light' anthocyanin pigmentation, *B* 'heavy' anthocyanin, *Y* yellow anthoxanthin and *I* ivory anthoxanthin. A factor *H* inhibits the action of *Y*. In absence of *Y*, anthocyanin is mainly cyanin; but in presence of *Y* pelargonin preponderates. *Y*, when uninhibited by *H*, completely suppresses ivory anthoxanthin production by this factor *I*. The presence of *I* is indicated in cyanic types by a blueing effect on the petal colour.

The methods used by Lawrence and Scott-Moncrieff to identify these pigments were based on tests described by Robinson and Robinson[2]. An extract of the crushed petals in 1 per cent hydrochloric acid contains all the pigments, and from it the anthoxanthins can be extracted by repeatedly shaking with ethyl acetate. The anthocyanins react with sodium carbonate, giving a tint varying from blue to red-violet as the cyanic constitution varies from pure cyanin to pure pelargonin. Yellow anthoxanthin was detected by shaking the ethyl acetate extract with saturated sodium carbonate, giving an intense golden brown coloration[1]. Ivory anthoxanthin was detected by its giving a yellow or green reaction in these circumstances in absence of yellow anthoxanthin. In presence of the latter it was detected by the blueing effect of an acid anthoxanthin extract on a standard cyanin solution.

All four pigments, when present, can be readily demonstrated in a 1 per cent hydrochloric acid extract of petals by the paper chromatographic method of Consden, Gordon and Martin[3]. Phenol, collidine, and butanol–acetic acid–water (40 : 10 : 50 by volume) have been tried as solvents; the last-mentioned gives the best results, and has been used in all the present work. In this way the pigment

R_F VALUES IN BUTANOL–ACETIC ACID–WATER (40 : 10 : 50) AND COLOUR OF ANTHOCYANIDINS AND THEIR MONO- AND DIGLUCOSIDES

The values in brackets in the first row of data refer to fainter spots accompanying the main spot. These were seen only in chromatograms of anthocyanin chlorides dissolved in water without further addition of hydrochloric acid. They are likely to represent tautomeric forms of the anthocyanin colour base. In hydrochloric acid only one spot corresponding to one anthocyanin type has been observed, and this forms an additional reason for preferring a hydrochloric acid to an aqueous extract.

constitution of a large number of seedlings can be demonstrated in a few hours, giving a permanent record which can be filed for reference purposes.

The results to be described were obtained mainly with *Dahlia variabilis* during the latter part of the 1947 season. Some at least of the R_F values quoted must be regarded as provisional. The values for cyanin, for example, vary to some extent from one run to another, and until the causes of this variation are understood and controlled the identity of an anthocyanin cannot be established by reference merely to its position on the chromatogram, nor with certainty even by comparison with a standard anthocyanin run side by side. Part of this variability has been traced to the effect of the hydrochloric acid with which the petals are extracted. In the case of cyanin, for example, the anthocyanin, changing colour at about *p*H 3, is present as the oxonium chloride in the original 1 per cent hydrochloric acid solution; but as it travels down the paper it is equilibrated with the acetic acid solution at a higher *p*H, and is partly converted into the colour base. The effect can actually be seen in a slight change in the colour of the spot from pink to mauve. The salt travels at a slower rate than the colour base, so that the R_F of an anthocyanin applied to the filter paper in hydrochloric acid solution is less than that applied in neutral solution.

In spite of this difficulty, the use of 1 per cent hydrochloric acid has a number of advantages. The spots formed are less diffused than those from aqueous extracts; and a uniform practice of running chromatograms from 1 per cent hydrochloric acid solutions smooths out any difficulties due to variation in sap *p*H and also makes it unnecessary to remove acid after carrying out mild hydrolysis.

The R_F values are, fortunately, not the only evidence upon which the identity of a pigment can be established. The spots formed by these substances have distinctive colours both in ordinary and ultra-violet light, and these colours also change in a distinctive way when the papers are treated with ammonia vapour. For example, cyanin forms a blue-mauve spot becoming blue-green in ammonia vapour, peonin a rose spot becoming blue. Apigenin forms an ivory spot scarcely visible in ordinary light but becoming lemon-yellow in ammonia vapour, and having a light-brownish fluorescence in ultra-violet light.

The ultra-violet source employed was an 'Osira' lamp having some emission in the visible region.

The identification of the sugars formed after hydrolysis of the glycosidic pigments by the application of Partridge's method[4] presents no difficulty provided sufficient material is available. It should be noted that certain polyphenols, for example, catechin, will reduce ammoniacal silver nitrate in the cold, and this will form an additional means of identification of such types.

Specimen Anthocyanins. A limited number of natural and synthetic anthocyanins have been available for comparison with the types found in petal extracts, namely: synthetic cyanin, peonin, malvin, and hirsutin chlorides; cyanin from cornflower (*Centaurea cyanus* Linn.) containing a second component thought to be cyanidin monoside; cyanidin monoside from blackberries (*Rubus fruticosus* Linn.) which proved to contain a second, unidentified component.

These have been chromatographed in aqueous and hydrochloric acid solution and also after subjection to progressive hydrolysis. The spots applied to the paper contained about 5 μgm. of the pigment chloride. The R_F values obtained in butanol–acetic acid are given in the accompanying table.

Anthocyanins of D. variabilis. All cyanic varieties examined to date have shown two spots with R_F values varying between 0·12 and 0·19, and 0·25 respectively. After removal of acetic acid from the paper the former is blue-mauve and corresponds exactly in behaviour with the natural and synthetic cyanin. The second is rose-pink, and can be taken, pending similar confirmation, to represent pelargonin.

D. Merckii, on the other hand, shows in the ray petals two blue-mauve spots, R_F 0·12 and 0·16, the first corresponding with cyanin and the second of uncertain identity, pelargonin being absent. The disk florets, shown by Lawrence and Scott-Moncrieff to contain cyanidin 3-monoside[1], also form two blue-mauve spots, one, unidentified, moving with R_F 0·06 and one corresponding with cyanidin monoside.

The presence of cyanidin monoside in deeply pigmented chocolate flowers of *D. variabilis*, reported by Lawrence and Scott-Moncrieff, is confirmed by the presence in the chromatograms of a mauve spot with R_F 0·31.

Anthocyanins of other species. Results with a number of other species which bring out points of particular interest may be mentioned.

Peristrophe speciosa (Necs.), reported to contain cyanidin diglycoside[5], shows no spot where cyanin would be expected, but shows a slow spot (R_F 0·04–0·06) of a bright rose colour. On hydrolysis with 5 per cent hydrochloric acid at 100° C. for five minutes, spots are formed which correspond with cyanidin monoside and cyanidin respectively.

Iris unguicularis Poir., reported to contain delphinidin diglycoside[5], gives two spots, $R_F \sim 0{\cdot}2$ and $0{\cdot}25$, both bluer in colour than cyanin and becoming green in ammonia.

Tibouchina semidecandra Cogn., reported to contain acylated malvin[5], has one very fast moving mauve spot, $R_F \sim 0{\cdot}63$, and a fainter one, $R_F \sim 0{\cdot}44$, becoming bright green with ammonia. On hydrolysis (as for *Peristrophe*) a spot corresponding with malvidin monoglucoside (R_F 0·31) appears.

Reviewing the data on anthocyanins as a whole, it can be seen that increase in hydrochloric acid concentration in the applied solution causes a fall, removal of a glucosidal sugar and methylation cause a rise, in R_F value. Certain regularities are apparent, but there are numerous anomalies in the way of consistent interpretation of the differences in R_F in terms of differences in constitution. Nevertheless, the position of a spot giving the colour reactions of a particular anthocyanidin type can already yield useful information as to its probable nature, especially if this knowledge is extended, as in the case of the *Peristrophe* and *Tibouchina* pigments, by chromatography of its hydrolysis products.

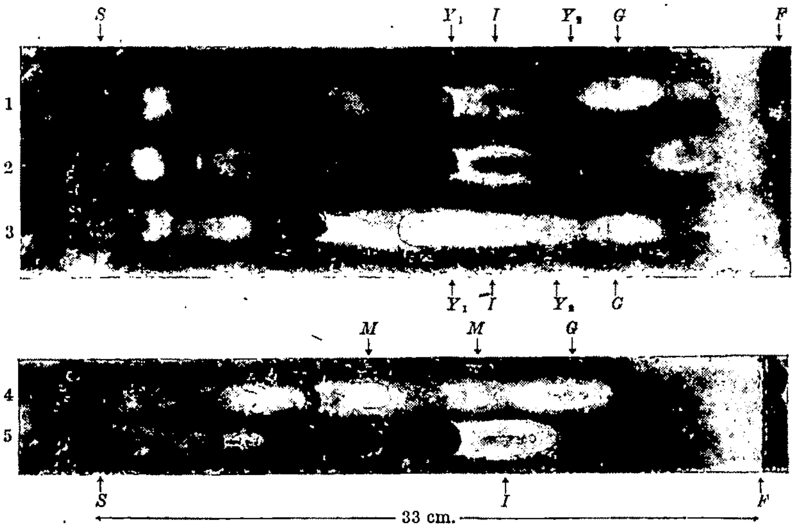
Yellow Anthoxanthin. In *Dahlia* this pigment has been identified by Price as the chalkone butein[6]. The pigment produces a long trail with all solvents tested, but there are concentrations into definite spots, the main one having R_F 0·55. After heating with 8 per cent hydrochloric acid for ten minutes at 100° C. the pigment becomes almost insoluble in water and its R_F increases to 0·85. This behaviour could be accounted for either by hydrolysis of a glycoside or by ring closure to the flavanone butin. That the former is more likely is indicated by the behaviour of a number of hydroxy chalkones (2- and 4-hydroxy, 2,3- and 2,4-dihydroxy and 2-hydroxy-4-methoxy chalkone), all of which had $R_F \sim 0{\cdot}9$. This would confirm Price's view that butein occurs as a glycoside in the dahlia petal. Owing to the trailing of this constituent it is advisable to remove it by extraction with ethyl acetate when studying anthocyanins.

Ivory anthoxanthin. Chromatograms of blue-red, rosy magenta and some white *Dahlia* petal extracts when treated with ammonia vapour show an evanescent lemon-yellow spot with $R_F \sim 0{\cdot}6$. Unless so treated this spot is not visible in ordinary light, but gives a characteristic light-brown or cream-coloured fluorescence in ultra-violet light (*cf.* accompanying illustration).

The ivory anthoxanthin in *Dahlia* was identified by Schmid and Waschkau[7] as apigenin and was thought to be non-glycosidic. This identification of the flavone has been confirmed by comparison with apiin, the 5-apioglucoside of apigenin. The following evidence suggests that the anthoxanthin is present in the petal as a glycoside.

Apiin gives a spot with the same characteristics as the *Dahlia* anthoxanthin spot, but with R_F 0·5. When subjected to mild hydrolysis in 1 per cent hydrochloric acid the R_F increases to 0·6. Hydrolysis in 10 per cent hydrochloric acid increases the R_F still further to 0·85, the fluorescent character of the spot remaining unchanged throughout. It is likely that these changes in R_F are due to the successive removal of apiose and glucose, and that the spots observed in the *Dahlia* extract chromatograms are due to a glycosidal derivative of apigenin, probably the 5-glucoside, rather than to the aglucone.

Other components of white petal extracts : substances giving colour reactions with ammonia. Lawrence and Scott-Moncrieff pointed out that white flowers free from apigenin may give a strong straw or maize colour when treated with ammonia vapour. The extract of one such flower, *DJ*/18 (an F_2 seedling from 'Murdoch' × 'Frau O. Bracht'), showed two spots, $R_F \sim 0{\cdot}4$ and 0·55, which gave permanent brownish stains when treated with ammonia. In ultra-violet light the untreated spots were barely visible ; but after treatment they fluoresced strongly (straw-coloured). It was suggested[1] that the substances responsible are tannins, and this possibility is being investigated by surveying the chromatographic behaviour of tannins and related substances.



CHROMATOGRAMS OF EXTRACTS OF PALE YELLOW AND WHITE FLOWERS. APPEARANCE IN ULTRA-VIOLET LIGHT

1. "Frau O. Bracht" (pale yellow). 2. "Ballego's Surprise" (white sport from 1). 3. "D.J.L." (pale yellow seedling from 1). 4. "*DJ*/18" (white seedling from 3). 5. "Snow Princess" (white)

Y_1, position of main butein spot, the only constituent of these flowers giving spots visible in ordinary light ; Y_2, light brown spot corresponding with a secondary concentration of butein colour ; *I*, apigenin (? glucoside) ; *M*, spots becoming brown in ammonia vapour ; *G*, spots showing bright green fluorescence ; *S*,*F*, start and finish of chromatograms. Note (*a*) absence of *G* as well as Y_1 and Y_2 from 2 : otherwise identity of 1 and 2 ; (*b*) similarity of closely related 1 and 3, markedly different from unrelated 5.

Osira lamp. Ilford Rapid Process Panchromatic plate. Ilford Micro 4 filter. (Photographs by Dr. R. Gane and Mr. D. P. Gatherum)

To sum up, this investigation has shown promise of the possibility of identifying the anthocyanins, flavones and related substances present in petal extracts, employing their colour in visible or ultra-violet light, with and without treatment with ammonia vapour, their reaction with ammoniacal silver nitrate and their R_F values as distinguishing characteristics.

Even without exact identification of all the substances responsible, the spots seen on the chromatogram provide a means of rapidly characterizing genetical material and of tracing relationships between genotypes (*cf.* accompanying illustration).

Its greatest potential value would, therefore, appear to lie in the field of chemical genetics opened up by the work of Lawrence and Scott-Moncrieff which inspired the present investigation.

The help afforded by Prof. A. R. Todd in supplying anthocyanin chlorides and chalkones and by Dr. R. Hill in supplying natural anthocyanins and flavones made this investigation possible. Mr. D. F. Elsden carried out the experimental work, and Dr. S. M. Partridge's advice in its interpretation is gratefully acknowledged.

OBITUARIES

Prof. A. S. Eve, C.B.E., F.R.S.

Arthur Stewart Eve, who died on March 24 at his home at Puttenham in Surrey, was one of Rutherford's collaborators in early days at McGill. Throughout his life he had a fervent admiration for Rutherford, and his authoritative biography of Rutherford was a work of love.

The main facts of Eve's life are simple. Born in 1862 at Silsoe in Bedfordshire, he was educated at Berkhamsted School, whence he passed with a scholarship in 1881 to Pembroke College, Cambridge. He was fifteenth Wrangler and took a first-class in Part 2 of the Natural Science Tripos. He then went as a master to Marlborough, where he stayed for sixteen years, during the last five of which he was bursar. In 1903 he went to McGill, first in the mathematics and later in the physics department, and in the next year a series of papers began dealing with ionization by β- and γ-rays, with the ionization in the atmosphere and, somewhat later, with the amounts of radioactive substances present in rocks and in sea water. In 1909 he succeeded Rutherford as Macdonald professor of physics. Work was interrupted by the First World War, when Eve was responsible for raising the third and fourth University Companies as reinforcements for the Princess Patricia's Canadian Light Infantry. He went overseas as second in command of the 148th Battalion with the rank of major, and afterwards became a colonel in the Canadian Expeditionary Force. Though admirably suited to the command of men, the need for men with scientific training to deal with the submarine menace led to his becoming director of research at the Admiralty Experimental Station at Harwich. For his work there he was awarded the C.B.E. in 1918; in 1917 he had become a fellow of the Royal Society.

After the War he returned to McGill as director of physics, became dean of the Graduate Faculty in 1930 and retired with the title emeritus in 1935. In 1929 he was president of the Royal Society of Canada.

After his retirement to England came his 'life' of Rutherford, and he then undertook the heavy and long-delayed task of writing the life of John Tyndall from the large mass of material collected and partly arranged by Mrs. Tyndall. Eve produced a first draft, but a stroke prevented him from completing the book, which was eventually published in collaboration with C. H. Creasey and under their joint names.

Eve's true greatness lay in his personality, and this was at no time better shown than in his last years when by cheerful pluck and determination he recovered to a large extent from the stroke which had at first deprived him of speech and movement. He regained the power of speech and to some extent that of walking; he even managed to make his occasional lapses add piquancy to his always racy speech. It is a measure of his great-heartedness that he was able to turn these errors of speech into a joke embarrassing neither to his friends nor to himself. He had a rare sympathy and the widest of interests. It is primarily these that made him the successful teacher that he was, though his excellent text-books show the clearness of mind that is also essential. Few men have made so many friends and so few enemies.

In his researches on ionization Eve showed ability in handling the primitive apparatus of the day and in making clear and logical deductions. Reading them in the light of after-events, it is tantalizing to see how near he came to the discovery of cosmic rays. Though the ionization over land agreed reasonably well with what must be caused by traces of emanation and other known radioactive effects, all of which he carefully measured, it was difficult to account for the ionization over sea. This difficulty he clearly states, and perhaps if he had had more opportunities for measurements at sea he would have proved the existence of another source of ionization.

His text-book "College Physics", written in collaboration with Mendenhall and Keys and recently revised, is still widely used.

Eve was one of the first physicists of distinction to concern himself with the use of physical methods in prospecting in the nineteen-twenties. He published a series of papers, with D. A. Keys and others, dealing especially with the electrical and magnetic methods, and his influence was important in promoting the use of geophysics in Canada. His book on the subject, with D. A. Keys, is an admirable exposition well adapted for men with only a moderate knowledge of physics.

In 1905 he married Miss Elizabeth Brooks of Montreal. She survives him, as do one son and two married daughters.

G. P. Thomson

Dr. J. G. Parker

Dr. James Gordon Parker died on April 30 at his home in London in his seventy-ninth year. He was born on August 30, 1869, at Newport, Fife, and received his early education at the Madras College, Scotland, and then proceeded to Owens College, Manchester. With this foundation, he went for periods to the Universities of Heidelberg and Göttingen, and thence to the University of Strassburg. It was from here that he received his degree of Ph.D. in 1891, the subject of his thesis being "Ueber Neue Synthesen mit Brenztraubensäure".

Family associations gave him an interest in the leather industry, and for a short time he went to the University of Leeds with the late Prof. H. R. Procter and worked in the Leather Industries Department. Then, to obtain some experience in Continental leather manufacture, he went to Germany for a few years (he spoke German fluently).

So well equipped, he was appointed head of the Herolds Institute, Bermondsey, the first tanning school in London, which was opened in 1897. He remained here until 1909, when the school was transferred to the newly erected Leathersellers' Technical College, Tower Bridge Road, S.E.1, and he was principal of the College from that date until 1928, when he retired. He was elected a fellow of the Royal Institute of Chemistry in 1909. On retirement, he continued in private practice as a consulting chemist to the leather industry, and was internationally known as an authority in this branch of chemical technology.

During the First World War, Dr. Parker was appointed a member of the Leather Supplies Committee at the War Office, and of the Allied Commission of Supplies, where his experience was placed freely at the disposal of the Government. For many years he was examiner in leather manufacture for the City and Guilds of London Institute. During the period 1914–18 he was also honorary secretary of the London Tanners' Federation and the United Tanners Federation. He was an honorary liveryman of the Worshipful Company of Leathersellers, and held the Order of Leopold (second class) and the Order of the Crown of Italy. In 1904 he was awarded the Silver Medal of the Royal Society of Arts for his investigations into the causes of the deterioration of bookbinding leathers.

Dr. Parker will be best remembered for his work in the formation and development of the International Association of Leather Trades' Chemists. The Association was formed in 1897, and at the time of his death he was one of the two remaining original members. That Association later developed into the International Society of Leather Trades' Chemists, with sections in many parts of the world (the Society was recently dissolved with the formation of autonomous societies and an international Union). He was the first secretary of the Association, and remained so until 1912, when he was elected president for the years 1912–14. He was awarded the Association's Gold Medal in 1912. After the First World War, he was elected president of the then newly formed International Society for 1920–21, then treasurer for a period, and finally honorary secretary from 1929 until a year or so ago, when ill-health compelled him to forgo many of his activities. He was elected an honorary member of the Society in 1934.

Dr. Vaughan Cornish

Dr. Vaughan Cornish was a son of the vicarage, one of the most valuable groups in our national life, and his father's articles on Nature in south-eastern England in the late nineteenth century are still remembered for their intrinsic value and the beautiful form in which they were given. Dr. Cornish therefore had a good heritage of a kind he was to develop by his own efforts to understand, and to spread the understanding of, natural beauty. He was born in 1862 when his father was vicar of Debenham, Suffolk. After attending St. Paul's School, he studied chemistry at the University of Manchester, ultimately taking the D.Sc. degree and becoming director of technical education under the Hampshire County Council. In 1891 he married Ellen Agnes Provis and, with her, planned travel and research. His earlier researches, continued throughout life, were on waves —of water, snow and sand, on sea beaches, sandbanks, sand-dunes and snowdrifts. The Royal Geographical Society recognized his work by giving him the Gill Memorial Award in 1900. Earthquake waves were also studied in Jamaica in 1907, when both Dr. and Mrs. Cornish were injured; and the results of the inquiries were published in the *Geographical Journal* of 1912. In 1903, Dr. and Mrs. Cornish went around the world, making a special study of Japan, and later on they paid several visits to Panama to study the Canal while it was under construction. In 1911, Mrs. Cornish died and her husband some time afterwards published "The Travels of Ellen Cornish" as a tribute to her memory.

During the First World War, Dr. Cornish did a great deal of lecturing on strategic geographical questions to groups of officers in all branches of the Services, and thereby developed his interest and understanding of many matters of environmental conditioning of social and political life, the political side being more prominent in his mind and work. One of his best known books is "Great Capitals", with its analysis of the situations of capitals in their relations with the country concerned in each case. Dr. Cornish was a well-known and frequent contributor to the work of the British Association for the Advancement of Science, and in 1923 was president of Section E (Geography) of the Association. He was also a faithful friend of the Geographical Association and occupied its presidential chair. One remembers the distinguished figure wandering around at meetings looking for some fine piece of architecture, or some gem of natural scenery to be sketched and studied and discussed from an æsthetic rather than from a historical point of view. He gave much thought to the work of the Council for the Preservation of Rural England and wrote for it "The Scenery of England" (1932); but his most personal interest was in trying to use æsthetics as a channel of approach to truth. "The Poetic Impression of Natural Scenery" (1931) is but the best known of his many efforts in this field. If one cannot point to any very definite doctrine of his concerning æsthetics, we can appreciate, perhaps all the more, the spirit of the searcher after truth who had learned from a scientific training that truth is too great to need propagandist crutches.

Dr. Cornish's second wife was Miss Watson, who was the widow of Mr. E. A. Floyer. In his later years Dr. Cornish derived much pleasure from the inheritance of South Combe farm on which is Salcombe Hill, Devon. He gave this hill-top to the public and supported efforts to protect public amenities in Devon.

We regret to announce the following deaths:

Prof. W. T. David, professor and head of the Engineering Departments of the University of Leeds, on May 22, aged sixty-two.

Mr. G. L. Overton, formerly a member of the staff of the Science Museum, London, on May 22, aged seventy-two.

Dr. G. H. Pethybridge, O.B.E., formerly mycologist to the Ministry of Agriculture and Fisheries and assistant director of the Ministry's Plant Pathology Laboratory, Harpenden, Herts, on May 23, aged seventy-six.

Mr. J. J. Shaw, C.B.E., who maintained his own seismological observatory at West Bromwich, on May 23, aged seventy-four.

NEWS and VIEWS

Royal Botanic Gardens, Kew: Dr. N. L. Bor, C.I.E.

DR. NORMAN LOFTUS BOR, who was recently appointed assistant director of the Royal Botanic Gardens, Kew, had a distinguished career at Trinity College, Dublin, and the University of Edinburgh, and was awarded his doctorate for a thesis on the "Synecology of the Naga Hills". He has had wide experience in forest and general administration in the Indian Forest Service during 1921–46. He was political officer of the Balipara Frontier Tract during 1931–34, deputy commissioner of the Naga Hills in 1935 and acting inspector-general of forests in 1939. During 1942–46 he held a responsible position in relation to evacuation, reconstruction and rehabilitation on the North-East Frontier. He has travelled extensively in India and the Near East. During 1937–42 he was forest botanist at the Forest Research Institute, Dehra Dun, and in recent years has carried out research on the Indian species of the Gramineæ. Dr. Bor's published botanical works deal with the taxonomy of Indian plants and with the ecology of Assam and the Nilgiri Hills. In particular, he has concentrated on the study of grasses and has described new species from various parts of India. Recently, at Kew, he has made a detailed study of the Indian species of *Poa.*

National Museum of Wales: Sir Cyril Fox, F.B.A.

IT is sad to realize that the time has come for Sir Cyril Fox to retire from the post of director of the National Museum of Wales. The old saying may be true, "Le roi est mort, vive le roi", but his successor will find it no light matter to continue Sir Cyril's distinction as a researcher and his efficiency as an administrator. Fox was educated at Christ's Hospital and Cambridge. He was always an ardent archæologist, even in the days of long ago (1912–24) when at Cambridge he occupied the post of superintendent of the University Field Laboratories. Indeed it was at this time that his great work, "The Archæology of the Cambridge Region", which gained him his Ph.D., was written and published, and that he did so much splendid voluntary work for the Cambridge Museum of Archæology and Ethnology, where his beautiful lettering on the labels of things he arranged is still admired. In 1924 he was elected a Kingsley Bye-Fellow of Magdalene College, and later—after his nomination to the directorship of the National Museum in Dublin by the Irish Academy had been refused by the then Irish Civil Service on the grounds that he was an Englishman—he became a keeper and lecturer in the National Museum of Wales, of which he was soon to become the director. Sir Cyril has, not unnaturally, been president of a number of archæological societies, and has published regularly the results of his researches. His most thought-productive work, perhaps, has been "The Personality of Britain", which has passed through no less than four editions. There are other archæologists who can claim a high degree of scholarship and achievement, but few who can inspire and charm as does Sir Cyril Fox; to be with him is indeed an inspiration. The best wishes of all go to him in his retirement at Exeter, where his wife is lecturing and where we may be sure he will have retired only from administration, and will doubtless pursue his researches with continued zest and a freer mind.

Mr. D. Dilwyn John

MR. DAVID DILWYN JOHN, who is succeeding Sir Cyril Fox as director of the National Museum of Wales, is a graduate of the University of Wales. He served as a zoologist on the staff of the *Discovery* Investigations during 1925–35, making three voyages to the Antarctic, and was later awarded the Polar Medal. In the course of one of these commissions, while he was in charge of the scientific work, the first winter circumnavigation of the southern continent was made. His researches into the development and distribution of southern Euphausiidæ, based on material much of which he had himself collected, resulted in a report which is a fundamental contribution to our knowledge of the natural history of these important Antarctic crustaceans. On appointment to the British Museum (Natural History) in 1935, Mr. John was put in charge of the collections of Echinoderms, and his principal publications in recent years have been related to the subject of his specialization. In particular, he has concentrated on collections of Crinoidea made by such expeditions as the *Discovery, Scotia, Belgica* and the British, Australian and New Zealand Antarctic Expedition in high latitudes, and besides the taxonomic results obtained, themselves of great value, he has thrown much interesting light on viviparity in the Crinoidea and the care of the brood by the parent animal. A Territorial Army officer prior to the War, he was on military service until 1946; he became a deputy keeper in the Department of Zoology in February of this year.

World Co-operation in Science

PROF. J. D. BERNAL's recent presidential address to the Association of Scientific Workers contains some points which merit the notice and support of all scientific workers. He directed attention to the danger which retarded capital expenditure involves to industrial development and research, and also to the consequences to scientific effort if the reconstruction plans of the universities and research laboratories should be curtailed or postponed. He emphasized that neglect and waste of resources, both material and human, continue, and quoted Sir Henry Tizard's statement to the Parliamentary and Scientific Committee that on existing knowledge productivity could be raised by fifty per cent. As he very truly remarked, the hope of Great Britain, economically, culturally and scientifically, lies in the extent of its links with all other countries, with the United States no less than with Soviet Russia, with Eastern no less than Western Europe, and with the Colonial peoples. The world requires the flourishing of science as a basic condition of human happiness, even of human life itself; but scientific men by themselves form a weak minority, and can only be effective if they associate themselves with all others who have a common will for reconstruction and peace. Much of Prof. Bernal's address, however, was an attack on the Marshall plan for aid to Europe and the Government's policy of removing communists from key positions in defence research which ignores both the totalitarian threat to the freedom of science in Soviet Russia and the question of loyalties which has compelled Government action in Britain against communists.

Higher Technological Education in Britain

THE University Grants Committee has appointed a sub-committee to advise it on matters affecting technology in the universities of Great Britain, and to consider questions of higher technological education in consultation with the National Advisory Council on Education for Industry and Commerce, appointed by the Ministry of Education. The sub-committee consists of: Dr. A. E. Trueman (chairman), Prof. J. F. Baker, Sir Alan Barlow, H. W. Cremer, Sir Charles Darwin, Sir Peter Innes, Prof. Willis Jackson, Sir Andrew McCance, Prof. Andrew Robertson, Prof. J. B. Speakman, Sir Raymond Streat, Sir Henry Tizard, and Sir Charles Ellis.

B.C.U.R.A. Quarterly Gazette

THE *B.C.U.R.A. Quarterly Gazette*—a new publication of the British Coal Utilization Research Association—is designed to give a more colourful account of the Association's work and to serve a wider range of readers than a rigorously scientific journal. To factual accounts of research and development projects, it will add a running commentary on the Association's staff and their activities. The circulation will not be limited to members only. The first number contains a survey by Sir Charles Ellis, president of the Council, as it finds itself in a nationalized coal industry, covering its members, staff, accommodation, work and prospects. There follow articles on technical achievements in course of development. B.C.U.R.A. Patent No. 1 describes the down jet furnace, which employs a revolutionary system of combustion of solid fuels. Normal combustion on a grate is beset by limitations owing to the presence of ash and volatile matter in the fuel. These are avoided by the new technique, which provides freedom to work at greater intensities and for longer durations. The exploitation of these ideas is only in its infancy. Another item deals with the Association's work on domestic heating by open coal fires, which normally radiate not more than 25 per cent of the heat of combustion. Work in past years has shown the possibility of increasing this by one or other method—especially by supplementing radiation with heat convection. To-day the consumers' progress towards fuel economy is limited by lack of availability of efficient appliances. Sometimes these are too costly or even only to be obtained in a new house. The article describes a new inset fire which can be fitted into an existing grate at a moderate cost. It is designed by Mr. J. S. Hales and Mr. T. W. Grieve and claimed to be capable of high thermal efficiencies. When burning normal house coal, the total output of heat—by radiation and convection combined—reached 37 per cent; with coke, the figure reached 48 per cent of the heat of combustion. In addition, by reducing the flow of heat up the chimney to one change per hour, draughts are minimized and comfort improved.

Medical Group Practice in the United States

THE review of the development and characteristics of Medical Group Practice in the United States which Political and Economic Planning has issued as Broadsheet No. 274 is of special interest in view of the obligations placed on local authorities in Britain under the National Health Service Act to provide, equip and maintain health centres staffed and run by medical practitioners working as a team. The survey shows that American group practice aims at providing a full general and specialist service, including, if possible, in-patient treatment, and in the United States the term is applied to almost any form of organised medical team-work. The main incentives appear to be the inability of individual practitioners to provide a sufficiently complete service, the desire for professional co-operation among medical men and the need to reduce the cost of medical care by decreasing overhead expenditure and bringing specialist and hospital services to undeveloped areas. The main criteria are organised team-work and pooling of income. Day-to-day consultations are supplemented by staff meetings, good record systems, and sometimes also by democratic methods of administration. Groups show much interest in keeping their members up to date and developing their skills, for example, by good libraries, paid annual study leave, and systematic training of junior members. Financial competition within the group not only hinders team-work but also results in friction, and no solution has yet been found for the problem of assessing financially the diverse and constantly changing ability of physicians. The election of group members is of the highest importance and should be done by the medical men themselves. Some are temperamentally unsuited for group work and should be excluded. Good group practice may have a beneficial influence on medical standards over a wide area; but in view of the important differences in social background, in the development of health services and in the organisation of the medical profession in the United States, careful consideration will be necessary before the lessons of American experience can be applied to Britain.

British Trust for Ornithology

THE work of the British Trust for Ornithology (91 Banbury Road, Oxford) is described in the fourteenth annual report which has recently been issued. Much useful information has been collected from the hatching and fledging inquiry and will be included in the new edition of the "Handbook of British Birds". A sample census of heronries showed that large decreases were recorded in every considerable area and in the majority of individual heronries; this was almost certainly due to the extreme severity of the winter. The black redstart inquiry showed that, up to the end of the year, sixteen pairs were reported to have lived in the south of England. Other inquiries have been made into the behaviour of tits with milk-bottles and the nocturnal activities of redwings; but probably the most popular was the watch for swifts on May 11, 1947. Five hundred observers made reports on the movements of about five thousand birds, three out of every four of whom were headed north. Above a line drawn from the Wash to the Severn this northward surge was especially marked, and in south-west Devon several parties of swifts were seen to come in from the sea and to proceed inland.

Megalithic Tombs in Scotland and Ireland

PROF. GORDON CHILDE'S present ideas on the Megalithic tombs in Scotland and Ireland are put on record in a paper read before the Glasgow Archæological Society (*Trans.*, **11**; 1947). Recent discoveries have caused him to modify some details of his exposé made in the same publication for 1931. No longer, for example, is "the priority of Scottish passage graves over against English or Irish" maintained. The chief discoveries made in the last ten years have been those of no less than seventy horned cairns covering segmented cists in Ulster which, allowing for local differences, can be equated with the tombs of the Clyde and Solway coasts. Beacharra ware occurs in both these series of tombs. Further, it would appear that in Megalithic tomb times, south-west Scotland, north-east Ireland and the Isle of Man formed one province, while central and western Ireland and Scotland north of the Great Glen constituted another. Lastly, Prof. Childe uses the new discoveries to suggest an explanation of the anomalous occurrence of long cairns, horned at both ends, which have been found in northern Scotland.

Raffles Museum, Singapore

THE *Bulletin of the Raffles Museum* was suspended in 1941 when the Japanese occupied Singapore. It has now been revived, and the first issue of the new series (No. 18, October 1947) is made up of papers prepared before the occupation and preserved in the Museum. It is devoted almost entirely to the natural history of Christmas Island in the Indian Ocean and based on collections and field notes made on the island by C. A. Gibson-Hill between September 1938 and November 1940. Much of the bulletin describes the birds of the island; but notes are also included on the nature of the coast, climatic conditions from July 1939 to June 1940, echinoderms, Brachyura, terrestrial crabs, Arachnida, Isoptera, heterocerous and rhopalocerous Lepidoptera, terrestrial reptiles and mammals. The *Bulletin* also contains an obituary notice of the late director, F. N. Chasen, who was killed by enemy action in 1941.

Textile Institute: Annual Conference

THE subject of the annual conference of the Textile Institute, to be held at Buxton during June 2–5, will be "The Organisation of the Textile Industry". Among the authors of papers are Sir William Palmer (chairman, British Rayon Federation), Dr. F. C. Toy and Dr. D. W. Hill (British Cotton Industry Research Association) and Prof. A. N. Shimmin and Prof. A. J. Brown (University of Leeds). The Institute will also discuss its own role in the organisation of the industry at the opening session on June 2, when chairmen of its various committees will describe the work of their sections and their plans for the future, dealing in particular with education, standardization, publication, co-ordination, liaison and the status of the textile technologist. Foreign visitors to the conference include B. Hellmann and Dr. Zoltan Szaloki, who are to present a paper on "Textile Planning and Modernization in Czechoslovakia". Mr. Harold Wilson, President of the Board of Trade, has agreed to address the conference on June 2.

Science Service Officers

DR. KARL LARK-HOROVITZ, chairman of the Department of Physics, Purdue University, Lafayette, Indiana, and Charles E. Scripps of Cleveland, Ohio, have been elected trustees of Science Service, of Washington. Mr. Scripps represents the E. W. Scripps Estate, of which he is a trustee, while Dr. Lark-Horovitz represents the American Association for the Advancement of Science, of which he is general secretary. The following officers have been re-elected: *President*, Dr. Harlow Shapley, director of Harvard College Observatory; *Vice-President and Chairman of the Executive Committee*, Dr. Alexander Wetmore, secretary of the Smithsonian Institution; *Treasurer*, O. W. Riegel, director of the Lee School of Journalism, Washington, and Lee University, Lexington, Virginia; *Secretary*, Mr. Watson Davis, director of Science Service, Washington, D.C. Additional members of the Executive Committee are Mr. Frank R. Ford, editor of the Evansville Press, Evansville, Indiana; and Dr. E. G. Conklin, Princeton University, Princeton, New Jersey.

British Medical Association: Annual Scientific Meeting

THE first annual scientific meeting of the British Medical Association since the War will be held at Cambridge during June 25–July 2, under the presidency of Sir Lionel Whitby, regius professor of physic in the University. Among the topics of particular scientific interest announced for discussion are: recent advances in knowledge of the *Rh* factor in blood; plasma and blood derivatives in the treatment of burns; human relations in industry; prophylaxis of virus infections; radioactive isotope therapy; aviation medicine; nutrition; antihistamine substances.

International Summer School in Social Biology

THE British Social Hygiene Council is organising a Summer School on "The International and Cultural Relations of Social Biology", at the University, Lausanne, Switzerland, during August 18–September 1. During the first week of the School, there will be two morning and one evening lecture sessions each day, except Sunday, while the second week will be free for visits, excursions, and personal recreation. The course is intended for students of biology, teachers, social workers, men and women in administrative positions, and all who are interested in problems of human welfare and culture. The estimated cost, including travel, hotel accommodation and tuition, will be about £35. Further information can be obtained from the Secretary, British Social Hygiene Council (Dept. S.J.1), Tavistock House North, Tavistock Square, London, W.C.1.

Summer School in Health Education

THE Central Council for Health Education is holding its annual Summer School in Health Education at 'High Leigh', Hoddesdon, Hertfordshire, during August 11–25. In addition to the basic lectures in physiology (by Prof. Samson Wright), psychology (by Prof. James Drever), the biology of infection (by Dr. Robert Cruickshank), and social factors affecting health (by Prof. J. M. Mackintosh), Dr. H. A. Wilson, the Bishop of Chelmsford, will speak on "The Spiritual Needs of Man", and Sir Alexander Fleming on "Penicillin". An interesting new development is that of a course of nature study, with rambles and evening discussions, illustrated by films, strips and bird-song records. The School will appeal especially to educational and medical administrators, doctors, teachers, youth leaders, public health nurses, industrial nurses, industrial welfare workers, training organisers and students. Further information can be obtained from the Medical Adviser and Secretary, the Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1. The inclusive cost of the course per person will be £16 16*s*.

Conference on Individual Freedom and Social Responsibility

THE tension between society and the individual was emphasized by more than one speaker at the Ethics and Science Conference organised by the British Social Hygiene Council in March this year. This conflict, recurrent in every age, but particularly acute in our own, was felt to be one meriting closer examination than was possible at the time, and for this reason another Ethics and Science Conference has been arranged for Thursday, June 10, when the subject will be "Where does Freedom End ?" On one hand, the individual is faced with certain obligations towards the community—obligations which seem to increase in number with the growth of the welfare State. On the other hand, there is the urge to self-expression, which only too often appears to conflict with man's social responsibilities. The need for reconciling these two principles is present in every department of life, but is nowhere more clamant than in the spheres of home and work. The Conference will therefore concentrate on these two aspects of the problem, Canon V. A. Demant, of St. Paul's Cathedral, dealing with the first, and Prof. T. S. Simey, professor of social science in the University of Liverpool, with the second. The Conference will take place in the Livingstone Hall, London, from 2 p.m. until 5.30 p.m., and ample time will be allowed for discussion. Tickets (price 2*s.* 6*d.*) and further information may be obtained from the Secretary, British Social Hygiene Council (Dept. S.J.1), Tavistock House North, London, W.C.1.

Conference on the Overseas Territories of Western Europe

A STUDY Conference on the Overseas Territories of Western Europe is to be held in the Indisch Institut, Amsterdam, under the joint auspices of the Allied Circle, Amsterdam, and the British Society for International Understanding, during June 9–12. The purpose of the Conference is to study in their widest aspects the implications for the Overseas Territories of the union which is in process of formation between the countries of Western Europe ; to promote mutual understanding of the actual conditions, needs and possibilities of the countries for whose well-being the British, French, Belgian, Netherlands and Portuguese Governments are responsible outside Europe ; to learn what steps have been taken or could be taken to develop collaboration between them in the spheres of economics, social welfare and security, and to consider the education of public opinion upon this important subject. Further information can be obtained from the Secretary, British Society for International Understanding, Benjamin Franklin House, 36 Craven Street, London, W.C.2.

The Night Sky in June

NEW moon occurs on June 7d. 12h. 55m., U.T., and full moon on June 21d. 12h. 54m. The following conjunctions with the moon take place : June 8d. 23h., Mercury 4° S. ; June 9d. 04h., Venus 3° S. ; June 11d. 17h., Saturn 4° S. ; June 13d. 08h., Mars 4° S. ; June 21d. 01h., Jupiter 4° N. In addition to these conjunctions with the moon, Mercury is in conjunction with Venus on June 30d. 19h., Mercury being 1·0° S. Mercury is an evening star at the beginning of the month, but towards the middle of the month is too close to the sun for favourable observation, and is in inferior conjunction on June 24. Venus is conspicuous in the western sky, setting at 22h. 35m. and 21h. 10m. on June 1 and 15 respectively, and is in inferior conjunction on June 24. Mars is still visible as an evening star, setting at 0h. 48m. and 23h. 15m. at the beginning and end of the month respectively, and Saturn, which is fairly close to Mars, sets on the corresponding dates shortly after midnight and 22h. 22m. respectively. Jupiter, in opposition on June 15, is visible throughout the night, but is rather low for good observation in northern latitudes. No occultations of stars brighter than magnitude 6 occur in June. Summer solstice occurs on June 21d. 12h.

Announcements

THE RIGHT HON. SIR STAFFORD CRIPPS has been elected a fellow of the Royal Society under Statute 12 of the Society, which provides for the recommendation by the Council of persons who "have rendered conspicuous service to the cause of science, or are such that their election would be of signal benefit to the Society".

PROF. E. O. LAWRENCE, professor of physics and director of the Radiation Laboratory, University of California, Berkeley, has been elected an honorary fellow of the Physical Society.

THE following have been elected officers of the Royal Aeronautical Society for the year 1948–49 : *President*, Dr. H. Roxbee Cox ; *Past Presidents*, Sir Frederick Handley Page, Sir A. H. Roy Fedden ; *Vice-Presidents*, Sir John Buchanan, Mr. W. G. A. Perring, Mr. N. E. Rowe ; *Hon. Librarian*, Mr. J. E. Hodgson ; *Hon. Treasurer*, Captain C. F. Uwins ; *Secretary*, Captain J. Laurence Pritchard

IN connexion with the next General Assembly of the Union Radio Scientifique Internationale, to be held at Stockholm in July (*Nature*, May 1, p. 695), Unesco is contributing 3,000 dollars to the travelling expenses of the official members of the Union who will attend the meeting, and another 3,000 dollars to the publication of the report of the General Assembly.

A SYMPOSIUM on "The Genetics of Cancer", organised by the Genetical Society of Great Britain and the British Empire Cancer Campaign, is being held during June 24–25 in London. Among the topics to be discussed are inheritance of cancer in animals ; virus- and carcinogen-induced mutations ; inheritance of cancer in man. A number of American, Continental and British scientific workers will read papers. The meetings will be open to all interested in the subject. Further particulars can be obtained from Dr. R. R. Race, Lister Institute, Chelsea Bridge Road, S.W.1.

THE Committee of the Challenger Society has received a grant from the Development Fund to assist in paying the expenses of certain oceanographers attending joint meetings arranged by the Society. It is not available for members of State-aided institutions, nor can it be used for undergraduates. It may be used for others than members of the Challenger Society. Grants from the fund will consist of third-class travelling fare and a daily subsistence allowance. The awarding of grants rests with the Committee of the Challenger Society. The number for one meeting is likely to be limited to five or six. Applications for grants for a meeting to be held at the Fisheries Laboratory, Lowestoft, on July 8 and 9 should be submitted to the Honorary Secretary, Challenger Society, British Museum (Natural History), Cromwell Road, S.W.7, before June 15.

Anomalous Distribution of Nuclear Disintegration in Photographic Emulsions Exposed to Cosmic Rays: Double Stars

IN making systematic exploration of 640 cm.^{2} of Ilford plates of 100 μ thickness exposed vertically to cosmic rays for three to six weeks at a height of 3,600 m., we have observed 2,250 nuclear disintegrations and have noticed an anomaly in their distribution.

The accompanying table indicates the number p of observed pairs of stars for which the distance between the centres is less than R microns, the probable number P of the stars which would be observed with random distribution, and number of standard deviations r separating the observed value from the mean value.

R	50	100	150	200	250
P	0·15	1·2	5·0	10·3	17·3
p	4	10	17	24	33
r	10	8	5	4	4

For example, chance would lead one to expect 1·2 pairs with a centre distance less than 100 μ, yet we have observed 10 pairs; in this case the number of standard deviations from the mean value is 8.

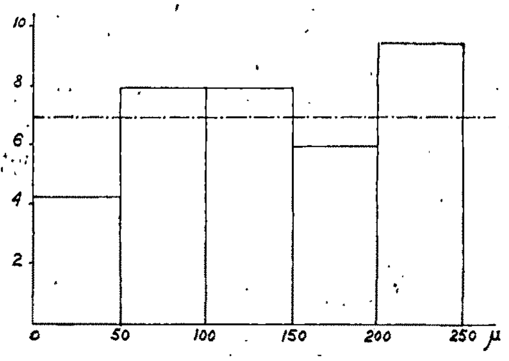
The simplest explanation of the anomaly is to suppose that one of the stars of the pair has produced the other through the medium of a particle which is invisible in the emulsion (neutron, neutral meson, photon, electron, fast proton, or fast charged meson). It is not possible to evaluate the energies and momenta carried by such intermediate particles from our present data, for we are unable to distinguish *a priori* a fortuitous pair from a real one; neither could we distinguish the primary star from the secondary (except three cases in which one of the stars is due to a σ-meson). Furthermore, the measurements with photographic emulsion involve many uncertainties, such as the nature of the disintegrated nucleus, nature of short tracks, distribution of emitted neutrons.

However, it is possible to get an idea of the order of magnitude of the cross-section of this intermediate particle by the following reasoning. The probable number of random pairs with their centre distance between R and $R + dR$ is

$$A.2R^2/h.dR, \text{ if } R \ll h; \quad A.3h/8.dR, \text{ if } R = h/2; \quad A.RdR, \text{ if } R \gg h;$$

where h is the thickness of the emulsion.

$A = \pi \Sigma N_i^2/S_i$, where N_i is the number of stars in the ith plate, S_i its surface, $i = 1 \ldots . 30$.



If we subtract from the observed number of pairs those due to chance as calculated above, and if we take into account the pairs which are not observed since the thickness of the emulsion is very small (by multiplying the result by $k(R) = 1$ if $R \ll h$; or $2 \log 2$ if $R = h/2$; or $2R/h$ if $R \gg h$) we shall get the number of non-fortuitous double stars in an emulsion, which is now presumed to be very thick, as a function of the distance separating the centres, say, from 50 μ to 250 μ.

If we assume that each star emits on the average b particles able to produce a secondary star, we get for the order of magnitude of the cross-section

$$\sigma = \frac{1}{nM}\frac{dn}{dx} = \frac{7 \cdot 5}{b} \times 10^{-24} \text{ cm.}^2,$$

where $M = 8 \cdot 5 \times 10^{22}$ is the number of nuclei per cm.^{3} of emulsion; $n = 2{,}250$, b is the total number of 'asterogen' particles issuing from the stars of our plates; and $dn = 35 \cdot 75$ is the number of double stars deduced from the curve by setting $dx = 250\,\mu$.

This value of σ, for example, would be in accord with that of neutrons, for the stars emit on the average four to six protons; therefore the order of b can be assumed to be 5–10.

During the course of the present work, we have been in close touch with D. H. Perkins, whose results are given in the following letter. We thank G. P. S. Occhialini, C. F. Powell, and C. M. G. Lattes for their friendly advice concerning the method; we are indebted to T. F. Hoang, L. Jauneau, J. Stroumsa and D. Morellet of the Laboratory of the Ecole Polytechnique for their assistance in the experiments.

L. LEPRINCE-RINGUET
J. HEIDMANN

Laboratoire de Physique
de l'Ecole Polytechnique,
Paris.

MEASUREMENTS have been made on the surface distribution of 1,230 stars on 54 sq. in. of 100 μ C2 plates loaded with boron, exposed for 40 days at 3,650 m. elevation. Observations on the star frequency in 1 in. × ½ in. rectangles of plate area show that, by comparison with the appropriate Poisson distribution, the stars are randomly distributed over areas of these dimensions.

The distances between forty-seven close pairs of stars have been obtained; the projection, r_p, of the separation between the star centres, in the plane of the emulsion, is $r_p^2 = x^2 + y^2$, where x and y are the differences between the surface co-ordinates of each pair. If the distribution were random, the probable number of stars, out of the total observed, within distances r_p of other stars, should be $\pi r_p^2 N . N/A$, where A is the area of plate from which the total of N stars are taken. The probable number of pairs, separated by distance r_p or less, is therefore

$$Q = \tfrac{1}{2}\pi r_p^2 \frac{N^2}{A},$$

provided $Q \ll N$.

As can be seen from the accompanying table, the observed number of pairs P is considerably greater than the expected number Q, and the ratio $(P - Q)/\sqrt{Q}$ of the observed to the expected deviations is always greater than one.

Assuming the volume distribution of stars to be uniform, the actual mean separation r between the centres of pairs can be calculated in terms of the projected separation r_p, and values of r are given in the second row of the table.

r_p (1/100 in.) r (μ)	0·25 67	0·50 131	0·75 191	1·0 254	1·5 381	2·0 508	2·5 635	3·0 762
P	2	4	6	8	16	28	40	47
Q	0·27	1·10	2·48	4·4	9·9	17·6	27·5	39·6
$(P - Q)$	1·7	2·9	3·5	3·6	6·1	10·4	12·5	7·4
$(P - Q)/\sqrt{Q}$	3·3	2·8	2·2	1·7	1·9	2·5	2·4	1·2
$B = R/q\sigma \times 10^{24}$	0·38	0·60	0·73	0·83	0·97	1·05	1·14	1·21
$(P-Q)/B = q\sigma \times 10^{24}$	4·5	4·8	4·8	4·3	6·3	9·9	11·0	6·1

If we consider the surplus of double stars to be produced by infinitely penetrating radiation from the primary stars producing secondary stars, we can easily calculate the variation of the double stars with distance r. Let q be the number of particles from each star, σ the cross-section of each for producing a further star. Then, assuming the particles to be emitted isotropically, the number of 'doubles' with separation less than r is

$$R = Nq\sigma L \,.\, \left[\frac{3d}{4} + \frac{d}{2}\log r/d\right] \text{ for } r > d$$

$$R = Nq\sigma L \,.\, [r - r^2/4d] \text{ for } r < d,$$

where d is the emulsion thickness and L is the number of nuclei per c.c. of emulsion. The most accurate analysis at present available gives $L = 5{\cdot}61 \times 10^{22}$ for the boron-loaded Ilford emulsions (neglecting the hydrogen content).

Hence we obtain for a mean value

$$q\sigma \times 10^{24} = 6{\cdot}5 \pm 2{\cdot}4.$$

If the invisible secondaries are assumed to be fast neutrons, $\sigma \sim 10^{-24}$ cm.^{2} and hence $q \sim 6{\cdot}5$. This requires every star to emit about six neutrons, each with sufficient energy to produce a second disintegration. The average number of protons emitted in stars in our plates is slightly more than three, with an average energy of 10 MeV. each. Since the disintegrations must liberate roughly equal numbers of neutrons and protons, and the energy required to produce a second disintegration must be at least 30 MeV., our conclusion is that only a fraction of the secondary stars are, in fact, produced by neutrons from the primaries. In the batch of plates from which these measurements were taken, we observed only one definite case in which a disintegration liberated a charged (σ) meson giving rise to a second disintegration. Hence the number of neutral mesons emitted in the disintegrations may be quite small, and if these are responsible for the regenerative processes, we should have to postulate very large nuclear capture cross-sections.

It is possible, however, that the pairs are produced by single penetrating particles, or by collimated showers of particles of unknown type. The variables in such a process could easily be chosen so as to give the observed variation of pair frequency with r.

The value of $q\sigma$ we have obtained agrees very well with that of Leprince-Ringuet and Heidmann in the previous communication. We are indebted to Prof. Leprince-Ringuet for so kindly exposing our plates in his laboratory at Chamonix, and for communicating to us his results prior to publication. Our thanks are also due to Sir George Thomson for valuable discussions and advice.

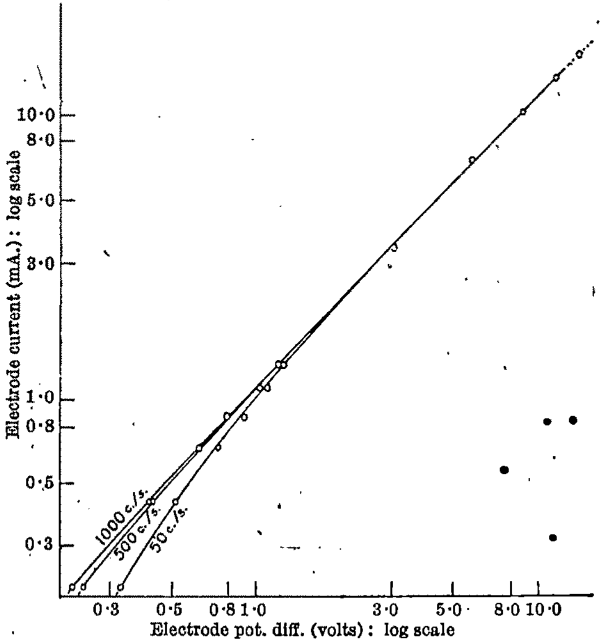
An Electrolytic Tank for Exploring Potential Field Distributions

Two difficulties have commonly been experienced in the exploration of potential distributions in electrolytic tanks, when alternating current is used: (*a*) non-linear conduction due to polarization at the electrode surfaces[1], which becomes serious at very low potential differences or currents, and (*b*) corrosion of the electrodes causing the conducting path to assume a leading power factor[2], which increases with increasing current density. Both effects are greatly reduced by raising the working frequency; but they are incompatible with one another if very fine probe electrodes are used. The effect of frequency on the non-linear conduction is illustrated in the accompanying diagram.



In a series of studies using solutions of copper sulphate in distilled water of concentration varied between 0·5 and 8·0 gm./litre and copper electrodes of various diameters, we have found that very accurate results are obtained with a measuring frequency of 1,000 c./s. and electrodes 0·5 mm. diameter, provided that the current per electrode is not less than 5 mA. or the current density does not exceed 0·3 mA./sq. mm. (by adjusting electrode depth). These results apply throughout the range of concentration quoted.

For such fine electrodes, steel sewing needles which have previously been plated by the copper cyanide process, being rigid, are particularly suitable. The current density used during the plating process has been 0·3 mA./sq. mm. for the first 5 min. and 0·015 mA./sq. mm. for a further 20 hours. This affords a polished copper surface 0·04 mm. thick. The plated needles have then been immersed in boiling acidified copper sulphate solution for a few minutes to coarsen and stabilize the copper crystals.

Alongside these studies, attention has been given to removal of errors due to the finite tank boundary, which can limit seriously the usable fraction of the electrolyte surface. A circular shallow tank, 18 in.

diameter, has been used, divided into two equal layers ½ in. deep, by a glass disk held at half the depth of the electrolyte. The top liquid layer, in which the potential field to be explored is set up, is thus contiguous with the lower layer around the periphery and may be shown to be electrically 'matched', such that it simulates an infinite sheet of electrolyte. The measured error in potential at the extreme edge is less than ½ per cent.

Thanks are due to the Electro-Chemistry and Chemical Engineering Departments of this College for assistance and advice.

Electron Emission from Oxide-coated Cathodes under Electron Bombardment

The electron emission from thermionic cathodes of the alkaline-earth oxide-coated type when under electron bombardment has been investigated recently by Johnson[1] and by Pomerantz[2]. Johnson concluded that the secondary-electron emission produced by the bombardment changed little with the cathode temperature, that at 850° C. the maximum value, δ_m, of the secondary to primary ratio was about 5, and that the bombardment produced a temporary improvement in the thermionic activity of the cathode, which gave an 'enhanced thermionic emission'. Pomerantz, on the other hand, concluded that the secondary-electron emission increased exponentially with the cathode temperature, and deduced from extrapolation of the results obtained at lower temperatures that, at 850° C., δ_m exceeded 100. The effect which Johnson interpreted as "enhanced thermionic emission" was also observed; but that interpretation was not accepted. It has been suggested[3] that "enhanced thermionic emission" rather than secondary-electron emission enables the anode current in a magnetron to exceed the thermionic emission provided by the unbombarded cathode. The experiments the results of which are indicated below were designed to throw light on the disagreement in the conclusions of the above investigators regarding the temperature dependence of the secondary-electron emission, and on the nature of the "enhanced thermionic emission" effect.

The target cathodes used in the experiments were coated with various thicknesses of a standard barium–strontium carbonate coating mixture. The measurements were made in electron-gun type tubes, the primary electrons being focused on the target through a hole in the collector surrounding the target. The secondary-electron yield of each target was measured as a function of the energy of the bombarding electrons, of the thermionic activity of the target, of coating thickness, and of target temperature in the range 20°–850° C. At temperatures at which thermionic emission was appreciable, both the thermionic emission and the emission caused by the bombardment were collected by pulsed collector voltages, pulses of 5–100 microsec. duration being used. In respect of the pulsed collection of the thermionic emission, and in the use of high collecting voltages (up to 5 kV.), the measurements differed from those made by other investigators.

The experiments showed that the secondary-electron yield of the various targets when at room temperature increased with the energy V_P of the primary electrons, reached unity at V_P 35 ± 5 eV. and a maximum value δ_m at V_P 1,100 ± 100 eV. δ_m varied from target to target, and values as low as 4 and as high as 14 were observed. When the targets were heated, δ_m usually changed to some extent in the lower temperature range, but in the temperature range, up to 850° C., in which the thermionic emission was appreciable, all the targets gave values of δ_m between 5 and 10 independent of the temperature. Incidentally, targets coated by evaporation in vacuum, and on which the coatings were so thin that they appeared merely as tarnishings of the nickel bases, gave δ_m values of about 4 or 5 which were completely independent of target temperature in the range investigated, 20°–850° C.

The results obtained with target coatings of various thicknesses and of varying degrees of activation supported the view that the variation of δ_m with temperature in the lower temperature range was not of a fundamental nature but was due to disturbing effects resulting from the appreciable resistance of the coating at those temperatures. On this view it would appear that Pomerantz was not justified in extrapolating from the yield values he obtained at the lower temperatures in order to deduce yield values at temperatures about 850° C., for the cause of the variation at the lower temperatures would have had negligible effect at the higher temperatures.

No evidence was obtained of the effect which Johnson interpreted as "enhanced thermionic emission". The electron current released from each target by a given pulsed bombardment rose immediately (in less than a microsecond) to a value which remained constant during the bombardment and dropped to zero immediately after the bombardment, and the magnitude of this current changed little with the target temperature. It is possible that the effect observed by both Johnson and Pomerantz followed from the continuous collection of the thermionic emission from the targets in their experiments. Continuous collection of thermionic emission from an oxide cathode is known to lower its thermionic activity, partly through increasing the concentration of 'foreign' atoms on the surface. Reduction of this concentration by the bombardment could then cause enhancement of the thermionic emission. Another reason for the absence of the effect in the present experiments might have been the adequate elimination of disturbing space-charges by the high collecting voltages that were used.

Thanks are due to Mr. A. Sczaniecki for his help in one of the experiments. A fuller account of the investigations will be published elsewhere. The work was done at the Admiralty Signal and Radar Establishment, and permission to publish this communication is gratefully acknowledged.

Total Emission Damping

IN recent letters in *Nature*, C. N. Smyth[1], A. van der Ziel[2] and A. van der Ziel and A. Versnel[3] have reported measurements on the damping produced by a diode in the non-conducting state placed across a resonant circuit.

To investigate this subject mathematically, the following idealization has been employed. It is assumed that the thermionic electrons are all emitted with speed v_0 at right angles to the cathode surface, and that they are then acted upon by a constant retarding field E_R superimposed upon the small alternating field $E_S \sin(\omega t + \varphi)$. The time of flight of these electrons in the absence of the alternating field is then $2v_0/E_R\frac{e}{m} = T$, and the transit angle is $\theta = \omega T$. If E_S is small compared with E_R, it can then be shown that the damping conductance $1/R$ is given by

$$\frac{1}{R} = \frac{8V_0I}{V_R^2}f(\theta). \qquad (1)$$

In this equation V_0I is total power emitted by the cathode, that is, the product of the number of electrons emitted per second and the kinetic energy of each electron. V_R is E_RD, where D is the effective distance across which the constant fields E_R and E_S are assumed to act.

The interesting part of equation (1) is $f(\theta)$, which is

$$f(\theta) = \frac{1}{\theta^2}\Big[\Big(1 - \frac{1}{\theta^2}\Big) \{4(1 - \cos\theta) - 4\theta\sin\theta + \theta^2(1 + \cos\theta)\} + \{2(1 - \cos\theta) - \theta\sin\theta)\}\Big]. \qquad (2)$$

This may be compared with the corresponding function for the conducting diode, $F(\theta)$, where

$$F(\theta) = \frac{1}{\theta^2}[2(1 - \cos\theta) - \theta\sin\theta]. \qquad (3)$$

Graphs of $f(\theta)$ and $F(\theta)$ are shown in Fig. 1.

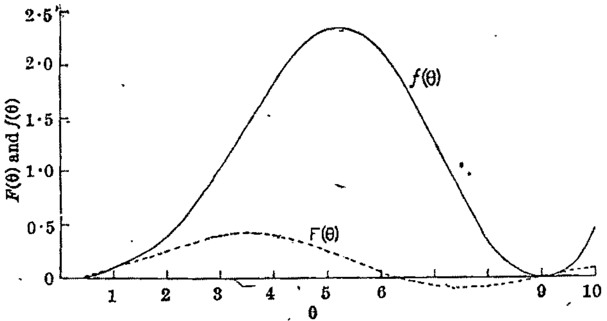

Fig. 1

That the absolute magnitude of the damping in equation (1) can be of the correct order of magnitude may be shown as follows. In Smyth's case[1], assume the values $V_R = 1$, $V_0 = 1/16$, both in volts, and $I = 1/10$ amp. per cm.^{2}. Then equation (1) gives $R = 20$ ohms per cm.^{2}. In van der Ziel's case[2], the damping is so small and the cathode-anode spacing is so large that it would be unwise to guess the value of V_R.

An interesting point emerges if equation (1) is written in the correct form to exhibit the variation of the damping with V_R, where V_R is assumed to be proportional to $1/\theta$. Then

$$\frac{1}{R} = \frac{I}{(\omega D)^2}\theta^2 f(\theta) = \frac{I}{(\omega D)^2}\frac{\theta^4}{9}$$

for small values of θ. The function $\theta^2 f(\theta)$ is shown in Fig. 2.

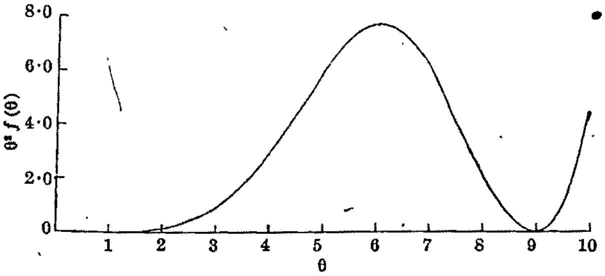

Fig. 2

It is not suggested that the idealization which has led to the results reported above is adequate to explain all the phenomena of total emission damping; but it points to a mode of attack on the problem which is hopeful. The method by which equations (1) and (2) are derived will be published elsewhere in due course.

Theory of the Streaming Potential

BOOTH[1] has recently pointed out the unsatisfactory nature of the existing theory of electrokinetics, and suggested modifications to the commonly used equations of Helmholtz[2] and Smoluchowski[3], with particular reference to the phenomenon of electrophoresis. I have devoted some attention to the theory of the streaming potential difference set up in the plane of flow when an electrical double layer, existing at an immobile interface in an ionic liquid, is sheared. This potential difference will tend to resist the flow of the liquid owing to the electrical retarding force acting on the ions of the double layer. It has been shown[4,5] that in narrow channels this electrical resistance to flow, or 'electroviscous resistance', can assume considerable importance, with the result that the apparent viscosity of a liquid in such channels may be increased several fold, depending on the values of the electrokinetic potential of the double layer, the specific conductivity of the liquid in the channel, and the dielectric constant. Various workers[6-8] have reported the qualitative observation of such an effect, and a quantitative experimental examination of the subject has been commenced in this laboratory.

In view of this apparent increase in viscosity in narrow channels, it is to be expected that zeta-potentials calculated from measurements made in diaphragms of very small particle size will lead to anomalously low results if the usual Helmholtz–Smoluchowski equation is used. The results of Bull and Gortner[9] and others[10-12] have been explained on this basis[4,5].

The results of this analysis are of importance when applied to the theories of surface conductivity and of lyophobic colloid stability, and offer an explanation of certain anomalous results obtained by workers[13-15] who attempted to measure equilibrium distances of separation between surfaces immersed in ionic liquids.

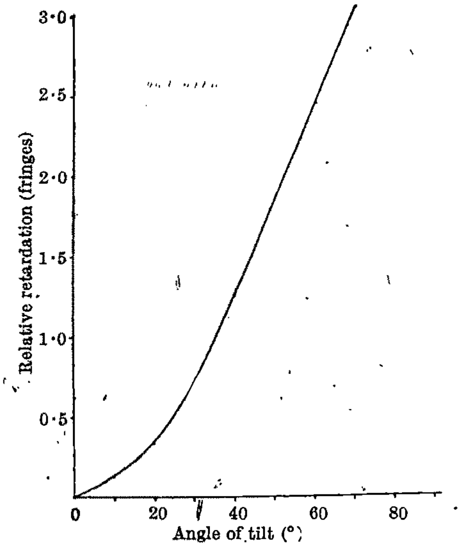
A Large Field Compensator of the Berek Type

P. E. Jellyman and A. J. Milne have described in *Nature* of March 27, p. 477, a form of photo-elastic compensator using a plate of *C.R.*39 resin in which a uniform stress variation (produced by pure bending) is frozen. A more sensitive compensator (which also depends on the frozen stress in *C.R.*39 resin) has been in use for more than a year at the Royal Aircraft Establishment. This instrument works on the same principle as the Berek compensator, in which a thin crystal slice (calcite or quartz), cut normal to the optic axis, can be tilted at various angles to the light path, giving a relative retardation increasing with the angle of tilt.

The Berek instrument is used in conjunction with a polarizing microscope. For covering fields of several inches diameter, natural crystals sufficiently large are not to be had. Instead, I have employed a plate of *C.R.*39, $\frac{3}{8}$ in. thick by about 4 in. by $2\frac{1}{2}$ in.

In the process of manufacture, the applied lateral pressure produces a frozen stress in a direction normal to the plate. This stress is not always uniform, but the piece selected had a variation of less than 3 per cent over its whole area. The *C.R.*39 sheet, which has uniform thickness, high polish and excellent light transmission, is lightly held between two frames mounted symmetrically on co-axial spindles which can rotate in a circular frame. The angle of rotation is shown by a pointer and scale. The whole frame is a sliding rotational fit in a split outer ring which is provided with an angular scale. Thus the axis of tilt can be adjusted to lie in the direction of either of the principal stresses. The inner ring is then fixed by the clamping screw. The instrument is set for compensation, and the plate is then tilted by means of a knurled knob; it can be clamped in any position. Owing to the large area of the plate it is rarely necessary to adjust the position of the instrument in the light field (except perhaps when the angle of tilt is high and the projected area is reduced).



Calibration curve for white light

One advantage of this type of instrument is that its sensitivity becomes greater for very small retardations, as is shown by the accompanying calibration curve. For a crystal slice, the slope of the curve would increase continuously. In the *C.R.*39 instrument, the slope appears to become constant. This may be due to the fact that the birefringence is not completely constant through the thickness of the material. The instrument may be calibrated directly in Angström units if desired. The calibration has stayed constant for more than a year, and is not noticeably affected by slow temperature variations in the laboratory. It is necessary, of course, to avoid stresses due to clamping.

The range of the instrument is from 0 to 3 fringes (at about 69° angle of tilt), and its sensitivity 1/20 fringe or better. The calibration can be readily checked at any time.

When used, the instrument is mounted on the photo-elastic bench between the polarizer and the model, so as to avoid displacement of the image as a result of tilting.

Isolation of a New Androstenol-3(α)-on-17 from the Urine of a Patient with Adrenal Cancer

In a previous paper (Dingemanse, Huis in 't Veld and De Laat[1]), we reported that we had detected, by means of a chromatographic-colorimetric method, a new 17-ketosteroid in the urine of patients suffering from a dysfunction of the adrenal cortex. This 17-ketosteroid, to which we refer in this paper as 17-ketosteroid II, occurs in the urine of normal individuals, as a rule, in small quantities only, and may be completely absent. Considerable amounts, however, have been found in the urine of persons with 'virilizing' tumours and with hyperplasias of the adrenal cortex.

This substance has now been isolated from the urine, and obtained in pure condition. We used for this purpose 2 litres of urine of a female child aged two, who showed symptoms of virilism, and from whom afterwards an adrenal tumour was extirpated.

The urine was neutralized and extracted according to the method of Dingemanse and Laqueur[2], and the extract was purified by means of chromatographic analysis and high-vacuum sublimation. After repeated crystallization from a watery methanol solution and from petroleum ether, a product with a melting point of 140·5–141° C. was obtained. In ethanol its specific rotation was found to be +121 ± 3°.

The quantitative analysis led to the empirical formula $C_{19}H_{28}O_2$ (H, 9·68; C, 79·06 per cent). In 80 per cent ethanol it gave no precipitate with digitonin. Titration, by the method of Rosenmund – Kuhnhenn, revealed the presence of one double bond (1·89 and 2·14 equivalents of bromine were taken up). With hydroxylamine it was found to form a monooxime with a melting point of 109–113° C. (N, 4·40 per cent). An acetate could not be isolated in the pure condition. The α-ketosteroids are, as is well known, more difficult to esterize than the β-ketosteroids.

The new ketosteroid proved to be unstable in the presence of mineral acids. When treated at room temperature with hydrochloric acid, it formed two transformation products that could be separated by chromatographic analysis. The first proved to have a melting point of 151–152° C., and the quantitative analysis led to the empirical formula $C_{19}H_{27}OCl$ (C, 74·44; H, 8·83; Cl, 11·53 per cent).

The second transformation product had a melting point of 140–141° C., and gave a precipitate with digitonin. When this substance was mixed with dehydro-*iso*-androsterone, the melting point underwent no change. Its acetate proved to have a melting point of 171–172° C.; mixing with dehydro-*iso*-androsterone acetate did not lower the melting point. We must assume, therefore, that it is identical with Δ5-androstenol-3(β)-on-17 (that is, dehydro-*iso*-androsterone).

Our idea of the reaction with hydrochloric acid is that it takes place as follows:

$$\text{17-ketosteroid II} \xrightarrow{\text{HCl}} \text{chloro-ketone} \xrightarrow{\text{HCl}} \text{dehydro-}\textit{iso}\text{-androsterone.}$$

Dehydro-*iso*-androsterone is *not* appreciably transformed in a chloroketone when it is treated at room temperature with hydrochloric acid. Butenandt[3,4] has already pointed out in a paper on the chloroketone of male urine that the precursor of this compound may be different from dehydro-*iso*-androsterone.

The configuration of 17-ketosteroid II must therefore be very similar to that of dehydro-*iso*-androsterone. For this reason it seems to us that the atom C_3 will bear an α-hydroxyl group. For a keto group at C_{17} the Zimmermann reaction is characteristic. The Pincus reaction of 17-ketosteroid II is qualitatively as well as quantitatively the same as that of dehydro-*iso*-androsterone.

On account of the fact that 17-ketosteroid II is transformed by the action of hydrochloric acid in dehydro-*iso*-androsterone, there are apparently three positions in which the double-bond might, theoretically, be present; namely, Δ4.5, Δ5.6 and Δ6.7. Ruzicka and Goldberg[5] have synthesized the Δ5.6-androstenol-3(α)-on-17, which proved to have a melting point of 221° C., and $[\alpha]_D \sim 0°$. Our new ketosteroid, therefore, cannot be identical with this substance.

As the formula Δ4.5-androstenol-3(α)-on-17 accounts better than the other ones for the instability of our substance in the presence of acids (Wolfe, Fieser and Friedgood[6]), this configuration seems to be the most plausible. Wolfe *et al.* have already pointed out that this ketosteroid might be found in urine extracts.

We have tried to ascertain the configuration of 17-ketosteroid II by oxidation, using Oppenauer's method, of the hydroxyl group attached to C_3. If the formula suggested above be correct, this ought to give Δ4.5-androstenedione. The melting point of our oxidation product proved, however, to be 185° C., and is therefore different from the melting points that have been reported for Δ4.5-androstenedione. Mixed with Δ4.5-androstenedione it showed, moreover, a sharp fall in its melting point.

The possibility that our 17-ketosteroid II might be an *i*-steroid was also considered. *I*-steroids are so far known only as synthetic products (Wallis, Fernholz and Gephart[7]). When a surplus of bromine is added, such substances ought to give tribromides (Beyon, Heilbron and Spring[8]; Wallis *et al.*[7]), whereas our product absorbed in the Rosenmund – Kuhnhenn titration but two equivalents of bromine

The investigation is being continued.

The quantitative analyses were carried out by Mr. P. Hubers in the Laboratory for Organic Chemistry of the Amsterdam Municipal University. A grant was received for this study from Organon, Ltd., Oss.

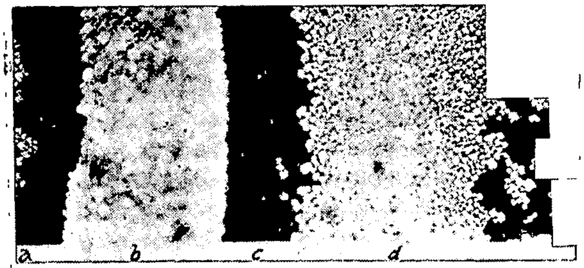
Evidence for an Electrostatic Field on Penicillin Assay Plates

ONE of the effects of penicillin on susceptible bacteria is to cause a change in electrostatic charge which may be measured in terms of ζ potentials, and which it has been suggested may be used quantitatively for assaying solutions of penicillin[1,2,3]. So early as 1938, Loiseleur[4] studied changes that occur in electrostatic charge during proteolysis, such as would be expected during lysis of bacterial cells. Similar changes in charge resulting in development of an electrostatic field can be shown on penicillin assay plates by treatment with electronegative or electropositive colloids suspended in buffers at *p*H levels above or below the isoelectric range of the nucleoproteins.

The accompanying reproduction is of a photomicrograph of a segment of an inhibition zone on a standard assay plate that was flooded for a few minutes with a suspension of starch in phosphate



SEGMENT OF AN INHIBITION ZONE SHOWING FLOCCULATION OF STARCH WITHIN ZONE buffer (pH 6·8) and from which the excess suspension was afterwards decanted. It shows (*a*) a few scattered starch grains at the site of the buffered penicillin solution inside the 'penicylinder'; (*b*) starch grains sedimented in the trough, where the 'penicylinder' had rested (out of focus because in a different plane from the surface of the agar); (*c*) a narrow ring devoid of starch around the trough; and (*d*) the circumjacent wide band of starch grains covering most of the width of the inhibition zone and extending up to the 'ring of enhanced growth' where a few scattered grains appear on the right.

Conversely, the 'ring of enhanced growth', where starch fails to flocculate, is the site of heaviest deposition of silver following flooding of the plates with an aqueous solution of silver nitrate[5,6], or of the red triphenyl formazan following treatment with solutions of triphenyl tetrazolium chloride such as have been used as indicators of seed viability[7,8].

These observations may be taken as evidence of electro-negativity in the regions of enhanced growth and of positive charges in the zones of inhibition. No such responses are seen on unseeded plates exposed to penicillin. Thus the effects cannot be attributed to reactions of the reagents with penicillin diffusing from the cylinders.

The pH effect postulated by Carr[9] to account for the mechanism of the Feulgen reaction may be demonstrated by comparing plates stained with basic fuchsin at pH values above 6·2 or below 4·8. The more acid solutions stain the colonies in the background intensely red, thus sharply outlining the unstained inhibition zones, from which the desoxyribose nucleic compounds have been dispersed. There is relatively poor definition of the zones on plates stained with the less acid solutions.

Grateful acknowledgment is made to the Cutter Laboratories, Berkeley, California, for partial support of these experiments.

Fœtal Hæmoglobin and Erythroblastosis

THE hæmoglobin of the fœtus and the new-born child and the hæmoglobin of older children and adult people can be distinguished by their different resistance against 0·1 N sodium hydroxide. At pH 12 normal hæmoglobin is denatured very rapidly, whereas fœtal hæmoglobin is denatured only slowly. By using this difference in denaturating-rate, it is possible to calculate the amounts of fœtal and later hæmoglobin present in small samples of blood[1]. A normal new-born child has only fœtal hæmoglobin. During the early months after birth, this hæmoglobin is gradually replaced by later hæmoglobin, at a rate of a little less than 1 per cent a day, so that after 120 days normally all fœtal hæmoglobin has disappeared. In prematurely born babies, later hæmoglobin appears only at the time that the child ought to have been born[2].

In new-born children suffering from erythroblastosis fœtalis caused by the *Rh* antagonism there is a marked difference in behaviour of the two hæmoglobins. The fœtal hæmoglobin is broken down very rapidly, so that in severe cases it has practically disappeared from the blood within about five days. In less severe cases the breakdown stops after about six days and a certain amount of the fœtal hæmoglobin remains. This remaining fœtal hæmoglobin disappears during succeeding months as it does in normal children. On the other hand, later hæmoglobin normally not found in the blood shortly after birth is already present in these patients at the moment of delivery. It is present in an amount up to 4 gm. per 100 c.c. of blood. This later hæmoglobin is not broken down, or only very slowly, during the serious hæmolysis, the fœtal hæmoglobin being broken down rapidly. When the child survives, its amount rises slowly later on. The *Rh* antibodies which are the cause of the destruction of the red blood corpuscles and of the hæmoglobin have not the same action on the cells containing fœtal and later hæmoglobin respectively. Only those which contain fœtal hæmoglobin are hæmolysed.

The presence in the blood at the moment of birth of later hæmoglobin, which is not broken down in children suffering from erythroblastosis, must be the result of a reaction of the child before birth against the *Rh* antibodies of the mother.

Action of Sulphuryl Chloride on Wool

ONE of several general methods of making wool unshrinkable depends for its success on disulphide-bond breakdown in the surface of the fibres. A solution of sulphuryl chloride in white spirit is sometimes used for this purpose[1]; but it has now been found that treatment which is effective with commercial fabric is relatively ineffective when the latter is freed from adsorbed soap and residual oil by extraction with alcohol and ether.

Samples of extracted and unextracted flannel (2·5 gm.) were conditioned at 65 per cent relative humidity and 22·2° C. before being immersed in 100 c.c. of a 2·5 per cent (v./v.) solution of sulphuryl chloride in carbon tetrachloride for one hour at room temperature. After treatment, the samples were neutralized with sodium bicarbonate solution, washed in running water, and then milled by hand for fifteen minutes in 5 per cent soap solution. The resulting shrinkages are given in Table 1, which includes data for an extracted sample to which 0·5 per cent by weight of oleic acid (I.V. 83·7) had been added before treatment with sulphuryl chloride.

TABLE 1

Fabric	Treatment	Percentage shrinkage in area
Extracted	None	42·7
Unextracted	Sulphuryl chloride	3·2
Extracted	,, ,,	25·0
Extracted + oleic acid	,, ,,	−7·3

Similar results were obtained with white spirit as the solvent, and the effect of oleic acid in promoting the reaction between wool and sulphuryl chloride is remarkable. When, however, oleic acid is added to the solution of sulphuryl chloride in carbon tetrachloride, instead of to the wool, no beneficial effect is obtained, as is shown by the data of Table 2.

TABLE 2

Fabric	Treatment	Percentage shrinkage in area
Extracted	None	43·7
Extracted	Sulphuryl chloride	24·0
Extracted + oleic acid*	,, ,,	–5·0
Extracted	Oleic acid* + sulphuryl chloride	24·6

* 1 per cent on the weight of the wool.

Further, the action of oleic acid in assisting the reaction is not entirely lost when the fabric to which 1 per cent of oleic acid has been added is left in carbon tetrachloride for periods up to two hours, or is washed in three changes of carbon tetrachloride over a period of one hour, before adding sulphuryl chloride.

The most probable explanation of these results is one based on the work of Kharasch and Brown[2]. If peroxides in the oleic acid are adsorbed by the wool, they will promote the formation of free chlorine atoms at the wool-solution interface :

$$R\cdot + SO_2Cl_2 \rightarrow RCl + SO_2 + Cl\cdot.$$

The chlorine atom may then react with the disulphide bond of wool :

$$R{-}S{-}S{-}R + Cl\cdot \rightarrow R{-}SCl + R{-}S\cdot.$$

$$R{-}S\cdot + SO_2Cl_2 \rightarrow R{-}SCl + SO_2 + \cdot Cl,$$

and so on, thus causing unshrinkability. When, however, oleic acid is dissolved in carbon tetrachloride, instead of being applied to the wool, free chlorine atoms are more easily lost by reaction with the oleic acid itself. In support of this explanation, it should be added that stearic acid (I.V. 5·2) has little catalytic effect on the reaction between sulphuryl chloride and wool.

Demonstration and Separation of Noradrenaline, Adrenaline and Methyladrenaline

A SIMPLE and reliable means of recognizing noradrenaline, adrenaline and methyladrenaline, singly or in mixtures, has been obtained by combining two methods : one enzymatic and the other chromatographic.

Enzymatic. An insoluble polyphenolase is prepared from shoots or roots of *Atropa belladonna* by blending twice with acetone and discarding the fluid. The solid residue is extracted three times with water, and further washings should give no colour reaction with ninhydrin. The residue is dried at room temperature and ground to a 60-mesh powder. It can be stored in a stoppered bottle without loss of activity for several months. Dried belladonna leaf is obtainable from manufacturing chemists, and, if retaining a green colour, contains active enzyme.

For the test, a few drops of solution containing not less than about 20 μgm. of the adrenaline are diluted in a test-tube with 2 ml. phosphate buffer, *p*H 7·8. About 50 mgm. enzyme (the exact amount is immaterial) is added and shaken into a suspension. The tube is kept at 30° C. for ten minutes and the colour is then observed. If adrenaline was present it will be bright orange-red (adrenochrome) and, if noradrenaline was present, pale brown. The adrenochrome is stable in solution for several hours and then slowly fades. The brown coloration is due to condensation products of noradrenochrome which are precipitated in a dark layer at the bottom of the tube. Under the conditions described, the bright red colour of noradrenochrome is never visible, and no confusion can occur. If inorganic oxidizers are used, this colour appears strongly at first and no easy distinction from adrenachrome is possible. Methyladrenaline gives no colour reaction.

The reactions of several related polyphenols have been observed ; the primary amines tend to resemble noradrenaline and the secondary amines resemble adrenaline. Thus, 3,4-dihydroxytyramine gives no detectable red stage; 'Dopa' gives a transient pink stage which passes rapidly to brown and then to a black precipitate easily distinguished from the noradrenaline brown. Corbasil gives a temporary red colour which passes over to brown ; it is distinguished from noradrenaline by the red phase and from adrenaline by the brown. Among the secondary amines, epinine and N-methylcorbasil give a red that is much less stable than adrenochrome and fades within the hour. There is no difficulty after one trial with known solutions in distinguishing any of these changes from those due to noradrenaline and adrenaline. In a mixture of noradrenaline and adrenaline, a pale brown colour develops first and is followed by a stable red colour, a sequence that is not obtained with any one substance.

Chromatographic. A good separation of the adrenalines is obtained on a Whatman No. 1 paper chromatogram, using the one-way method of Consden, Gordon and Martin[1] with phenol as solvent. The amines are applied as hydrochlorides from neutral or slightly acid solution. In this state they are stable in air and not destroyed by heating to about 100° C. when driving off the phenol. Potassium ferricyanide, made up to 0·44 per cent in phosphate buffer *p*H 7·8, is used as indicator. Oxidation of the adrenalines is immediate and leads to a brownish-red spot with noradrenaline and a bright red spot with adrenaline. Methyladrenaline does not give a colour when oxidized, since no indole ring-closure is possible ; but the ferricyanide is bleached by reduction so that a white spot is left on the paper that does not turn yellow until a considerable excess of ferricyanide is applied. As soon as the white spot is defined, the presence of methyladrenaline may be confirmed by adding one drop of very dilute copper sulphate. A red colour (due to ferrocyanide) is given, whereas the surrounding ferricyanide, in the absence of a reducer, gives a brown. The highly sensitive arsenophosphotungstate blue, sometimes used for detecting the adrenalines, is not suitable as an indicator, since it is produced by reduction of the reagent on the surface of the paper itself. Ninhydrin gives a strong coloration with noradrenaline, but a very weak one with adrenaline. It sometimes affords useful confirmation for the former if interfering amino-acids are not present.

So far, no second solvent has been found in addition to phenol that will separate the adrenalines. Very little movement occurred in *n*-butanol and none in collidine, amylacetate or butyric acid. All runs have been for approximately twenty hours at room temperature, and the R_F values observed were as follows:

Noradrenaline	$(HO)_2\ \varphi\ CHOH.CH_2.NH_2$	0·216
'Dopa'	$(HO)_2\ \varphi\ CH_2.CH.COOH.NH_2$	0·230
3,4-Dihydroxytyramine	$(HO)_2\ \varphi\ CH_2.CH_2.NH_2$	0·320
Corbasil	$(HO)_2\ \varphi\ CHOH.CH.Me.NH_2$	0·408
Adrenaline	$(HO)_2\ \varphi\ CHOH.CH_2NH.Me$	0·441
N-methylcorbasil	$(HO)_2\ \varphi\ CHOH.CH.Me.NH.Me$	0·706
Epinine	$(HO)_2\ \varphi\ CH_2.CH_2.NH.Me$	0·760
Methyladrenaline	$(HO)_2\ \varphi\ CHOH.CH_2.NMe_2$	0·796

It will be seen that the movement of these substances in phenol is determined mainly by the terminal amine group and that the R_F increases as this is methylated. An ideal separation is consequently achieved between the three adrenalines. Taking the list as a whole, satisfactory separation in a mixture cannot be guaranteed if the difference of R_F values falls much below 0·1. The confusion most likely to matter in tissue extracts is that between noradrenaline and 'Dopa'. This is easily resolved by the enzyme test, because of the black colour given by 'Dopa'. Adrenaline can be distinguished from corbasil with a similar R_F by the much greater stability of adrenochrome over the corresponding corbasil derivative in the enzyme tests.

These methods have been successfully applied to the demonstration of noradrenaline and adrenaline in tissue extracts. I am indebted to Dr. H. Blaschko for samples of most of the compounds used.

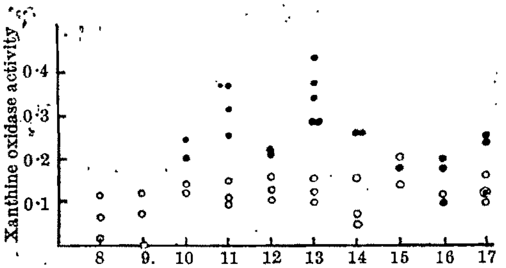
Association of Xanthine Oxidase with Virus Multiplication

It has previously been reported that the xanthine oxidase content of mouse brain is markedly increased during infection with yellow fever and other viruses[1,2], and evidence was adduced which suggested that this rise of enzyme activity was not fortuitous but was causally related to the growth of virus in the tissue. The possibility of the virus particles themselves having xanthine oxidase activity was excluded by the demonstrable lack of parallelism between enzyme activity and the amount of virus in the brain. Recent work reported here shows that the extra enzyme is not obtained from other parts of the body, and demonstrates that synthesis of xanthine oxidase takes place during virus infection.



○, NORMAL EMBRYOS; ●, EMBRYOS INFECTED WITH 17 *D* STRAIN OF YELLOW FEVER VIRUS

Fertile eggs at the ninth day of incubation were inoculated with the 17 *D* strain of yellow fever virus by the allantoic route, and were then incubated for a further period. In a preliminary survey of the enzyme activity of the various tissues of both normal and virus-infected eggs, it was found that xanthine oxidase was present only in the chorioallantois and the embryo. In all subsequent experiments the embryo and membrane were ground up together with twice the weight of water and centrifuged, and the supernatant fluid was tested for xanthine oxidase activity by the Thunberg technique. The enzyme activity of the combined tissue extract was expressed in arbitrary figures per unit weight of tissue. The results are shown in the accompanying graph. The values for normal embryos remain fairly constant throughout the period of incubation investigated; since the weight of the embryo increases from 1 to 20 gm. over this period, a continual synthesis of xanthine oxidase must be taking place of sufficient extent to maintain a uniform value per unit weight of tissue. The values for embryos infected with virus are in nearly all cases considerably higher than normal, the increase being particularly noticeable on the thirteenth day; between the thirteenth and eighteenth days the activity falls towards the normal level. Since these determinations were all made upon the embryo plus the chorioallantoic membrane, which together represent the only available source of xanthine oxidase, it is evident that the enzyme content of the whole egg is increased in response to the virus infection, and that the possibility of enzyme accumulating in infected tissues from depots elsewhere can be excluded. In addition to the synthesis of xanthine oxidase which is taking place in the normal embryo, there is thus an additional synthesis brought about by the presence of the virus, and it is suggested that this extra amount of enzyme is required for virus metabolism.

There are certain points to be noted in comparing these results with those already reported for mouse encephalitis. (1) In the chick embryo there is very little cellular response to the presence of the virus, so that the rise of enzyme activity is not likely to be due to the presence of a round-cell infiltration. (2) The maximum enzyme activity (0·44) is lower than that found in mouse brain (1·6), which may be related to the lower virus titre (10^5 in the embryo and 10^7 in the mouse brain). (3) The virus titre and enzyme activity both fall from the thirteenth day onwards, and a similar fall of enzyme activity is seen in mouse encephalitis after the onset of symptoms and attainment of maximum virus titre; these facts suggest that enzyme synthesis is connected with the active proliferation of virus and occurs only during this phase.

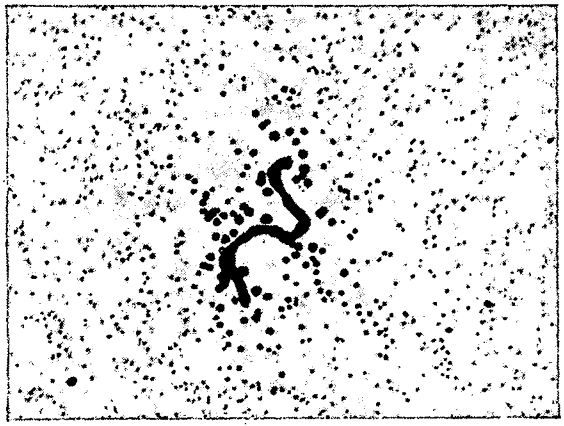
Unsaturated Fatty Acids in Cotton Wool Plugs

During a study of a diphtheroid bacterium (not yet identified, but temporarily labelled *Q*) it has been found that the slight growth on nutrient agar can be abolished by adding 0·2 per cent charcoal to the agar. Growth on charcoal-agar could be restored by adding excess of oleic, linoleic or linolenic acids. Experiments in synthetic media showed that the organism requires these unsaturated fatty acids as growth factors.

It was noted that 'satellitism' of colonies of *Q* occurred on charcoal-agar plates around a fibre of cotton wool accidentally dropped on the surface (see accompanying illustration). It appeared that the cotton fibre was supplying the necessary fatty acid growth-factor. 20 gm. of the ordinary non-absorbent cotton wool used in the laboratory for plugging all sterile glassware were therefore extracted for 3 hr. in a soxhlet with methanol, yielding 24·7 mgm. (more than 0·12 per cent) of petrol-soluble lipoid.



GROWTH STIMULATION, BY A COTTON FIBRE, OF MICRO-COLONIES OF A BACTERIUM (Q) REQUIRING OLEIC ACID; MEDIUM NUTRIENT AGAR CONTAINING 0·2 PER CENT CHARCOAL. × 25

This phenomenon was at once linked with the observation that a greasy film developed on the inside of flasks and tubes, previously acid-cleaned, plugged with cotton wool and sterilized by treatment for 1½ hr. in the oven at 180°. This greasy film, which was itself invisible, was only detected because it rendered the surface of the glass completely hydrophobic. It did not appear when plugs made of the extracted cotton wool were used. The bacteriostatic properties of the fatty distillate from cotton wool plugs has previously been reported by Wright[1] for pneumococci and by Drea[2] for tubercle bacilli, but the importance of their observations has not perhaps been fully appreciated.

When the fat-extracted cotton wool was used for plugging flasks in experiments with *Q*, the organism completely failed to grow in the absence of oleate; whereas previously, with ordinary plugs, quite considerable, though variable, growth had occurred in the basal synthetic medium alone.

It was thus possible, using *Q* as the test organism, to make a rough assay of the growth-promoting activity of the fatty extract from cotton wool, which was found to be 25–50 per cent that of oleic acid. (It should be mentioned here that pure linoleic and linolenic acids have exactly the same growth-promoting activity for *Q* as oleic acid, while the two saturated acids, palmitic and stearic, are quite inactive.) It was calculated that each cotton wool plug contained 0·5–1·0 mgm. of oleate-equivalent lipoid. Further, by measuring the average growth of *Q* in 5 ml. of basal medium without oleate in 50 ml. flasks plugged with ordinary cotton wool and sterilized in the usual way by hot air at 180° for 1½ hr., the oleate-equivalent quantity of lipoid distilled off the plugs and afterwards dissolved in the medium amounted to about 10 μgm. per flask. The same figure was arrived at by assaying the activity of petroleum-ether washings from samples of dry flasks, similarly plugged and sterilized. This amount was quite enough to give considerable growth of *Q*, which responds visibly to a concentration of 0·5 μgm. oleic acid per ml., and also to cause marked inhibition of organisms, such as *H. pertussis*, which are highly sensitive to unsaturated fatty acids. A strain of *H. pertussis* was found to grow heavily in broth with 0·01 per cent albumen in flasks with extracted cotton wool plugs, but failed completely to grow in the same medium in flasks with ordinary plugs.

Long-chain unsaturated fatty acids such as oleic, linoleic or linolenic (which may be derived from cotton wool in its natural state or after washing with soap solutions) have remarkable activity both as growth-promoters[3-7] and growth-inhibitors[2,3,8,9] of a wide variety of micro-organisms, down to a concentration of 1 μgm./ml. or less. These substances may thus be responsible for erratic results in growth experiments on sensitive micro-organisms where cotton wool is used for plugging tubes afterwards sterilized in an oven at high temperatures. To avoid this difficulty, Wright[1] suggested using a particular grade of absorbent cotton wool, and sterilizing by autoclave followed by drying at 120°. The fatty acid content of absorbent cotton wool, however, depends largely upon its method of preparation and may be higher than that of the non-absorbent variety. It is clearly preferable to attempt to get rid of the easily liberated fat by extraction with an organic solvent such as methanol (as described) or, even better, to use some substitute such as glass, 'Cellophane' or aluminium caps as recommended by Drea[2]. A more promising substitute which is being tested here at the moment is a very fine glass wool (Fibreglass, Ltd.). This is unfortunately treated with a mixture containing oleic acid in the process of manufacture, but can easily be subjected to fat-extraction and/or treated with concentrated acid and so obtained as chemically clean as the flasks themselves.

Regulation of Oviposition in Social Hymenoptera

The rate of increase of population in societies of social insects obviously depends upon the numbers of adults which can be produced per head of the adult population. Ideally, the numbers of eggs laid should be just appropriate to this situation, so that the prevailing food supply may be efficiently transformed.

In a study of *Bombus agrorum* Fab. kept in observation nests with free access to the open, and not fed in any way, it has been noticed that eggs excepting the first were only laid on pupal cells, and by far the majority on cells up to three days after formation.

NUMBERS OF EGGS LAID ON PUPAL CELLS 1, 2, 3, . . ., ETC., DAYS AFTER FORMATION IN A COLONY OF *B. agrorum* ssp. *septenzionalis* VOGT.

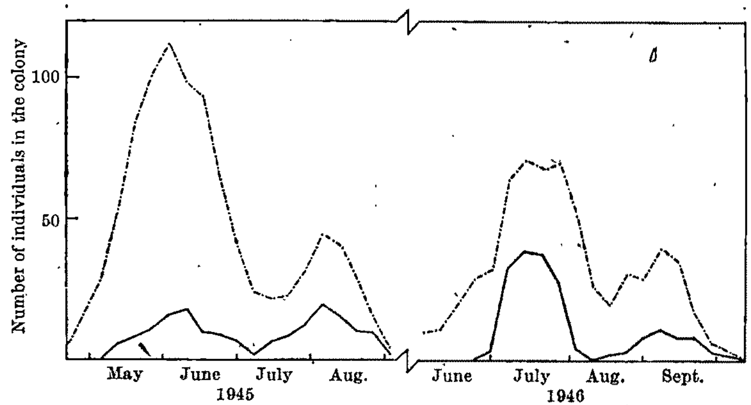
Age of pupal cell (days)	1	2	3	4	5	6	7	8	9	10	11	12
Numbers of eggs laid	18	50	38	18	15	9	7	0	0	8	0	0

This association of eggs with metamorphosis may have been the result of a reduced 'demand' on the part of larvæ for attention—more particularly, food; but that a direct response to the presence of pupæ was involved is perhaps suggested by the fact that the numbers of eggs laid (X) was proportional to the size of the pupal mass, that is, to the numbers of pupæ in each batch (Y). The equation relating these was

$$X = 2{\cdot}84\,Y + 0{\cdot}16$$

(standard error of regression coefficient, 0·53 eggs per pupa), which means that about three eggs were laid per pupa. By thus replacing each fully grown and metamorphosed larva with three eggs, a reasonably continuous regulation of larval numbers was achieved, as the eggs took only six days to hatch. Since several groups of brood ran concurrently, but out of phase, all ontogenetic classes were present in the nest at any time, and it seems likely that in the bumble-bee a fairly sensitive method of regulating the time of appearance and quantity of brood to the capacity of workers to tend it has been evolved.

In colonies of the ants *Myrmica lævinodis* Nyl. and *M. ruginodis* Nyl. kept in observation nests under normal climatic conditions, as well as at constant temperatures, and subjected to weekly censuses, a marked temporal association of eggs and pupæ has also been observed (see graph); and it has been noticed that oviposition tended to increase soon after metamorphosis had started. The result, in spite of the fact that the over-wintering larvæ—all in third instar—ranged in weight from 0·24 mgm. to 3·10 mgm., was not an immediate replacement, and a consequent approximately constant larval population; since the eggs took more than a month to hatch. In fact, over-wintering larvæ had usually all metamorphosed before many new larvæ appeared. Moreover, since the period of oviposition was approximately equal to the period of metamorphosis, the appearance of young larvæ coincided with the amplification of the worker force. Thus, instead of a continuous replacement of larvæ and a steady flow of material through the ontogenetic classes, there was in these species of ant, in contrast to the bumble-bee, a phasic alternation of egg and pupal increase with larval and worker increase. Two such maxima, the first larger than the second, have occurred each year in *M. lævinodis*. But although a regulation of the time of oviposition has been observed, there has been no indication so far of a quantitative relation between the numbers of pupæ formed and the number of eggs laid as in *Bombus*.



FLUCTUATIONS IN NUMBERS OF EGGS AND PUPÆ IN A COLONY OF *Myrmica lævinodis*, 1945 AND 1946

—.—.—., eggs ———, pupæ

A clear understanding of the factors involved in this situation cannot be obtained until much more is known about the mode of organisation of activities in these colonies, of the times and energies necessary for performing the various actions, and of the complex effect of variations in ontogenetic class composition which a never static worker force has to cope with. If larvæ receive prime attention, then it is plausible to suggest that egg-laying is proportional to the spare worker-power up to a point where the queen's constitution becomes the limiting factor. But it is equally plausible to suggest that in ants, as in bumble-bees, the queen responds directly to the arrival of pupæ, an action which is facilitated by the increasing attention the workers can give her. It is not inconceivable that some hormone affecting both processes—egg formation and metamorphosis—may be transmitted or absorbed through the medium of the 'social stomach'.

Ciliate Protozoan Fauna of Soil and Inland Waters

A YEAR's study of the bacteria in the current core of a chalk stream has shown that there is a natural water bacterial flora (*Pseudomonas* sp., *Flavobacteria*, *Micrococci* sp.), which was supplanted by a bacterial flora of soil types (*Bs. mycoides*, *Bs. subtilis*, *Actinomyces* sp., *Bt. coli* irregulars) after heavy rain, floods or prolonged periods of hot dry weather when presumably a continuous rain of earth crumbled into the stream.

It was also observed that bacteria-eating ciliates in the current core were most numerous and most varied when a soil bacterial flora predominated. Further, many of these bacteria-eating ciliates (for example, *Colpoda*, *Halteria*, *Holophyra*) appeared in numbers after heavy rain, floods or periods of hot dry weather, that is, after the same physical conditions which had ushered a soil bacterial flora into the stream.

It was assumed that soil ciliate protozoa might have been washed into the stream, and examination of the soil on its banks, and of the soil 200 yards away on the banks of gullies emptying into the stream, showed the presence of ciliates many of which were indistinguishable from forms found in the stream (*Colpoda, Holophyra, Oxytricha, Halteria*). Ciliate protozoa indistinguishable from forms found in the stream were also obtained from within dried mud originally excavated from the bottom of the stream and cast on adjoining fields (*Oxytricha, Halteria*).

Singh[1] observes that "the satisfactory edible bacteria in estimating protozoal numbers [in the soil] belong to strains of small cocci or non-sporing rods". Following this suggestion, it was found that soil ciliate protozoa from the above situations developed only slowly in artificial culture—in one to two weeks—if the sole food supply was the natural soil bacteria. If, however, the culture was inoculated with micrococci isolated from the stream, a massive development occurred within three to five days.

From these observations it is suggested that there is a free exchange between soil ciliate protozoa and those of inland waters, and that any distinction drawn between them is apparent and not real; in short, that water ciliates are identical with those of the soil, one habitat being the source of the other.

Separation of Polar from Non-Polar Molecules

AFTER an interruption due to the War, I have re-commenced experiments aiming at the separation of molecules having a permanent dipole moment from non-polar molecules in liquid mixtures by the aid of a non-uniform electric field.

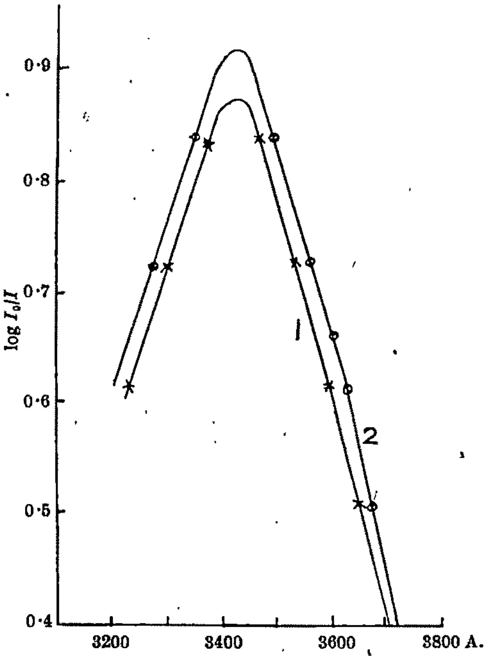
The ratio of the polar and non-polar molecules (N_p/N_n) will undergo a change to the value $(N_p/N_n)_r$ at a point r with the electric field strength E_r given by the expression:

$$\left(\frac{N_p}{N_n}\right)_r = \left(\frac{N_p}{N_n}\right)_0 \exp\frac{\mu E_r \cos\theta + \frac{1}{2} E_r^2 (\alpha_p - \alpha_n)}{kT},$$

where μ is the permanent dipole moment, E_r the intensity of the electric field at the point concerned, $\cos\theta$ the mean cosine of the orientation angle, α_p and α_n the polarizabilities of the polar and non-polar molecules respectively, and k the Boltzmann constant.

In evaluating this formula, which does not take into account a possible interaction between polar and non-polar molecules, the complete Langevin function for the calculation of the values of $\cos\theta$ has been used. Plotting the ratio $(N_p/N_n)_r$ against the logarithm of the field intensity and making $(N_p/N_n)_0 = 1$ shows that up to 10^5 volt./cm. no appreciable deviation from the value 1 is to be expected. But from that value on a very rapid increase occurs, reaching several per cent at 10^6 volt./cm. At still higher fields, which of course cannot be reached due to the sparking potential, the ratio would increase rapidly to very great values.

In the apparatus used the liquid mixture is placed in a radial field produced in a metallic cylinder of 2 cm. diameter coaxial with a thin tungsten wire of 0·020 mm. diameter, which passes through a glass capillary of 0·1 mm. diameter. The tungsten wire protrudes 1–2 mm. beyond the end of the capillary. On applying potentials up to 10,000 volts, which are below the sparking potential of the cell, an electric field of the magnitude of 10^6 volts./cm. is established close to the thin wire. The liquid around it up to a distance of 0·1 mm. is continuously collected at a very slow rate and its refractive index is compared with that of the original solution by means of a liquid-interferometer.



Using benzene–nitrobenzene mixtures, and plotting the observed interferometric deviation against the potential applied, it is found that an enrichment of nitrobenzene up to 0·7 per cent takes place in the solution for 6,000 volts applied. With *p*-nitroaniline solution in benzene and potentials up to 10,000 volts, a change of the concentration up to 12 per cent has been observed. The accompanying graph shows the ultra-violet absorption of the *p*-nitroaniline solution collected from the vicinity of the tungsten wire (Curve 2) and the absorption curve of the original solution (Curve 1). The position of the maximum is not altered, but the extinction is increased, showing an enrichment of the solution for the polar molecules of *p*-nitroaniline.

In a second apparatus the mixture was allowed to pass through a metallic net, with the horizontal wires forming the negative pole and the vertical ones the positive. They were insulated from each other so that potentials of up to 1,000 volts could be safely used. The net was wound about a glass rod and then placed in a glass tube. The dimensions were such that there were 42,000 intersection points, forming the non-uniform field, in a volume of 100 ml. After passing through the net, the liquid proves to be poorer in polar molecules compared with the liquid remaining in the tube. This shows that the net acted as a dipole filter.

At present work is in progress to amplify the changes in concentration by application of the method of counter-streams. A fuller report of this work is being prepared.

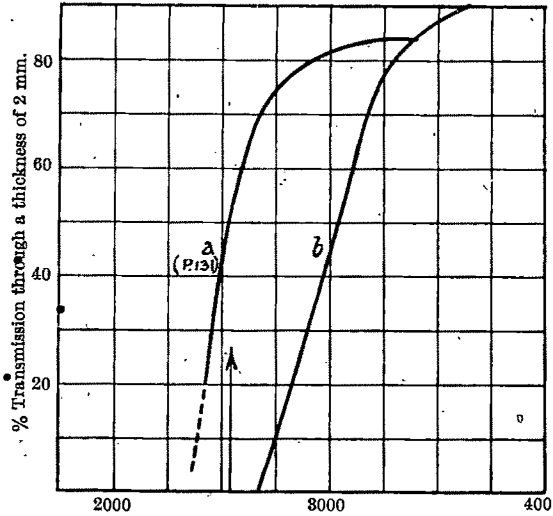
Transmission of Bactericidal Radiation through Glass

It is well known that iron, present in glasses as an impurity, has a most important effect in reducing their transmission of ultra-violet radiation. Of both theoretical and practical importance is the exact quantitative effect, at various wave-lengths, of iron in both the ferrous and ferric condition and in glasses of various compositions. On this question the most authoritative work known to me is that of D. Starkie and W. E. S. Turner[1] who, unlike other authors, quoted precise chemical compositions, including ferrous and ferric iron contents, together with complete transmission data. Curve *P*.131 in the graph is taken from their work and shows that a soft soda glass containing 0·01 per cent of iron oxide cut off completely at ~ 2650 A., the iron in the glass being practically all in the ferrous condition. With the same percentage iron content, but practically all in the ferric condition, the same glass cut off at even longer wave-lengths (~ 2675 A.). Starkie and Turner studied a glass containing so little as 0·005 per cent iron oxide, and concluded by extrapolation that a glass completely without iron would cut off at ~ 2230 A.



PERCENTAGE TRANSMISSION CURVES FOR (*a*) *P*.131 GLASS CONTAINING 0·010 PER CENT IRON OXIDE; (*b*) ONE OF THE NEW GLASSES CONTAINING 0·010 PER CENT IRON OXIDE, THE CURVE IN THE LATTER CASE *not* BEING CORRECTED FOR REFLEXION LOSSES. THE VERTICAL ARROW INDICATES THE 2537 A. LINE

Small melts made in this Laboratory during 1939, using platinum–rhodium crucibles and pure materials, showed that it was possible to make a silicate glass containing about 15 per cent of alkali oxides and having a transmission at 2537 A. of ~ 70 per cent for a thickness of 1 mm. This work was interrupted by the War; but the subject is now under investigation again.

In large-scale melting it is very difficult to keep the iron oxide very much below 0·01 per cent, and an important question, therefore, is the possibility of obtaining good transmission at 2537 A. with about this percentage of iron oxide. We have established that a soft soda glass of linear expansion coefficient ~ 9·5 × 10^{-6} per ° C., and containing 0·01 per cent of iron oxide, may have the transmission curve shown in the graph, when made on a scale of several hundredweights at a time.

Two main conclusions may be drawn from the work, as follows:

(*a*) Soft glasses, even when containing as much as 0·01 per cent iron oxide, may be made with remarkably good ultra-violet transmission at 2537 A., and much remains to be done before one can say precisely where the absorption edges occur for glasses completely free from iron. It may be remarked in this connexion that even the new glass referred to is distinctly coloured when viewed in thicknesses of a few inches. It follows that one cannot yet estimate exactly the specific effect the main constituent oxides of glasses have on the position of the absorption bands, and this should be remembered when studying the work of previous experimenters.

(*b*) Hitherto, in the manufacture of bactericidal lamps, it has been assumed that hard borosilicate glasses must be used. The above work shows that glasses of expansion coefficient ~ 9·5 × 10^{-6} may have good transmission at 2537 A., and this has the practical advantage that seals may be made to relatively easily available alloys and soft glasses.

The whole subject is under active investigation in this Laboratory, and it is hoped to publish detailed results at a later date. I would thank Mr. L. J. Davies, director of research, for permission to publish this communication.

Stimulation of Growth in Pigs by Iodinated Casein and Stilbœstrol

THE earlier attempts to stimulate the growth-rate of pigs by administration of thyroid-active substances[1] and of synthetic œstrogens[2] have been followed by tests in which both treatments were given simultaneously.

	Average initial weight	Average final weight after 19 weeks	Average gain	Average amount of food required for 1 lb. live-weight gain
Trial 1				
Control animals (6)	41·0	201·5	160·5	3·79
Treated animals (6)	41·8	219·3	177·5	3·63
Trial 2				
Control animals (6)	43·5	218·8	175·3	3·76
Treated animals (6)	42·7	235·0	192·3	3·44
Both trials combined				
Control animals (12)	42·3	210·2	167·9	3·78
Treated animals (12)	42·3	227·2	184·9	3·54

Young growing castrated male pigs, ten to twelve weeks old at the beginning of the trials, received daily additions of iodinated casein and stilbœstrol to the food throughout the fattening period. The results for the first twelve pairs are now available. The treated pigs showed a substantially greater rate of growth than their control litter-mates, and more efficient food utilization. No untoward effects due to treatment have been observed. The accompanying table gives the relevant information. Further tests are in progress to confirm these preliminary findings and will be reported later.

The help of Miss E. Henriques is gratefully acknowledged.

A Radioactive Local Anæsthetic

THE method of production of the local anæsthetic, dibromo procaine, described below, is of wide application, permitting the rapid formation of a saturated solution of radioactive hydrobromic acid from a small mass of active bromide. The hydrobromic acid serves as a basis for many brominations.

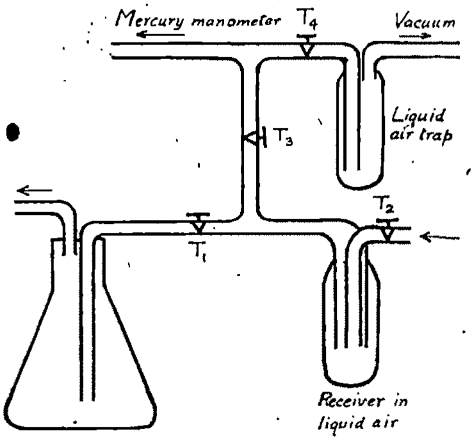
A solution of active bromide is converted to silver bromide by addition of excess silver nitrate. The precipitated silver bromide is dried, and reduced in a silica tube furnace at 800° C. by a stream of dry hydrogen. The furnace outflow, consisting of hydrogen and hydrobromic acid gas, is led through a receiver standing in liquid air and containing the calculated volume of distilled water. A manometer at the hydrogen inlet gives warning by showing a rise of pressure should the receiver become 'iced up'; this should not occur if the bore of the receiver tube is adequate for the mass of silver bromide to be reduced.

The hydrogen escaping from the receiver is led through a solution of silver nitrate (left of diagram), thence out to the air. Clouding of this solution indicates that hydrobromic acid is being carried through, and the rate of hydrogen flow is appropriately adjusted. Forty-five minutes is more than adequate for total reduction of 0·5 gm. silver bromide.

The furnace is disconnected, taps T_1 and T_2 closed, T_3 and T_4 opened and the receiver exhausted with a suitable pump. Tap T_4 is now closed and the receiver, connected only with the manometer in the vacuum circuit, is removed from the liquid air and its base slowly immersed in water at room temperature; the ice melts before the hydrobromic acid higher in the trap. The acid then resumes the gaseous state and dissolves in the water. Should the manometer show a significant rise of pressure above atmospheric, it is only necessary to re-immerse the flask in liquid air for a moment and recommence. In about five minutes, the fuming radioactive hydrobromic acid is ready for use.

Bromination is achieved according to the method of Morel and Leulier[1], who, in 1929, produced a dibromo procaine and investigated it pharmacologically and chemically, ascribing to it the formula $C_{13}H_{18}Br_2N_2O_2HBr$.

The calculated quantity of procaine is added to the hydrobromic acid in the receiver and about 0·5 c.c. of 100-volume hydrogen peroxide introduced. There is a brisk reaction and rapid precipitation of dibromo procaine. If the reaction becomes too violent, further peroxide is added to slow it down. The time taken for this reaction may vary from minutes to hours, depending on the concentration of reagents and, since the half-life of Br^{82} is only 34 hours, the need for a concentrated acid is obvious. In my series of experiments, the dibromo procaine was recrystallized. The conversion of potassium bromide to dibromo procaine can be completed comfortably in one and a half hours. An account of my radio-autographic studies will be given later.



Discussion. The method described has advantages over the simpler techniques for bromide-acid conversion. It is almost quantitative and commends itself when a bromide of small mass and low activity is to be dealt with. It involves no intermediate stages with loss of active substance. Radioactive bromine is usually provided as a simple bromide, so the method has a wide field of application; it is also satisfactory with highly active bromide, in that the system is a closed one and in no stage is a radioactive gas, with its attendant hazards, liberated in the laboratory.

Morel *et al.* have produced several brominated natural alkaloids, and have studied their properties, thus paving the way for experiments with the active bromine isotope.

As yet the synthesis of a complex molecule incorporating one or more radioactive C^{14} atoms presents considerable difficulty and involves losses of C^{14}, in spite of the most careful technique, while many compounds of great pharmacological interest cannot yet be synthesized; it is to bridge this gap that some simple method of labelling is required, and a halogen seems to be the 'label' of greatest general utility at present.

I wish to thank the staff of the Liverpool and Cambridge cyclotrons, and also Prof. A. D. Macdonald, for facilities in his laboratory.

"Plant Geography"

BOOK reviews are of value not only to readers but also to writers, and I am therefore sorry that Sir Edward Salisbury did not, in his notice of my book "The Geography of the Flowering Plants" in *Nature* of May 8, give us his views on any of the more profound modern problems of phytogeography with which it tries to deal.

With regard to the point which he particularly stresses, namely, the question of the value of specialized dispersal mechanisms, I remain unrepentant and see no reason to modify my belief that a broad acquaintance with the Angiosperms and their distribution allows of no other conclusion than that which the reviewer criticizes.

It is also only proper to point out that the incomplete sentence which Sir Edward quotes from my book in the second paragraph of his notice is not, as the context might imply, from the chapter on the dispersal of plants but from an earlier chapter, and from the very pages of it in which the "critical consideration" he desires is, in fact, given at some length.

FRACTIONAL DISTILLATION AND ITS APPLICATION IN THE CONCENTRATION OF THE HEAVY ISOTOPES OF OXYGEN AND HYDROGEN

By DR. I. DOSTROVSKY, PROF. E. D. HUGHES
AND
DR. D. R. LLEWELLYN
University College of North Wales, Bangor

IN a previous communication[1] we described a convenient type of fractionating column suitable for the concentration of the heavy isotopes of oxygen and hydrogen in water. The glass assembly was efficient for comparatively slow distillations and was capable of producing valuable enrichments of O^{18} in sufficient quantities of water to be useful for tracer studies. A column 12 ft. in length and ¾ in. in diameter had efficiency equivalent to about 450 theoretical plates for a boil-up rate of 500 ml. per hour, and, to give an illustration of its performance, in twenty-four days of continuous distillation at atmospheric pressure it produced 500 ml. of water with nearly a three-fold enrichment of O^{18}. As expected, the production of the desired isotopes is increased by operating the column under reduced pressure. Thus, a five-fold enrichment of O^{18} is obtained after six weeks of continuous distillation at 150 mm. pressure. A further increase results by periodically replacing the reservoir water (which becomes lighter during the course of an experiment) by fresh water. It is more convenient, however, to use the same stock throughout a run, and this has generally been our practice with this column.

The successful use of the apparatus prompted us to attempt the construction of a larger column, our aim being to maintain approximately the platage of our first design while increasing the throughput by about ten-fold. Our general intention was to demonstrate the possibilities of such columns in isotopic work and other investigations involving the close fractionation of mixtures. The unsuitability of the radioactive isotopes of oxygen for tracer studies, and the lack of success hitherto experienced in devising other convenient methods for the separation of the stable isotopes of this element in substantial quantities, gave added interest to the application in this instance of the distillation method, which, on the basis of the results of previous investigators[2] and our experience with the smaller column, promised to be especially useful in the case of oxygen. Our immediate target then was to obtain good enrichments of O^{18}, and, in particular, to obtain a rapid supply of sufficient quantities of enriched material for a second-stage concentration in the glass column previously described. An ultimate objective, using various columns in conjunction, is to obtain isotopically pure O_2^{18} and H_2O^{18} for studies of their properties, and to have ample quantities of highly enriched samples suitable for all types of tracer experiments. Accordingly, we have constructed a 30-ft. metal column of 3 in. diameter, suitable for continuous fractionation, and we now wish to place on record its chief characteristics.

The still is designed to operate at reduced pressures with either ordinary distilled water or enriched water as feed stock. The main section consists of a 31-ft. length of 3-in., 16-gauge copper pipe, and contains a 30-ft. portion filled with 100-mesh phosphor-bronze packing, as in the column previously described[1]. The remaining length accommodates the inlet from a feed pipe, the outlet to an overflow pipe and a short reflux condenser, the last two items being used only in connexion with the flooding process. The top of the column is connected to a pipe leading to the main condensers, from which another pipe carries the condensate to a reservoir situated on the level of the base of the column. In the first mode of operation, the condensate displaces from the reservoir (containing enriched material in this case) an equal volume of water, which is conveyed through the feed pipe to the top of the column. In the second method, the displaced water is run into distilled water containers (and may be used for ordinary laboratory purposes), while fresh distilled water is fed to the top of the column through a flowmeter[3] which records and automatically controls the rate of flow. With this column, which is especially useful for the first stage of concentration, we generally employ the latter method.

The water flowing down the column is led through a glass tube to the bottom of the boiler, which consists of a 'Pyrex' tube, 18 in. in length and 2¾ in. in diameter, containing four one-kilowatt tubular heaters. The boiler has a working volume of 200 ml. of water, and a level-controlling device is incorporated which keeps this volume sensibly constant. The vapour is returned to the bottom of the column through a copper tube (diameter 1 in.). A connexion is taken from this tube to a manometer and to one side of a differential manometer, the other side of which is connected to the top of the condenser, to a manostat and to the vacuum line. Samples of water can be removed from the boiler through a side tube and valve.

Thermal insulation of the column is provided by 'Fibreglass' pipe lagging (2½ in. thick) built in two layers with a compensating electric heater wound on the inner layer. The input of this electric heater is controlled by a 'Simmerstat' and adjusted to compensate for the residual heat loss. A number of thermocouples and differential thermocouples are incorporated throughout the length of the jacket as an aid to the correct adjustment of the jacket heater.

The centre section of the column is fixed to the wall of a laboratory, the upper portion extending to the top of a ventilator on the roof, while the lower section passes through a hole in the floor of the laboratory to a basement below, where it is supported by a brick structure.

Since it is necessary to operate the column for long periods without attention, it is essential to safeguard the equipment from damage and the enriched water from loss consequent upon failure of water or electricity supply or breakdown in parts of the apparatus; accordingly, appropriate safety devices and automatic controls are incorporated.

The following details indicate the achievements of the column in preliminary runs on the first-stage fractionation of water. The distilled water feed-rate was 3,850 ml./hr. and the pressures in the boiler and at the top of the column were 460 mm. and 290 mm of mercury respectively. We give two illustrations of the performance of the still in production experiments. After sixteen days of continuous distillation the boiler contained approximately 1 per cent H_2O^1 (excess density (H_2O^{18}) = 755 p.p.m.; enrichment nearly five-fold) and, thereafter, 115 ml. of water of this quality could be withdrawn daily for further concentration. (Using the column previously described[1], a second-stage fractionation of water obtained in this manner is expected to yield 5 per cent H_2O^{18}.) The operating conditions, which were intended to be suitable for O^{18} enrichment, were not particularly appropriate for the production of deuterium, but it is of interest to record that after the same period (16 days) the boiler water in the first stage of distillation contained 3 per cent of HDO. The daily withdrawal of 115 ml. of water afterwards reduced this figure to a steady value of 1·1 per cent (excess density (HDO^{16}) = 560 p.p.m.; enrichment factor = *c.* 32). After thirty-two days of continuous distillation, a six-fold enrichment of O^{18} was obtained in the boiler water, while the deuterium concentration was about 180 times the normal value. At this point, 30 ml. of water of approximately the same quality in O^{18} (excess density (H_2O^{18}) = 1,073 p.p.m.) could be withdrawn daily from the still, but this rate of removal lowered the deuterium enrichment to about 140 times the normal value (excess density (HDO^{16}) = 2,530 p.p.m.; HDO = 5 per cent). If applied appropriately in conjunction with the electrolytic process, the use of the distillation method, employing suitable modifications and enlargements of the type of still described, may be of value in the production of pure deuterium oxide. This and similar applications are being further explored.

When no water is withdrawn from the boiler the enrichment (q') of O^{18} is represented approximately (except for small t values) by the equation

$$q' = 6{\cdot}80 - 5{\cdot}45\exp(-t/16) - 0{\cdot}18\exp(-t/0{\cdot}77) - \ldots,$$

q' being the ratio of the concentrations of O^{18} in the boiler water and in the feed-stock and t the time in days from the commencement of the run. Except for small values of t, the first two terms of the expression provide a useful approximation formula for q'. The enrichment of deuterium (q'') over the range examined approximately follows the linear relationship $q'' - 1 = 5{\cdot}64\ t$, q'' representing the ratio of concentrations of deuterium in the boiler water and in the feed-stock and t being measured in days as before. Assuming a value of α, the ratio of the vapour pressures of H_2O^{18} and H_2O^{16}, deduced from the data of Wahl and Urey[4], namely, 1·0044, the efficiency of the column under the conditions described is equivalent to about 435 theoretical plates. An analysis of our results, however, indicates a considerably higher value of α than that deduced from the data of previous workers[5]. Discussion of this point is postponed pending the results of further investigations.

A detailed description of the construction and characteristics of the column will be published elsewhere.

We wish to thank Imperial Chemical Industries, Ltd., Billingham Division, for advance information concerning the operation of their metal-gauze-packed fractionation columns[6].

REVERSAL OF VERNALIZATION BY HIGH TEMPERATURE

By Prof. F. G. GREGORY, F.R.S.,
AND
Dr. O. N. PURVIS
Imperial College of Science and Technology

IN a previous letter[1], evidence was presented showing that 'Petkus' winter rye vernalized for six weeks and then exposed for a short period (1–4 days) to a temperature of 35° C. showed a retardation of flowering, thus indicating a partial reversal of the vernalized condition. The complete devernalization reported by Efeikin[2] and Tetjurev[3] using winter wheat was not obtained in this experiment with winter rye. After a period of vernalization of twelve weeks, however, high temperature completely failed to cause retardation in flowering. The conclusion was therefore drawn that as the period of low temperature treatment is extended the vernalized condition induced becomes less and less easily reversible and finally is completely stable. This suggestion has been completely substantiated by an experiment carried out in 1947. Winter rye was vernalized for varying periods, using the 'restricted moisture' method, and at the end of treatment was exposed for three days to a temperature of 35° C. The grain was then sown, both in the field and in pots, and the flowering behaviour assessed by the 'scoring method' of Gregory and Purvis[4], which gives a quantitative measure of 'earliness' of flowering. The results for plants grown in the field are presented in Table 1.

TABLE 1. RETARDATION OF WINTER RYE VERNALIZED FOR DIFFERENT PERIODS AND THEN HEATED TO 35° C. FOR 3 DAYS. FIELD CULTURE. NUMBER OF REPLICATES IN BRACKETS

Duration of vernalization	'Scores' Unheated	'Scores' Heated	Difference	Degree of vernalization	% reduction by heat
0 (Control)	24±1·4 (42)	24±0·9 (43)	—	—	—
2 weeks	28±2·6 (40)	24±1·3 (34)	3·2±3·1	4	100
3	62±4·4 (59)	41±3·9 (45)	22·2±6·1	38	58
4	79±4·6 (56)	48±5·3 (44)	30·5±7·0	55	55
5	108±1·1 (42)	87±5·5 (38)	21·2±5·4	84	25
6	112±0·8 (48)	98±3·0 (49)	13·8±3·1	88	16
8 (5 days heat)	121±0·5 (53)	118±1·0 (45)	3·0±1·1	97	3

High temperature following on all periods of vernalization, except the shortest (two weeks), led to a retardation in flowering which was statistically significant; two weeks of vernalization failed to give a significant acceleration of flowering and therefore no subsequent reversal by heat could be expected. The figures entered in column 2 of the table show the usual effect of increasing duration of vernalization upon the acceleration of flowering; those in column 3 the 'scores' for plants grown from the grain heated after vernalization; by difference the effect of the subsequent heat treatment on the 'score' is obtained and entered in column 4. The degree of vernalization of the unheated grains is shown in column 5, and the reversal of vernalization by heat is entered in column 6. The progressive reduction in the effect of the heat

TABLE 2. RETARDATION OF WINTER RYE VERNALIZED FOR DIFFERENT PERIODS AND HEATED AT 35° C. FOR 3 DAYS. POT CULTURE. NUMBER OF REPLICATES IN BRACKETS

Duration of vernalization	'Scores' Unheated	'Scores' Heated	Difference	Degree of vernalization	% reduction by heat
0 (Control)	26±3·0 (5)	34±4·0 (6)	−8·2±5·2	—	—
2 weeks	58±10·9 (7)	31±4·1 (10)	27·0±10·3	32	84
3	89±6·2 (8)	69±9·5 (9)	20·4±11·6	63	32
4	113±2·5 (11)	96±5·0 (7)	17·1±4·4	87	20
6	118±1·5 (8)	114±4·7 (10)	4·3±5·4	92	4

treatment as vernalization is prolonged is very apparent. Similar results obtained with plants grown in pot culture are given in Table 2.

Replication in this experiment was much reduced by attacks of frit fly; but the numbers surviving were adequate to establish the significant devernalization by heat and the progressive decline in effect of heat with prolongation of vernalization treatment. The higher 'scores' usually found with plants in pot culture[5] have made possible a demonstration of devernalization after two weeks low-temperature treatment.

The leaf numbers for the pot culture plants are entered in Table 3.

TABLE 3. INCREASE IN LEAF NUMBER IN PLANTS VERNALIZED FOR DIFFERENT PERIODS AND THEN HEATED TO 35° C. FOR 3 DAYS. POT CULTURE. NUMBER OF REPLICATES IN BRACKETS

Duration of vernalization	'Scores' Unheated	Heated	Difference
0 (Control)	21·8±0·34 (5)	21·2±0·56 (6)	−0·6±0·98
2 weeks	19·2±1·61 (7)	22·3±0·47 (10)	3·1±1·34
3	16·2±0·38 (8)	19·8±0·73 (9)	3·6±1·09
4	12·7±0·26 (11)	18·0±2·57 (7)	5·3±0·41
6	10·8±0·45 (8)	11·8±0·53 (10)	1·0±0·91

After two, three and four weeks vernalization, subsequent heat treatment has significantly increased the leaf number, which affords conclusive evidence that retardation in flowering results from a true reversal of vernalization rather than from a mere retardation of growth-rate of the plants. A similar increase in leaf number following devernalization by heat has been noted in wheat by Efeikin[6].

Experiments on devernalization have been carried out in four successive years and have given variable results; in 1946 the reversal was insignificant despite the fact that the response to vernalization was quite normal and similar to the values for 1947 presented above. The cause of this variation is still being investigated, and there is evidence to show that the stability of the vernalized condition increases with the degree of development taking place during the low-temperature treatment, since far more reversal occurs when the grains are prevented from growing by restricting the moisture supply during vernalization than when vernalized in moist sand with unlimited water supply. Thus two lots of vernalized grain may be alike in flowering response but differ in stability of the vernalized condition. On the other hand, it is possible that the differences noted were due to revernalization by low temperature encountered after planting out the grain; for Efeikin[6] has pointed out that, in wheat, revernalization after a partial devernalization by high temperature takes place more rapidly than the original vernalization, and a similar result with Petkus rye has been obtained by us, which thus would greatly augment the effect of such low temperatures after planting out.

It is clear that any attempt to formulate the reactions resulting in vernalization must take into account this gradual establishment of an irreversible condition of vernalization; its practical importance in relation to effects of sowing date upon time of flowering of vernalized grain has been indicated elsewhere[5].

U.S. NATIONAL ACADEMY OF SCIENCES

Election of Officers and Members

AT the annual meeting of the U.S. National Academy of Sciences held in Washington during April 26–28, the following officers, members and foreign associates were elected:

Treasurer (July 1, 1948–June 30, 1952): William J. Robbins, director of the New York Botanical Garden. (The other officers of the Academy are: *President:* Alfred N. Richards; *Vice-President:* L. P. Eisenhart; *Foreign Secretary:* Detlev W. Bronk; *Home Secretary:* Fred. E. Wright.)

Members of the Council of the Academy (for a three-year term ending June 30, 1951): Carl R. Moore, professor of zoology, University of Chicago; and J. Robert Oppenheimer, director of the Institute for Advanced Study, Princeton, New Jersey. (Other members of the Council are: Alfred N. Richards, L. P. Eisenhart, Detlev W. Bronk, Fred. E. Wright, William J. Robbins, W. R. Miles, W. Albert Noyes, jun., I. I. Rabi, and Donald D. Van Slyke.)

Members: Eric G. Ball, professor of biological chemistry, Harvard Medical School; Lloyd V. Berkner, chairman of the Section of Exploratory Geophysics of the Atmosphere, Carnegie Institution of Washington; Felix Bloch, professor of physics, Stanford University; Gerty T. Cori, fellow and research associate in pharmacology and biochemistry, Washington University School of Medicine; Hallowell Davis, director of research, Central Institute for the Deaf, research professor of otolaryngology, Washington University; John R. Dunning, professor of physics, Columbia University; W. Maurice Ewing, head of the Department of Geophysics, Columbia University; Karl Folkers, assistant director of research, Merck and Co., Rahway, New Jersey; Thomas Francis, jun., professor of epidemiology and chairman of the department, School of Public Health, University of Michigan; Edwin R. Gilliland, professor of chemical engineering, Massachusetts Institute of Technology; Haldan K. Hartline, associate professor of biophysics, Hospital of the University of Pennsylvania; Ernest R. Hilgard, chairman of the Department of Psychology, Stanford University; Frank L. Horsfall, jun., member, Rockefeller Institute for Medical Research, New York; John R. Johnson, professor of chemistry, Cornell University, New York; Raymond A. Kelser, dean of the School of Veterinary Medicine and professor of bacteriology, University of Pennsylvania; Cyril N. H. Long, chairman of the Department of Physiological Chemistry, Yale University School of Medicine; Edward J. McShane, professor of mathematics, University of Virginia; Donald H. Menzel, chairman of the Department of Astronomy, Harvard University, and associate director for solar research, Harvard College Observatory; C. W. Metz, chairman of the Department of Zoology, University of Pennsylvania; Curt P. Richter, associate professor of psychobiology Johns Hopkins University; Hermann I. Schlesinger professor of chemistry, University of Chicago Francis O. Schmitt, head of the Department of Biology and Biological Engineering, Massachusetts Institute of Technology; Glenn T. Seaborg, professor of chemistry, University of California, Berkeley Gilbert M. Smith, professor of botany, Stanford University; Curt Stern, professor of zoology, Univer sity of California, Berkeley; Chester Stock, professor of palæontology, California Institute of Technology; James B. Sumner, professor of biochemistry, Cornell University; Edward Teller, professor of physics, University of Chicago; Kenneth V. Thimann, associate professor of botany, Harvard University; Charles A. Thomas, executive vice-president, Monsanto Chemical Co., Dayton, Ohio.

Foreign Associates: Ronald Aylmer Fisher, Arthur Balfour-professor of genetics in the University of Cambridge; Prince Louis de Broglie, professor of theoretical physics, University of Paris (Sorbonne).

Medal Awards

Henry Draper Medal. The Henry Draper Medal for 1947 was conferred on Hans Albrecht Bethe, professor of physics at Cornell University, in recognition of his contributions to astronomical physics, more especially his researches on the generation of energy in the sun and stars. Since the first development of the concept of energy, one of the outstanding problems of the physical sciences has been that of the source of the tremendous flow of energy from the sun and stars. Dr. Bethe gave a brilliant, quantitative solution to this problem in terms of the nuclear transformation of hydrogen into helium, with carbon and nitrogen serving as catalysts. Dr. Bethe has furthermore used this solution to extend our knowledge of stellar interiors.

The Henry Draper Fund was established in 1883 for the purpose of striking a gold medal to be "awarded and presented from time to time by the said National Academy of Sciences to any person in the United States of America or elsewhere who shall make an original investigation in astronomical physics of sufficient importance and benefit to science to merit such recognition".

Agassiz Medal. The Agassiz Gold Medal and Honorarium for 1947 were conferred on Felix Andries Vening Meinesz, professor of geodesy and geophysics in the University of Utrecht, and president of the Netherlands Geodetic Commission, for his contributions to oceanography (see *Nature*, **160**, 169; 1947).

The Sir John Murray Fund was established in 1911 "for the purpose of founding an Alexander Agassiz gold medal, to be awarded for original contribution in the science of oceanography to scientific men in any part of the world, whenever and as often as the President and the Council may deem desirable".

Walcott Medal. The Charles Doolittle Walcott Bronze Medal and Award for 1947 were conferred on Dr. Alexander G. Vologdin, of the Palæontological Institute in Moscow. Dr. Vologdin was chosen because of his studies of Pre-Cambrian and Cambrian algæ, and particularly because of his researches on that most distinctive and enigmatic group of Cambrian organisms, the Archæocyatha. When Dr. Vologdin began his studies these early organisms were supposed to be rare and unimportant in the U.S.S.R., but he soon saw in collections brought back from central Siberia and from the southern Urals a rich field for investigation. His early results stimulated interest, and new discoveries of Cambrian formations were made in rapid succession from the Urals to the Altai and from Mongolia to Arctic Siberia. Dr. Vologdin personally made large collections of algæ and Archæocyatha from certain of these deposits, but his collections grew also by the additions from other field parties. Meanwhile, his first large monograph, "The Archæocyathinæ of Siberia", in 1931 almost doubled the known fauna of these organisms for the world. So early as 1937, when the known Archæocyatha of the world totalled approximately 400 species, some 250 were due to Dr. Vologdin. As a result of his brilliant achievements the Government of the U.S.S.R. in 1943 established a special laboratory at Moscow expressly for research in the Archæocyatha and the Pre-Cambrian and early Palæozoic algæ.

The Charles Doolittle Walcott Fund was established "to encourage and reward individual achievement in advancing our knowledge of Pre-Cambrian and Cambrian life in any part of the world". The deed of gift provides that nomination be made by a board of five, one of whom shall be appointed by the Royal Society of London, one by the Institut de France, two by the president and council of the U.S. National Academy of Sciences, and the secretary of the Smithsonian Institution.

NORMAN LOCKYER OBSERVATORY OF THE UNIVERSITY COLLEGE OF THE SOUTH WEST OF ENGLAND, EXETER

THE arrangements for transferring control of the Norman Lockyer Observatory to the University College of the South West (see *Nature* of January 3, p. 15) came to fruition on May 1, when the transfer was formally completed at a joint meeting of the two institutions. Sir Richard Gregory (chairman of the Observatory Corporation) gave possession, control and management of the Observatory to the College, and this was accepted on behalf of the College by Sir William Munday, deputy president. A new stage has thus been reached in the history of a unique attempt to develop, by private enterprise, an institution for pure research with no industrial applications.

The Observatory was founded in 1912 through the energy and foresight of Sir Norman Lockyer who, with Lady Lockyer and a small band of enthusiasts, presented land, money, instruments and practical services to the new enterprise. These early benefactors included, among others, Sir Francis McClean and his brother, Capt. W. N. McClean, who has acted as honorary secretary since the foundation. They were later joined by others and formed a Corporation under the Companies (Consolidation) Act, 1908, with articles of association approved by the Board of Trade. In spite of severe setbacks occasioned by the two world wars, the Observatory has not only survived but even developed to a considerable extent with the help of occasional short-term grants and the generosity of additional donors. Among the latter may be mentioned Sir Robert Mond, who made considerable gifts of money and equipment; also Lady Lockyer, who bequeathed the whole of her residuary estate to the Observatory, finally bringing the capital funds of the Observatory to about £40,000 in addition to about 44 acres of freehold land and much valuable equipment.

The astronomical equipment includes two twin equatorial refractors, each with a visual telescope of 10 in. aperture and an objective prism telescope (apertures 12 and 9 in. respectively) for photographing stellar spectra; also an astrographic instrument with four Zeiss lenses for direct photography, several smaller telescopes and two 12-in. siderostats. A 30-in. reflector, by Common, and a 6-in. Cooke refractor have not yet been erected. In the laboratory is a fine recording microphotometer by Casella, a 3-prism Littrow spectrograph, various measuring micrometers and much miscellaneous apparatus. There is an excellent library, containing most of the astronomical literature published since 1912, as well as a large proportion of earlier publications from the libraries of Sir Norman Lockyer and Dr. Frank McClean.

The scientific work has been carried out by a staff which, though enthusiastic, has always been very small, consisting of a director and usually either one or two assistant astronomers. At some periods no assistants were available. The first director, Sir Norman Lockyer, was succeeded by his son, the late Dr. W. J. S. Lockyer, and Mr. D. L. Edwards (the present director). These, with their small band of colleagues, have developed the Observatory until, in the words of the Astronomer Royal, "it has earned for itself an important place in British astronomy" —an importance which is recognized throughout the world in scientific circles.

A measure of the vitality of such an institution is afforded by the number of original communications from it accepted and published by scientific societies. About forty such papers were published under the directorship of Dr. Lockyer during 1920–36, and this rate of output has been maintained, as about thirty papers have been published since that period. The amount of night-work involved may be judged from the fact that more than 10,000 photographs (mostly of stellar spectra) are now available for reference and further study—a collection which is possibly unequalled in Great Britain. All this has been built up and maintained through the generosity of private persons; but in the present world conditions further development in this way is unlikely, so that the transfer to the University College will not only place the Observatory on a permanent responsible foundation but also give the best possible chance of future expansion.

The method of achieving the transfer, however, namely, by keeping the Corporation in existence but allowing a decisive majority on its Council to Exeter representatives, retains a pleasing link with the past and leaves a convenient channel available to any further flow of benefactions from private enterprise, great or small, should that arise in the future. It also retains the possibility of enlisting the interest and active assistance of leading British astronomers in the Observatory. Many of the most eminent of these have given valuable help from the beginning, by serving on the Council or Research Committee or in other ways, and the Council of the new Corporation still includes a number of well-known astronomers who are prepared to give active support in a similar way.

The University College authorities, on their side, are to be congratulated on acquiring such a well-established institution for astronomical research, with considerable endowments—a possession which is unequalled in any but the older universities. This was fully recognized by Sir William Munday, who regarded the union as an important milestone in the progress of the College and as helping it to obtain the full university charter which is desired. The responsibilities attached to the gift are also fully realized, and it is the intention of the College to do everything possible not only to maintain but also to develop the Observatory in the future. The event is thus of mutual benefit to the institutions concerned and also, it is to be expected, to astronomical research in Britain. The considerable advancements in this direction made in the past should receive additional impetus and it will always be remembered (in the words of a vote of thanks proposed by the Astronomer Royal) "that these achievements constitute a lasting memorial of gratitude to the spirit of the donors".

LONG ASHTON RESEARCH STATION

THE annual report for 1946 of the Agricultural and Horticultural Research Station, Long Ashton, Bristol, marks a year of change, when members of the advisory staff were transferred to the National Agricultural Advisory Service at Bracken Hill, Leigh Woods, close to the Station. This proximity should allow continued close liaison.

Several studies deal with nutrition of fruit and vegetable crops. An interesting result of work by E. J. Hewitt is that symptoms of acid damage are largely those of excess manganese and low calcium. T. Wallace, W. Morley Davies, D. J. D. Nicholas and E. J. Hewitt show that liming will correct this trouble; but residual deficiencies of magnesium, potash, phosphorus and nitrogen will still require treatment. Inorganic fertilizers are compared with organic manures such as sewage sludge, town refuse, and straw composted with sewage sludge, by C. Bould and E. Catlow. This is part of a long-term experiment on cultural systems for apples and black currants.

L. C. Luckwill has found that the methyl ester of alpha-naphthalene acetic acid will delay sprouting of stored potatoes. Spring treatment is effective at the rate of ½ oz. per ton, and its use would seem economically feasible for certain purposes. An important feature about winter wash emulsions is their resistance to rain, and S. H. Bennett, H. G. H. Kearns and H. Martin find, *inter alia*, that dinitrocresol washes are more rain-proof than tar-oil emulsions.

A detailed study of hop diseases and pests in the west Midlands is being made by E. H. Wilkinson, who is investigating virus diseases and the condition known as split leaf blotch, and J. F. Southey, who surveys the insects associated with this crop. J. A. H Tolhurst has surveyed the incidence of the virus disease nettlehead in relation to soil conditions and nutritional status of the plant. Preliminary results suggest that there may be a correlation with soil types, but none between the amounts of nitrate nitrogen, phosphate, potassium, calcium and magnesium in the host plant. Serious losses of field beans have been caused by chocolate spot disease, and L Ogilvie and M. Munro suggest manuring with phosphate and potash, and the avoidance of close, sheltered sites, as measures against the trouble. M. Miles discusses the importance of the bean seed fly in England and A. Stringer makes the interesting point that mature *Solanum polyadenium* plants are immune from aphid attack largely because a gummy secretion from the plant clogs the legs of the aphids.

An important aspect of the Station's work is its investigation of factors affecting quality of fresh and preserved fruit and vegetables. M. E. Kieser and A Pollard find that from one half to two thirds of the vitamin C in apples is retained on cooking, and the largest amounts of this vitamin occur in cider varieties. J. D. Bryan reports that the organic acid in plums and apples is almost all malic, in black currants chiefly citric, whereas gooseberries and tomato have a mixture of the two. Some potato varieties blacken on cooking, and have unsuitable texture; A. Pollard, M. E. Kieser and B. A. Crang show that cooking quality is mainly dependent on site, and the correction of manurial deficiencies improves the quality if its initial level was sufficiently high.

It seems appropriate that the report should close with a historical account, by R. W. Marsh, of the advisory agricultural services of the University of Bristol, which have been in operation since 1912; they have gradually gained the increasing confidence of farmer and grower, and should proceed to an even more useful future under the National Agricultural Service.

INTERNATIONAL ASPECTS OF THE RADIO-FREQUENCY SPECTRUM

During the summer of 1947, a series of International Telecommunication and Radio Conferences were held at Atlantic City, U.S.A., and the proceedings and conclusions of these have recently been published from the headquarters of the International Telecommunications Union at Berne, Switzerland. The object of these conferences was to revise the radio-communication regulations and the convention last formulated at Cairo in 1938 (see *Nature*, **141**, 195; 1938), and to re-plan the allocation of radio frequencies for the many and varied applications in use at the present time. A summary of the findings of the Atlantic City Conferences, which were attended by nearly thirty British delegates under the leadership of Sir Stanley Angwin, is given in the April issue of the *Wireless World*.

Since the drafting of the Cairo regulations, the radio-frequency spectrum has been extended very considerably at the high-frequency end, while many fresh applications have arisen for which it is necessary to find frequencies either for exclusive use or for sharing with other services in the same or other parts of the world. Under the new regulations, specific provision is made for radio navigation systems, for radio aids to meteorology and for the transmission of standard frequencies of very high accuracy. In addition, certain limited bands have been designated for industrial, scientific and medical equipment: for Great Britain, and in some cases elsewhere, the frequencies assigned for these purposes are 13·56, 27·12, 40·68, 2450 and 5850 Mc./s. Within these bands, any emission from apparatus used for industrial, scientific and medical purposes enjoys priority over other services operated within the bands. Elsewhere in the spectrum, all such apparatus must presumably be screened or operated in such a manner as to avoid any interference with other radio services.

For the purpose of frequency allocations for the many types of communication, broadcasting, radar and navigational aids, the world was divided at Atlantic City into three regions. Region 1 comprises Europe, the U.S.S.R. territory outside Europe, the Mongolian Republic and Asia Minor and Africa; Region 2 covers the whole of the western hemisphere from Greenland to Hawaii; while Region 3 comprises Australia, New Zealand, Oceania and that part of Asia not included in Region 1. It has also been found necessary to re-define and extend the zone in which certain frequencies are allocated for Tropical Zone broadcasting.

A most useful guide to the radio frequency allocations made at Atlantic City has been issued by the Radio Corporation of America in the form of a coloured chart. This chart covers the spectrum between 10 kc./s. (wave-length 30 km.) and more than 30,000 Mc./s. (wave-length 1 cm.); and it shows for each of the three regions described above the bands of frequencies proposed for twenty-three different services. It is to be noted that no specific allocations are yet proposed above 10,500 Mc./s., such higher frequencies being still regarded as for experimental purposes. While some of the allocations are already in being, it is recommended that the provisions become effective during 1949. One of the most important outcomes, however, of the Atlantic City conferences was the decision to set up an International Frequency Registration Board, which has already begun its task of examining all notifications of the proposed use of frequencies with the view of including those approved in the Master International Frequency Register. In addition to dealing with the allocation of frequencies, the new regulations contain a number of new definitions of the terms now used in radio engineering and scientific work, and also a revised classification of the various portions of the radio spectrum, and of the types of transmission and the systems of modulation now in common use.

Bearing in mind the extent and complexity of modern telecommunications technique, it must be a source of satisfaction to all those who participated in the conferences that such a large measure of agreement has been obtained on the methods of conducting world-wide radio communications.

FORTHCOMING EVENTS

Monday, May 31

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5.30 p.m.—"Photo-Canada" (Kodachrome Film with Sound Commentary).

Wednesday, June 2—Saturday, June 5

Textile Institute (at Buxton).—Conference on "The Organisation of the Textile Industry and Textile Production".

Thursday, June 3

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Messrs. E. R. Andrew, M. Desirant and D. Shoenberg: "The Intermediate State of Superconductors".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 5.15 p.m.—Annual General Meeting.

Chemical Society (at the Royal Institution, 21 Albemarle Street, London, W.1), at 7.30 p.m.—Prof. L. C. Pauling, For.Mem.R.S.: "The Modern Theory of Valency" (Liversidge Lecture).

Friday, June 4

Physical Society (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Sir George Thomson, F.R.S.: "The Growth of Crystals" (32nd Guthrie Lecture).

Geologists' Association (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Dr. F. J. North: "A Cave near Aberdare, Glamorgan; Geological Notes and Queries".

Institution of Electronics, North-Western Branch (in the Reynolds Hall, College of Technology, Manchester), at 6.30 p.m.—Mr. L. C. Jesty: "Television".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Secretary and Registrar—The Secretary and Registrar, University College of North Wales, Bangor (June 5).

LECTURER (Grade I) IN ZOOLOGY—The Secretary, The University, Edmund Street, Birmingham 3 (June 7).

RESEARCH ASSISTANT to work under the direction of the Professor of Surveying and Photogrammetry on a programme of research into Altimetry in its relation to Photogrammetry—The Secretary, University College, Gower Street, London, W.C.1 (June 10).

ASSISTANT TECHNICAL EXAMINING OFFICER (male) IN THE VICTUALLING DEPARTMENT of the Admiralty—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2166 (June 10).

UNIVERSITY LECTURER and a UNIVERSITY DEMONSTRATOR IN PHYSICAL CHEMISTRY—The Secretary of the Appointments Committee, Faculty of Physics and Chemistry, Chemical Laboratory, Cambridge (June 12).

ASSISTANT LECTURER (grade III) IN THE DEPARTMENT OF PSYCHOLOGY—The Registrar, The University, Liverpool (June 12).

ASSISTANT PRESS OFFICER (unestablished) at Headquarters of the Department of Scientific and Industrial Research, London—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting G.159/48 A (June 14).

SENIOR PRINCIPAL SCIENTIFIC OFFICER in the Royal Naval Scientific Service to undertake theoretical and experimental research in hydrodynamic problems—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2167 (June 14).

LECTURER IN MATHEMATICS in University College, Dundee—The Secretary, The University, St. Andrews (June 15).

SENIOR EXAMINERS (temporary) at the Ministry of Supply A.I.D. Test House, Harefield, Middx.—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.344/48A (June 15).

SENIOR ENTOMOLOGIST-IN-CHARGE, an ENTOMOLOGIST, and a CHEMIST, in a Research Unit proceeding to Mauritius to undertake a large-scale mosquito eradication experiment using D.D.T. and B.H.C. insecticides—The Under-Secretary of State, Colonial Office (Research Department), Palace Chambers, Bridge Street, London, S.W.1 (June 21).

SENIOR SCIENTIFIC OFFICER IN THE DEPARTMENT OF PARASITOLOGY AND CHEMOTHERAPY, and a SCIENTIFIC OFFICER IN THE DEPARTMENT OF PHYSIOLOGY, CHEMISTRY, ANIMAL HUSBANDRY AND ANIMAL BREEDING, East African Veterinary Research Organisation, Kenya—The Under-Secretary of State, Colonial Office (Research Department), Palace Chambers, Bridge Street, London, S.W.1 (June 21).

LECTURER IN THE DEPARTMENT OF BOTANY—The Secretary, The University, Aberdeen (June 25).

CHAIR OF MINING—The Secretary, The University, Edmund Street, Birmingham 3 (July 1).

ASSISTANT and ASSOCIATE PROFESSORSHIPS IN THE DEPARTMENT OF PHYSICS—The Head, Department of Physics, University of British Columbia, Vancouver, B.C., Canada.

LECTURER, and a DEMONSTRATOR, IN THE DEPARTMENT OF BACTERIOLOGY AND IMMUNOLOGY—The Dean, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

METEOROLOGICAL FORECASTERS in the West African Meteorological Service—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

CHIEF OFFICER OF THE OFFICIAL SEED TESTING STATION for England and Wales, and a SECOND ASSISTANT to the Chief Officer—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

PHOTOMICROGRAPHER (male) for senior appointment in technical grade—The Administrative Officer, National Institute for Medical Research, Hampstead, London, N.W.3.

ANALYTICAL CHEMISTS—The Director of Research, British Rubber Producers' Research Association, 48 Tewin Road, Welwyn Garden City, Herts.

ASSISTANT LECTURER IN AGRICULTURE, a DEMONSTRATOR IN POULTRY HUSBANDRY, an ASSISTANT LECTURER, and a SENIOR LABORATORY ASSISTANT, IN THE DEPARTMENT OF BOTANY—The Registrar, University College, Nottingham.

SOIL CHEMIST AND HEAD OF THE CHEMISTRY DEPARTMENT—The Bursar, Royal Agricultural College, Cirencester.

ASSISTANT ELECTRICAL ENGINEER IN THE PLANT ENGINEERING DIVISION—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, endorsed 'Plant Engineering Division'.

INDUSTRIAL CHEMIST, and a CIVIL ENGINEER—The Staff Section, Ministry of Supply, Department of Atomic Energy, Risley, Warrington, Lancs.

SCIENCE AND HISTORY

THE plea for a historical approach in teaching science which Dr. J. B. Conant advanced in his Terry Lectures at Yale University, which have now been published under the title "On Understanding Science"*, raises questions of interest to many besides those who are concerned with teaching itself. Dr. Conant is indeed urging the use of case-histories in teaching science, and illustrates his proposal by the specific example of seventeenth-century experiments on the 'spring of the air' with barometers, air pumps and vacua to show the influence of new techniques, the evolution of new concepts from experiment, the difficulties of experimentation and the significance of the controlled experiment, and the development of science as an organised social activity. These points are further emphasized by a study of the discovery of the electric battery and of the chemical revolution which placed our knowledge of combustion on a sound basis, in which he shows further how an accidental discovery may lead by a series of well-planned experiments to a new technique or a new concept, or both. In exploring a new phenomenon, the experiments may be well planned without any working hypothesis as to the nature of the phenomenon ; furthermore, a useful concept may even be a barrier to the acceptance of a better one if it be long entrenched in the minds of scientific men. Experimental discoveries, he believes, must fit the times ; facts may be at hand for years without their significance being realized ; the total scientific situation must be favourable for the acceptance of new views.

These principles in the tactics and strategy of science are of great importance in the education of the scientific worker himself, and it might be urged that they should be considered with special care by those responsible for the training of the social scientist. They are equally important for the education of the layman, and in conveying to him a clear understanding of what science can and cannot accomplish, and how it works ; for on such understanding the smooth functioning of a democracy largely depends. Dr. Conant argues cogently that, in this way, by clarifying popular thinking about the methods of science, as well as by assisting those in positions of authority and responsibility and those who shape opinion to gain some understanding of science, we should go far to lay the basis for a fruitful discussion of the ways in which rational methods may be applied to the study and solution of human problems.

Even if that is claiming too much, there can be no doubt as to the value of the historical approach in assisting a better understanding of natural science among laymen, or of the importance of such an understanding for the promotion of national welfare. A greater knowledge of the genesis of certain habits of mind should, as Dr. Conant suggests, reinforce slowly but persistently those habits of mind and those rational elements in our civic life which make for the adventurous yet orderly development of our free society. Dr. Conant makes no extreme claims for the widespread application of the scientific method to the problems of society at every level: he recognizes its limitations, and questions, indeed, the validity of Karl Pearson's assertion that "modern science, as training the mind to an exact and impartial analysis of facts, is an education specially fitted to promote sound citizenship"; indeed, he holds that those who have little or no direct experience with scientific investigations might be completely misled as to the nature of the scientific method by studying "The Grammar of Science".

---

* On Understanding Science. By Dr. J. B. Conant. Pp. 162. (London : Oxford University Press, 1947.) 10s. 6d. net.

What Dr. Conant is concerned to promote is just that understanding of the way science works, its difficulties and limitations, which will prevent the distortions which arise when the man of science is put on a pedestal and his activities are regarded as something mysterious or even magical and apart from the ordinary activities of mankind. Incidentally, these few pages are much more suggestive and stimulating in their brief reference to professional tradition and discipline and the rôle of the learned societies in science, as well as in society as a whole, than some of the lengthy but subjective volumes which other authors have devoted to these matters.

Dr. Conant goes right to the heart of the problem of the relation of knowledge to power. He sees clearly that if science is to be used wisely and to take its place among the ordinary activities of mankind, the idea of mystery or magic must be cleared away from the minds of the people. Indeed, so long as any such idea lingers in the popular imagination, the danger of a violent reaction against science and of the social throttling of research, of which Glenn Frank and others have warned us, will persist, and that danger is as great among the Western nations as it is among the more backward peoples.

It is a great merit of the historical approach that it facilitates apprehension of the social implications of science, and there is a passage in the recently issued report on Education for Citizenship in Africa prepared by the Colonial Office Advisory Committee on Education in the Colonies which is strikingly in line with Dr. Conant's thesis. It is not merely among the Colonial peoples that the lesson needs to be learned that man's power over Nature is obtained only by studying and using the facts, and that facts will not consent to adapt themselves to fit a man-made theory; or again, that we should consider the problem of the relationship between the intellectual and the spiritual sides of man's life, between the science of acquiring knowledge and the art of using it.

Burke once reminded us that we do not draw the moral lessons we might from history; and those who realize most fully the extent to which man's material advance has outstripped his spiritual progress have asked with reason whether anything could do more to help to recapture moral control than the universal recognition that physical science belongs in essence to the humanities, is a part, and may become the most important part, of that body of teaching which, though once narrowly confined, was always destined to expand and in unity to embrace the obligations of the good life. In that suggestion, Mr. J. B. Atkin in a recent book, "Incidents and Reflections"*, goes beyond Dr. Conant's arguments; but he is much more convincing than those who, like Dr. G. M. Trevelyan, reject entirely the idea of history as science and contend that history is more a matter of rough guessing from all available facts, dealing with intellectual and spiritual forces which cannot be subjected to scientific analysis, while at the same time they claim that the study of history instils the habit of surveying broadmindedly and calmly the pageant and process of human affairs. It is true, as Dr. G. G. Coulton once remarked, that the more we divorce history from the common life of man, the more we strangle its own vigorous life; but it is equally true that the historian can give no real guidance unless he proceeds from the assembling of facts to generalizations and from generalizations back to facts.

In the simplest and most fundamental way, historical method and scientific method are one and the same, as Mr. A. L. Rowse points out, and the scientific worker concerned to use the historical approach to science or interested in the relations of science and history might do worse than study the two chapters in Mr. Rowse's little book "The Use of History"†, where he brings out the ultimate reason why the study of history and of science is so vital at the present time.

Mr. Rowse suggests tentatively that in spite of all sorts of disillusionments and setbacks, there is an irresistible impulse towards self-government in human society, and he draws the general conclusion from European history that no one power is strong enough to rule all the rest. The sense of history therefore, he suggests, indicates some federal system that may enable us to work together in co-operation. Events in Europe since Mr. Rowse wrote those words in 1945 seem to support the brave assumption that on the basis of a knowledge of history we can look into the nearer future and see something of the shape of things that is emerging, and that such knowledge is the best aid to knowing what we can usefully achieve in our turn.

Mr. Rowse makes that assumption a little too readily, but if the project for a Western Union in Europe is to take concrete shape, the combination of the historian and the man of science, of the historical and the experimental method, may be indispensable. From one must come some guidance as to the behaviour of human groups and the working of human institutions; from the other, and especially the social scientist, must come the closer study of such groups and of individuals in the context of modern society. But both alike will require that the scientific approach be accompanied by the imaginative insight and understanding that marks the great historian no less than the great scientist, if they are to yield their full contribution to the shaping of the new institutions which the world needs to establish order and safeguard its great heritage of freedom and culture from the danger of destruction in war. The historian's work, like that of the man of science, must be sensitive to those human undertones and values which give life its dignity and purpose, and without which the human spirit droops and loses its creative power.

* Incidents and Reflections. By J. B. Atkin. Pp. 258. (London: Christophers, 1947.) 12*s.* 6*d.* net.

† The Use of History. By A. L. Rowse. Pp. xi+247. (London: Hodder and Stoughton, Ltd., 1946.) 4*s.* 6*d.* net.

We need to remember that history is a matter of sense as well as of science, and of feeling as well as of fact; and that both will be required no less in the exercise of citizenship than in the practice of management and administration. We cannot understand why men acted in a certain manner unless we know how they felt; and in discovering where men failed in sympathy and understanding because of such ignorance, we come to the realities of history and indeed of politics, in the widest sense, upon which not merely good citizenship but also good management and administration, and indeed the organisation to serve a new world order, must be based. The historical approach to science helps us to see science in its true perspective in relation to those problems; just as the study of history inculcates that discipline and insight through which alone man can acquire the wisdom and self-command to evolve the forms of organisation which will serve his needs to-day, in industry, in the relations of one nation with another, and in society as a whole.

DEVELOPMENT OF RADAR

Radar System Engineering

Edited by Prof. Louis N. Ridenour. (Massachusetts Institute of Technology, Radiation Laboratory Series.) Pp. xviii+748. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 37*s.* 6*d.*

THOSE who had the privilege of participating in "the tremendous research and development effort that went into the development of radar and related techniques during World War II" are often asked about the effects of that effort in peace-time applications. The effects are of two kinds. The direct use of radar in increasing the safety, speed and economy of transport by air, sea and (perhaps) land is generally appreciated, widely understood and, not infrequently, too optimistically appraised. The indirect effects of radar development or more general radio development are less fully recognized outside specialist circles. Yet it is almost certainly true that these indirect effects will be more important than the direct peace-time applications; they may indeed be comparable in importance to the contribution of radar to victory in the War.

The full benefits of the imaginative skill and initiative, and the 'expertise' which produced, *inter alia*, "the basic microwave and electronic theory and techniques that had been so thoroughly developed during the war-time work on radar" could not be reaped without the further efforts of a distinguished group of the physicists and engineers concerned. The great Radiation Laboratory at the Massachusetts Institute of Technology was itself a monument of scientific co-operation in a great cause. It leaves, as its written memorial to the comparatively few whose names have been quoted in accounts of radar development, and to "the unnamed hundreds and thousands of other scientists, engineers and others who actually carried on the research development and engineering work", a new 'Five-Foot Shelf' not unworthy of a place below the original five-foot shelf of the 'Hundred Best Books'. The generous co-operation of an editorial-cum-author group of about sixty members, which remained at the Massachusetts Institute for more than six months after they might reasonably have chosen to return to their normal peace-time pursuits, and which was supported by a still larger body of contributing authors, has given us a twenty-eight volume series of which Prof. Louis Ridenour's "Radar System Engineering" is, appropriately, the first volume. Appropriately, because the five books dealing with radar and allied systems, and the twenty-two books dealing with special techniques, circuits and circuit elements, which with a twenty-eighth index volume fill the five-foot shelf, all spring from the parent stem of "Radar System Engineering", and are all contributing to the synthesis of radar engineering. The author's preface remarks that this volume serves to specialize to radar the techniques which are described in other volumes of the series.

Ridenour's book will continue to be the best book on the subject when the present and still too thin first crop of books on radar and allied topics has greatly increased. It is an admirably full and balanced survey, at once a general treatise substantially complete in itself, a reference book on design and a guide to the use of the more detailed but more closely canalized papers which are now being added to the tool-kit of the radio worker.

No comparable work has been published, or appears to be contemplated, in Great Britain. The only substantial body of published work on radar yet published in the United Kingdom is contained in the proceedings of the highly successful and stimulating Radiolocation Convention of the Institution of Electrical Engineers, supplemented by a few isolated volumes on special subjects. The British *ensemble* still falls short of being a balanced and comprehensive whole. The American *ensemble* has the enormous advantage of having been carefully planned, before execution, to ensure balance and completeness. It has the major merits, as well as the minor blemishes, of an enterprise in which the whole series is the work of a co-operative team, and in which the typical volume, like the volume under review, is itself the product of a team of authors, each an authority on the subject of which he writes. In the planning, the editing and the writing, the Radiation Laboratory team had the cordial co-operation of their British colleagues, and the author-writer of this volume acknowledges in particular the help of Dr. B. V. Bowden.

If the team method has produced some unevenness in standard, the lowest standard is still high and the average remarkably high. The section on the "Properties of Radar Targets" has no adequate counterpart in British published papers, and that on the "Minimum Detectable Signal" may be cited as an exceptionally searching synthesis of fundamental considerations in design.

The book is extremely well illustrated, and the wealth of photographs of P.P.I. (Plan Position Indicator) displays illustrating a great variety of technical and operational points of importance make a fascinating and excellent album of modern radar.

The book contains much the best, and indeed the only reasonably comprehensive account of the technique developed, in the latter stages of the War, for discriminating between the usually desired responses from moving targets and the usually, but not invariably, undesired responses from substantially fixed targets. This technique of 'moving target indication' will be of great importance in peace-time radar, as, for example, in maintaining continuous observation on civil air traffic by elimination of the 'ground clutter' of 'permanent echoes' which obscure or overlay aircraft echoes.

There is another 'clutter' phenomenon which imposes grave limitations on the general use of radar. The return of radar echoes from rainstorms is a well-known and quantitatively understood cause of impairment of radar search and surveillance. The general problem is well treated in a brief section which ends with a tantalizingly brief indication of results obtained by utilizing, as a discriminant between rain echoes and the echoes from ground targets, the fidelity with which the polarization of the incident radiation is retained in returns from spherical drops, as opposed to the changes in polarization produced by the ground targets. A fuller quantitative account of observations in adequately diverse conditions especially with echoes from aircraft would be welcomed by all radar workers.

This problem of rain-clutter is one, but only one, of a variety of considerations which lead to the only major criticism that can be levelled against the content of a volume entitled "Radar System Engineering". The editor-author says in his preface, "This book is intended to serve as a general treatise and reference book on the design of radar systems. No apology seems to be needed for the fact that it deals primarily—though by no means altogether—with microwave pulse radar. Thousands of times as much work has gone into pulse radar as into any other kind, and the overwhelming majority of this work has been concerned with microwave pulse radar. The superiority of microwaves for almost all radar purposes is now clear." What he means by "microwave" is clear; he means wave-lengths less than ten centimetres. What he means by "almost all radar purposes", if we are to agree with his conclusion, is much less clear. The variety of considerations referred to a moment ago may be journalistically summarized as ranging "from raindrops to V2". Nor was it merely the accidents of time and place that made a large majority of the radar equipment used in the final liberation assault on Europe work on wave-lengths greater than 10 cm.

The truth is that microwave radar is of extreme importance in a majority of all radar operations, but that radar equipments working on wave-lengths from 30 centimetres to about 10 metres are indispensable for operations of crucial importance which cannot be assured even by microwave radar.

There is, throughout the book, a generous and cordial appreciation of the British contributions to the development and application of radar in war. That generous cordiality has always characterized opinion at the Massachusetts Institute of Technology through all the variations of emphasis found elsewhere in discussions on radar history. It may be suggested that the Radiation Laboratory view is most happily enshrined in the emblem adorning the cover and the title-page of each volume in this impressive and satisfying series. The emblem shows the picture of a characteristic and cherished part of New England, the Cape Cod area, displayed on what even a Scottish reviewer may allow himself to describe as one product of Old England, the Plan Position Indicator, all surrounded, enshrined and defended by another product which its Australian-born inspirer would also gladly admit as a product of Old England, the anode of a resonant cavity magnetron. And integrally knit into this symbol of American-British interdependence in progress is the name of the great institution of which all British radar workers are as justly proud as are the American, the "Radiation Laboratory M.I.T., Cambridge, Mass., 1940–1945".

The book has few—remarkably few—errors; they will not mislead, and they will be corrected in the second edition which will certainly be demanded; they are negligible brush marks on a brilliantly successful piece of co-operative authorship. We join with the distinguished leader and inspirer of the Radiation Laboratory, Dr. L. A. Du Bridge, in the sense of his foreword: "to all those who contributed in any way to this great cooperative development enterprise, both in this country and in England, these volumes are dedicated". The monument is worthy of those to whom it is dedicated—and they were a great army of great men.

ROBERT WATSON-WATT

LANDSCAPE ARCHITECTURE

Land and Landscape

By Brenda Colvin. Pp. xii+266+106 plates. (London: John Murray, 1948.) 21*s*. net.

THE scenery of a long-settled country such as Britain is the result of the action and interaction of several factors. The background is provided by the relief and drainage of the land, the natural and semi-natural vegetation; the broad aspect is the result of economic use in the production of food and raw materials; but in detail the scenery is the result of man's conscious activities in the lay-out of his homes and their surroundings.

The term 'landscape architecture' is now commonly applied to work which is at once a science and an art. In planning a garden, small or large, still more in planning such an extensive area as an estate, the landscape architect requires to know and understand the scientific laws which have determined the surface form of the site and its vegetation cover before he can introduce those elements of design in which he uses living plants in order to obtain the desired effect. While it may be true that the formal garden never obtained quite the vogue in Britain which it had on the Continent, Britain abounds in mature examples of the work of landscape architects, especially those who laid out the great estates with their avenues of trees and their vistas, and which we associate particularly with the mansions built in the later part of the eighteenth century. Many of these carefully planned estates are to-day jealously guarded as part of our national heritage. Among the examples included in the album of photographs of Miss Colvin's volume we notice Blenheim and Chatsworth, but she does not forget to remind us that beech clumps on the chalk, such as Wittenham, or the informal landscape setting of Dinton House are also examples of landscape architecture, and she further reminds us that in detail the rock garden or the peculiarly English art of topiary must also be included.

Miss Colvin's book treats of a subject which it is extraordinarily difficult to expound, since it needs the clear understanding of the scientific principles involved on one hand and a balanced assessment of the æsthetic results on the other. Fashions change as much in landscape architecture as in architecture itself. Yet without attempting to decide between one style and another, there is at least a partial agreement on what constitutes 'good manners' in the treatment of landscape as there is in architecture.

In reading Miss Colvin's book one feels that behind a welter of words she is attempting to convey to the reader a philosophy which should underly any work of execution. One can learn much from having one's thoughts directed to some of the many examples she illustrates and describes; but the scientific reader will feel that she has failed to appreciate the meaning and influence of the natural laws which must govern the work of the landscape architect, and he is likely to show only impatience at what he may call a sentimental and subjective approach.

The book deserves the credit of being a pioneer in a difficult field. One would like to see a future development along the lines of a more adequate treatment of the scientific principles involved.

L. Dudley Stamp

RESEARCH ON MANAGEMENT

The Board of Directors and Business Management

By Melvin T. Copeland and Asst. Prof. Andrew R. Towl. Pp. xiii + 202. (Boston, Mass.: Harvard University, Division of Research, Graduate School of Business Administration, 1947.) 3.25 dollars.

In view of the widespread official and public interest in management as an important contributor to the solution of contemporary economic problems, it is to be regretted that so little has hitherto been done to ensure that the practice of management should be adequately supported by research. The controversy whether 'management' is a science or an art is largely academic and many people find it idle. Whatever its character, knowledge of the principles and methods of management, and improvements in its practice, can be obtained only from the collation and interpretation of experience, supplemented by systematic research. This is the approach customarily pursued in the natural sciences, and its value to the social sciences in general and to management in particular is more readily recognized in the United States than in Great Britain.

Copeland and Towl's book is evidence of the readiness of American universities and business corporations to collaborate in the conduct of research. It is a report on a research project; not one that has been carried out in an academic setting in terms of pure theory, but a practical investigation of certain aspects of higher management conducted in the setting of real life. The study starts from recognition of the fact that "a business corporation is inherently a social undertaking, in which several groups and divers personalities are assembled to work together to their mutual economic advantage". Among such groups is the board of directors, the group charged with responsibility for the formulation of policy and for the overall direction of the activities of the enterprise.

The different legal framework of American and British industry necessarily entails certain differences in the position and outlook of directors, but in the main the study resulting from this research is as pertinent and as valuable to British conditions as to those on the other side of the Atlantic. It can be briefly described as a review of most aspects of the functions of the board of directors, and of their attitude to their duties. It brings out clearly their primary responsibility for the formulation of policy, and stresses the corporate character of the board. The difference between a director as such and an executive in the organisation is also well brought out, and special attention is paid in later chapters to correcting misconceptions, as well as unfolding the 'unpleasant' tasks within the director's domain. So far as British conditions are concerned, the two common misconceptions of a director holding executive functions, and of a board being the gathering point for big names, are clearly diagnosed.

The authors round off their study by a chapter entitled "Some Questions which a Director may well ask himself". This is a factual list revealing the extent to which the research project was bedded in the actual practice of directors at work in a variety of industrial organisations.

The book can be safely recommended as a valuable contribution to literature, of value to the practising director, to the younger senior executive who has aspirations to the board, and even to those who are studying management as a matter of interest rather than preparing themselves at the moment for its higher levels. Perhaps the reviewer's only regret is that this particular study has come from American sources rather than British.

E. F. L. Brech

HUMOUR AND HUMANISM IN CHEMISTRY

Humour and Humanism in Chemistry

By Prof. John Read. Pp. xxiii+388+47 plates. (London: G. Bell and Sons, Ltd., 1947.) 21*s.* net.

As the author points out in his preface, "Humour and Humanism in Chemistry" is divided into three sections, the first two being approximately equal in length and dealing with alchemy and "chymistry", which the author defines as the transition from alchemy to chemistry, respectively. The last section deals with the chemistry of the late eighteenth and nineteenth centuries.

The first five chapters, which are concerned with alchemy, may be considered as an appendix to Prof. Read's "Prelude to Chemistry"; and they contain further interesting details and some expansion of matters already touched upon in the earlier work. There has been a tendency to ridicule alchemy and the alchemists; but however misguided some of them may have been, there is no doubt that important empirical discoveries were made by them, and they form a vital link in the chain of development by which chemistry graduated from an art to a science. The author shows understanding and sensitivity when dealing with these early workers.

The next two chapters (6 and 7) deal with such seventeenth- and eighteenth-century chemists as Jean Beguin, William Davisson, Johan Glauber, Nicolas Le Febure, Christopher Glaser, Nicolas Lemery and Herman Boerhaave. Prof. Read gives an account of the life and personality of each of these "chymical artists" and then details their main contributions to the literature of chemistry, with an analysis of the contents and relative importance of the works in question. This section of the book is particularly interesting, and is valuable because it stresses an important period in the development from alchemy to chemistry and shows how this development can be traced in the text-books written by these men.

The third and largest section of the book contains a wealth of interesting information but suffers somewhat from being disjointed. It opens with an account of Joseph Black's contribution to chemistry, and passing by way of Madame Marcet and her oft-reprinted text-book, leads up to a description of nineteenth century student life in the laboratories of the great masters Liebig, Bayer and Werner at Giessen, Munich and Zurich. A sympathetic evaluation of Sir William Pope's work and a good account of the man himself is followed by a chapter on Australia, dealing largely with the various eucalyptus trees indigenous to that country and the chemistry of the essential oils obtained from them. Finally comes an entertaining flight of fancy in the form of a "Chemic Drama in One Act".

The book, written in Prof. Read's customary charming style, is well produced and lavishly illustrated. DENIS I. DUVEEN

BIOCHEMISTRY IN PROGRESS

Annual Review of Biochemistry

J. Murray Luck, Editor; Hubert S. Loring, Associate Editor; Gordon Mackinney, Associate Editor. Vol. 16. Pp. xi+740. (Stanford University P.O.: Annual Reviews, Inc.; London: H. K. Lewis and Co., Ltd., 1947.) n.p.

THIS series of volumes continues to need no stimulus to its sales; all biochemists buy it or see it, or ought to. For the most part, as in previous years, the review for 1947 proceeds along familiar lines, with articles on biological oxidations, the chemistry and metabolism of the major foodstuffs, mineral metabolism, vitamins, hormones, and so on. But the editors always take care to vary the staple diet with something uncommon, and this year the 'bakemeats' include choline, anti-oxidants, animal biochromes (pigments to most of us, and why not ?), folic acid, anti-malarial drugs, and marine bacteriology. There is thus no lack of variety in subject-matter, which is treated throughout in the critical manner that reviewing of this kind demands, but does not always get.

Limitation of space does not allow the majority of the reviewers to go beyond their set task, that of discussing all the published work which has appeared since the last "Review"; all the more welcome, therefore, is an article on the use of isotopes in biochemical research, in which the snags of some methods, and the advantages of others, are freely and frankly canvassed on a platform of recent experiment, to the great profit of any reader who does not happen to be an expert in this field. It is to be hoped that this article is not the last of its kind.

The standard of the "Review", both in reporting and editing, is now so high that considerable suggestions for improvement are scarcely possible. But perhaps the editors might care to consider one small item. The bibliography attached to each article is so very useful to anybody wanting a quick conspectus of the subject that alphabetical arrangement of the authors would be an advantage. For the "Review" is not ephemeral, to be laid aside when the novelty of the contents has worn off; the back numbers are consulted by writers of books, papers and lectures, and much time can be consumed in searching through two hundred names for a single reference. It is true that some may prefer a bibliography to be arranged in the order of appearance of the references in the text, and for any but works of reference this system has much to commend it. But the "Review" is a work of reference. Already some of the articles have bibliographies alphabetically arranged; if some, why not all ? Doubtless the point has been made before, and anyhow it must not be allowed to stand between editors and reviewers and our thanks.

LOCAL GOVERNMENT AND THE CITIZEN

Local Government

By Sir A. S. MacNalty. (Home Study Books.) Pp. x+222. (London: Methuen and Co., Ltd., 1948.) 4*s*. 6*d*. net.

IN the new series of Home Study Books designed, under the general editorship of Dr. B. Ifor Evans, to cover "the most significant aspects of modern thought and investigation", two major considerations may be held to justify the inclusion of "Local Government" among the first seven titles: the close relationship between local government activity and the daily life of the citizen, and the negative attitude of a large proportion of the community towards the management of local affairs. Written with the view of assisting "men and women who are interested in the subject and who may be inclined, either as members or officials of local authorities, to devote their gifts to this important branch of national work for the common weal", this volume carries the insistent message that the effective co-operation of the private citizen is vital to progressive administration at local government level.

Since the book was written, developments have already taken place in the system of local government, and far-reaching changes are, of course, impending, such as those foreshadowed in the recently published second annual report of the Local Government Boundary Commission. The trend of such developments is discussed in a short final section on the future of local government, but the author's major purpose is to provide a historical background against which change may be seen in true perspective. The treatment, though authoritative, is not intended to be exhaustive, and since the book is "neither a textbook nor a legal treatise" the author delivers his own views on a number of live issues. He can fairly claim to have provided a comprehensive survey of the growth, structure and functions of local government, and the serious student will certainly want to add this book to his collection. It will perhaps be particularly valued for the special interest of the section on public health, in which the author's own experience speaks most clearly.

One curious omission may limit the book's appeal. Not a single chart, diagram or other form of graphic representation is used, although the subject so obviously lends itself to treatment of this kind. The average man or woman has grown to expect such aids, and the author who neglects to employ them when addressing the general reader places himself at an initial disadvantage. ERIC LOWE

The Atom

By Sir George Thomson. (Home University Library of Modern Knowledge, 145.) Third edition. Pp. viii + 196. (London: Oxford University Press, 1947.) 5*s*. net.

THIS is neither a text-book nor a 'popular' work, but a book of genuine educational value, in which present knowledge of atomic and nuclear physics is simply but clearly set forth, backed by the historical perspective of earlier ideas, and looking forward to the resolution of present difficulties by further experimental and theoretical development of the subject.

The writing of such a book demands nice judgment and strong determination to hold the balance between facts and theories, and to give no more than proper prominence to those parts of the subject that catch the imagination of the amateur. Sir George Thomson, as in previous editions of the book, has done this admirably and has given, in eighteen short chapters, a remarkably complete outline of modern knowledge of atoms and the electrons and nuclei that are their constituent parts. He never forgets that atoms are fundamental to chemistry as well as to physics, and the chapters on crystal structure, "The Atom in Chemistry" and "The Electron in Chemistry", are among the best in the book.

"The Atom", though quite an elementary book, deserves and indeed demands careful reading. Like the others in this series, it is meant for those who are prepared to think as well as to read. The thoughtful reader will not be satisfied with all the explanations of atomic phenomena that are offered; that is as it should be, for there are plenty of unsatisfying features in current theories. Sir George himself does not hesitate, on occasion, to envisage the overthrow of the views he is expounding; for example, he ends his discussion of the inherent limitations of physical measurement by speculating on "a probe more delicate than an electron", immune from its wave-like properties that he himself has done so much to establish and to use.

Radio Data Charts

A Series of Forty-four Abacs providing most of the Essential Data required in Receiver Design. By Dr. R. T. Beatty. Revised by J. McG. Sowerby. Fourth edition, second impression. Pp. 93. (London: Iliffe and Sons, Ltd., 1947.) 7*s*. 6*d*. net.

THESE charts present in nomogram form the solution to many of the problems met with in the design of radio receivers and similar apparatus. The explanatory text accompanying each chart is brief but clear, and not only gives the formula upon which the chart is based but also provides a general background to the problem. The method of use of each chart is fully explained by means of a key and is illustrated by examples.

In this fourth edition five new charts have been added. One enables the frequency response of single tuned and band-pass circuits to be determined; another gives the coupling coefficient of intermediate frequency transformers; and a third the resonant impedance of a quarter-wave line. The other two are concerned with the design of resistance-coupled amplifiers. Of the remaining charts, five cover the interrelation between inductance, capacity and frequency in resonant circuits over a wide range of values and another group deals with the design of radio-frequency coils, including the effect of screening cans. Assistance in the design of mains transformers and chokes, output transformers, transmission lines and resistance attenuators is also provided. Data on the D.C. resistance of wires, the power dissipated by a resistance and the reactance of coils and condensers, together with scales for the conversion of frequency to wave-length and ratio to decibels, complete this comprehensive collection of 'abacs'.

The main features of this volume which commend it to the radio engineer are the ease and speed with which design problems can be solved and the way in which the effect of changes in the values of the parameters involved can be readily determined.

Modern Magnetism

By Prof. L. F. Bates. Second edition, revised and enlarged. Pp. xi+440. (Cambridge: At the University Press, 1948.) 25*s*. net.

BATES'S "Modern Magnetism", first published in 1939, is widely appreciated as a general survey in which adequate attention is given to the experimental side. In preparing a second edition, the author's aim was that it should be reasonably up to date. Unfortunately, "the difficulties of the times made large-scale alterations of the existing pages impracticable", and the bulk of the new material, mostly on work published since 1938, is collected in six additional chapters, occupying about a hundred pages. These chapters deal with a wide variety of topics falling under the general headings of hysteresis, ferromagnetic substances, weakly magnetic substances, radiofrequency spectroscopy, adiabatic demagnetization, and paramagnetic absorption and dispersion. In view of the author's notable contributions in some of these fields, particular interest is attached to his presentation of cognate work; and the chapter on radiofrequency spectroscopy provides almost the only recent short survey of the elegant techniques applied in determining nuclear moments. The treatment in the new chapters is, no doubt, deliberately, somewhat uncritical; and the 'adding on' of the miscellaneous new material inevitably leads to some lack of coherence in the book. It is much to be hoped that conditions will later enable the author to reshape the book into an artistic whole. For the present, however, many readers will be most grateful to the author for collecting together so much interesting information about recent work in magnetism.

E. C. S.

The Romance of Rhodesia

Being the Impressions of a Sight-seeing Tour to Southern and Northern Rhodesia *via* Seychelles, Mombasa, Zanzibar and Dar-es-Salaam. By Ardaser Sorabjee N. Wadia. Pp. xiv+146+16 plates. (London: J. M. Dent and Sons, Ltd., 1947.) 21*s*. net.

MR. WADIA'S ready pen has this time been turned to describe a tourist trip to Rhodesia that was made before the War. He departed rarely from the conventional tourist route, and his brief sketch contains little that is new in factual information. Mr. Wadia touches frankly, however, on many of the problems that Rhodesia and other parts of Africa have to face. Thus he has reflexions on racial discrimination, the colour problem, the scope of missionary endeavour, and especially of the problem of Indians in South Africa. Generally he is critical of existing relations between races, but supports British rule. His criticisms are worthy of attention. The book is beautifully illustrated.

SIGNIFICANCE OF NUCLEAR CHANGE IN DIFFERENTIATION

By Dr. K. MATHER
John Innes Horticultural Institution, Merton

IN the process of differentiation, cells derived from a common ancestral cell take on different, though mutually adjusted, forms and functions. Some determinants must therefore change during this process in either the cytoplasm or the nucleus, or, of course, both. The genetical problem of differentiation is to discover what the properties of these determinants are, and how they are related to those other determinants, the genes, the permanency of which we recognize by their transmission from generation to generation in sexual reproduction.

There is a growing body of evidence that differentiation is at times, though by no means always, accompanied by changes in the nucleus. These changes appear to be of three main kinds: changes of elimination, replication and manifestation.

Changes of elimination involve specific whole chromosomes or specific parts of chromosomes, in which latter case the process is more commonly called diminution. Elimination is a rare occurrence, most cases being known in the Diptera[1]. In *Ascaris*, where the process is properly diminution, it affects every chromosome at the second to fifth cleavage divisions in those cells ancestral to the soma, the cells of the germ line showing no change. In *Miastor* only whole chromosomes are eliminated, 36 disappearing out of 48 from the somatic line at the third and fourth cleavages in females, and 42 out of the 48 in males[2]. Other Cecidomydæ behave in essentially the same way[3]. There is a possibility that this change in the Cecidomydæ is only one of reducing a polyploid nucleus to a diploid or haploid condition, so being unspecific for members of the basic complement. In *Sciara*, as in the Cecidomydæ, the elimination again differs according to whether the individual will become male or female; but it goes on over a longer period of development, and at least one chromosome, and possibly more, is eliminated in the germ track. In this fly, too, the members of the basic set are differentially eliminated, and genetical evidence shows further that even homologous chromosomes behave differently, those of paternal origin being eliminated while maternal chromosomes remain. One case of elimination is known in plants, supernumerary chromosomes vanishing from the nuclei of what we may call the root line in *Sorghum*, but remaining in at least part of the shoot line, from which, of course, the reproductive cells develop[4].

It thus appears that elimination essentially brings about a difference between the nuclei of germ line and somatic line, the former obviously retaining the full complement of chromosomes, except in *Sciara*, where the loss in the germ line is offset by later and equally remarkable multiplication. In no case is there evidence that the nuclei of the various somatic tissues characteristically have different chromosome complements as a result of further elimination. The precise function of the eliminated chromosomes or chromosome parts is not clear, but in *Ascaris*, and probably in *Sorghum* too, they are heterochromatic[5], and hence presumably lacking in major genes.

Changes of replication are in nearly every case non-specific, all the chromosomes showing the change equally. The chromosomes divide more often than does the nucleus. This leads to polyploid nuclei where the centromeres divide with the chromosomes, and to polytene nuclei, the chromosomes of which have multiple strands as in the salivary glands and other tissues of *Drosophila*, where the centromeres do not divide. The difference between polyploidy and polyteny is thus a minor one from our present point of view, and the two are conveniently pooled under one name. Two such names appear to be in use, and of them endopolyploidy is preferable to polysomaty, for the latter might easily become confused with the term polysomy, which has an entirely different meaning. Sometimes, also, the nucleus may divide without the cell doing so, so giving a third variant, the multinucleate cell or coenocyte[6].

Replication seems commonly to mark the end of active cell division and the onset of differentiation, and White[1] states that the various tissues of insects all have their characteristic degrees of endopolyploidy, some being mosaics of different multiples of the original number of chromosomes. He regards it as likely that the phenomenon is widespread in other animal groups. It is also fairly common in plants, particularly, it would appear, in cortical tissues[7,8]. Here again mosaicism is frequent, and one of its genetical consequences is the production of a proportion of tetraploid shoots among the diploids regenerated from callus originating in the cortex of decapitated tomato stems. The reverse of replication seems also to occur, though less commonly. Apart from the possibility that elimination in the Cecidomydæ is a change of this kind, equal reduction, by what must be tantamount to somatic meiosis, has been recorded in *Culex*[9] and in onion and barley roots, especially in the latter case after treatment with growth substances[8].

We have already noticed that changes of replication are generally non-specific or balanced; but in a few cases replication is confined to specific chromosomes. The so-called X doubles itself once oftener than any other chromosome at meiosis in normal male *Sciara*, and the X of *Drosophila* does the same when the males are carrying the 'sex-ratio' super-gene. In *Sciara* this behaviour compensates for an elimination early in the germ track, and in sex-ratio *Drosophila* the Y is eliminated simultaneously[10]. This relation of specific or unequal replication and elimination may well be significant in animals. It has been claimed that similar replication also occurs in the root tissues of certain orchids where no elimination is known, but the evidence for this behaviour cannot be regarded as final[11].

Changes of manifestation strictly involve no alteration in the number or balance of the genes. A typical example is afforded by the different rates of condensation of the chromosomes in the two daughter nuclei produced by the first division in pollen grains. This difference depends in no way on a genetic inequality between the nuclei, for sometimes by either accident or treatment the spindle is formed 90° out of its true line and then the nuclei condense at equal rates. A cytoplasmic gradient must be the cause of the difference[12]. The difference between two daughter nuclei, one destined to divide again and the other not, at the margin of a meristematic region also marks a change of manifestation, as must many differences of chromosome size and contraction. Some of these changes, such as that concerning future division, must affect the chromosomes equally, but in others heterochromatin and euchromatin may behave differently.

Changes of manifestation, though not themselves involving changes of genic number, may be associated with other changes that do. Thus the daughter nucleus, the fate of which it is to divide no further, may undergo a change of replication. Also the chromosome fragmentation which immediately precedes diminution in *Ascaris* would seem properly to be regarded as a change of manifestation, for of itself it involves no change in the genes (apart from a possible change in position effect), but only a partial breakdown of their linear organisation. It, too, seems to depend on a cytoplasmic gradient like the difference between the pollen grain nuclei[13].

What is the significance of these various changes for our understanding of differentiation ? To answer this question we must see that it consists of two parts, and ask not merely what are the effects of the changes, but also what are their causes.

On the various occasions when it has been recorded that nuclear change accompanies differentiation, there has usually been a suggestion, implicit in the presentation rather than explicit in the statement, that the process of differentiation was an effect of the change in the nucleus. This suggested relation is seldom capable of the direct test of experimental breeding, for the differentiated cells and tissues cannot usually be induced each to regenerate an individual organism sufficiently complete for its genetic constitution to be ascertained. Even in plants, where asexual propagation is possible from roots, shoots and even leaves, regeneration is most often from complexes of different tissues. Nevertheless, when all the myriad examples of asexual propagation afforded by everyday horticulture are taken into account, the conclusion seems inescapable that in plants, with the exception of occasional polyploidy, the cells and tissues are genetically alike. Nor can polyploidy, nor any form of endopolyploidy, be regarded as a type of change intrinsically likely to produce differentiation. Polyploidy is one of the most common differences between individuals in plants, and is also known in a number of animals like flies and newts. Apart from the upsets of sexual development predictable from their detailed chromosome constitutions, the polyploid individuals have a normal structure with all the customary tissues developing and co-operating in the customary fashion. Indeed, it often requires a practised eye to distinguish diploid and polyploid by inspection. Whatever their other significance, changes of replication can scarcely be taken as a cause of differentiation.

The case against changes of elimination is a little different. Where they occur, they are commonly associated with a major dichotomy in the fates of the cells, to give soma as opposed to germ line, or root as against shoot. The soma, or the shoot, has, however, itself a host of differentiated tissues associated with no further elimination. Also, as we have seen, elimination is a rare phenomenon, and its counterpart, unequal replication, even rarer. Thus even if elimination (or unequal replication) should in truth cause the differentiation with which it is associated, another and more general cause must still underlie most tissue differences. Furthermore, genetical experience shows that, like polyploidy, monosomy and polysomy in a wide range of plants and animals can characterize whole individuals, all of the tissues of which differentiate and co-operate sufficiently well for viability (though admittedly with rare exceptions all monosomics and polysomics are somewhat abnormal in form and may even be inviable where the genic unbalance is too great). In these species simple elimination could scarcely account for differentiation.

It might, of course, be argued that these observations should be given little weight, that physical elimination or unequal replication as a cause of differentiation is a phenomenon of individual genes rather than of whole chromosomes or of large segments of chromosomes. To do so would be to postulate a process for which there is no independent genetical or cytological evidence. Nor could it give a complete account of the process, for we should still be faced with the problem of why the genes were eliminated or multiplied differentially just at the appropriate times. Indeed, no hypothesis which makes differentiation the outcome of elimination or multiplication, whether balanced or unbalanced, affecting chromosomes, segments or individual genes, can be regarded as satisfactory, for it leaves unexplained the cause of the nuclear change itself. In adopting such a view we should merely replace one genetical problem of differentiation by another. The answer to our question must be sought in another direction, one to which changes of manifestation point the way.

We now have a wide range of evidence to show that the behaviour of a cell depends immediately not on its nucleus, but on its cytoplasm, which, though ultimately determined by an associated nucleus, may be acting in a manner reflecting the nucleus of a past association rather than that of the present. This persistence of the effect of a nucleus in the cytoplasm shows us that the nucleus, though remaining constant in its genetic content, can have a changing effective action. It is constantly acting on and altering the cytoplasm, so that the circumstances in which it finds itself are altering and with them the future effect of its action[13,14].

The nucleus itself affords a sensitive test of the constitution of the cytoplasm, so sensitive that it enables us to detect differentiation within the cell, as we have already seen in pollen grains. Indeed, we have several lines of evidence showing us how the fate of the nucleus depends on the cytoplasm. The timing of nuclear processes in great blocks of tissues, like the spermatogonia of animals, must be brought about through the cytoplasmic connexions of the cells. Pairs of pollen grains with nuclei showing complementary unbalance (5 and 7 chromosomes in place of the normal 6 in *Rhœo*[15], and 6 and 8 or 5 and 9, etc., in place of the normal 7 in *Uvularia*[16]) can live and their nuclei divide so long as they have cytoplasmic connexions through which the products of locally unbalanced gene action can be evened out ; but they die when the cytoplasmic connexion

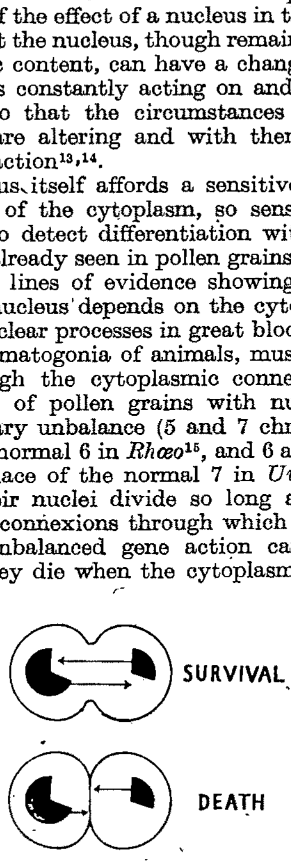

Fig. 1. PAIRS OF POLLEN GRAINS THE NUCLEI OF WHICH SHOW COMPLEMENTARY UNBALANCE, ONE CARRYING IN DUPLICATE THE CHROMOSOMES FOR WHICH THE OTHER IS DEFICIENT, CAN SURVIVE AND THE NUCLEI CONTINUE TO DIVIDE PROVIDED THAT WALL FORMATION IS NOT COMPLETE SO THAT THEY ENJOY A CYTOPLASMIC CONNEXION. WITH COMPLETE WALL FORMATION AND LOSS OF THE CYTOPLASMIC CONNEXION THEY DIE

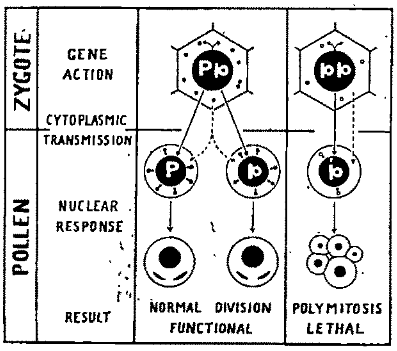

Fig. 2. POLYMITOSIS OF THE NUCLEI IN MAIZE POLLEN GRAINS DEPENDS ON THE ACTION OF A RECESSIVE GENE IN THE SPOROPHYTE. THE NORMAL OR POLYMITOTIC BEHAVIOUR OF THE POLLEN GRAIN'S NUCLEUS DEPENDS NOT ON THE GENE IT CARRIES, BUT ON THE CYTOPLASM THE POLLEN GRAIN INHERITED FROM ITS PARENT ZYGOTE, WHERE THE CYTOPLASM'S CONSTITUTION WAS DETERMINED BY THE ACTION OF THE DIPLOID NUCLEUS WITH WHICH IT WAS THEN ASSOCIATED

is lost (Fig. 1). Furthermore, the cytoplasm can, in its regulation of nuclear processes, reflect the action of a gene no longer contained in the nucleus. This we can see in Beadle's[17] polymitotic maize, where plants homozygous for the gene produce pollen grains all the nuclei of which undergo premature supernumerary divisions. The chromosomes do not show corresponding divisions, so that the nuclei come to contain reduced numbers of chromosomes, some, in fact, having only one. The result is a group of pseudo pollen grains which all die. Plants heterozygous for the gene must produce two genetically different kinds of pollen, one of which will be like the lethal polymitotic pollen borne on the homozygous plants. But none of this pollen shows polymitotic behaviour. Thus polymitosis is like incompatibility in heterostyled plants[18]. The nuclei of the pollen grains do not determine their own fate. Their behaviour, normal or polymitotic, is determined by the cytoplasm transmitted from the parent zygote, where, however, its constitution was determined by the diploid nucleus with which it was then associated (Fig. 2). This principle even applies to the process of elimination, for the loss of one or two X's, to give females or males, depends in *Sciara* on the genic constitution of the mother, from whom the cytoplasm must have been derived even though the determining gene may not have been passed on to the individual showing the elimination.

Changes of manifestation, which have no direct effect on genic constitution, and so can never of themselves cause differentiation, thus show us how the cytoplasm of one cell can be differentiated so that the fates of the daughter cells will depend, not on which daughter nucleus each obtains (for these will be alike), but on which part of the cytoplasm each inherits. By the aid of these changes we can see how the continuation and adjustment of the processes of nuclear division depend on the cytoplasm, and hence how endopolyploidy can be a response to the condition of the cytoplasm. We can even see how elimination is but another example of cytoplasmic control. Finally, we can see how the cytoplasm, in determining these changes of the nucleus, is itself reflecting the past action of that same nucleus or of some other nucleus with which it has been earlier associated.

All these nuclear changes can be interpreted as responses to an accomplished differentiation of the cytoplasm, and many of them, indeed, demand such an interpretation. The nuclear change is but a consequence of the earlier action of the unchanged nucleus. Differentiation is neither generally nor necessarily dependent on the physical elimination or unequal multiplication of the genes and chromosomes to produce what would be seen in a complete individual as a genetic unbalance; it depends on the physiological reduction or enhancement of gene action by the constitution of a cytoplasm itself reflecting the earlier action of these same genes. The nuclear changes we see are special effects rather than general causes of differentiation. They are special examples of the general process to which all differentiation must be referred.

As an organ the nucleus, like other organs, is part of the phenotype and its behaviour is under the control of its own genes acting in their customary fashion through the cytoplasm. It is true that the phenotypic changes of the nucleus may have a special significance in that some of them might mean changes of the genotype. But this should not blind us to the fact that, even though these secondary changes of genotype may have an adaptive significance in some special cases like *Sciara*, they are nevertheless still secondary. They still depend on a previous change of the nucleus acting as phenotype to the genotype it carried in its earlier and unchanged form. Only if we are careful to distinguish between these two aspects of the nucleus, the recently understood phenotypic as well as the long appreciated genotypic, can we hope to assess the true significance of nuclear change in differentiation.

BIOLOGICAL ASPECTS OF WATER POLLUTION

AT a meeting of the Association of Applied Biologists on March 22, five papers were contributed to a symposium on "Biological Aspects of Water Pollution".

Dr. B. A. Southgate, who introduced the subject, said that it includes the treatment of sewage and industrial wastes, the effect of effluents on natural waters to which they might be discharged, and the treatment of polluted water to render it fit for drinking or for other use.

The constituents of domestic sewage are mainly derived from fæces, urine, paper, soap, and vegetable and animal matter. In towns, these are usually augmented by the constituents of gas works liquor, which contains thiocyanate, phenols, ammonia and sulphide, and of such trade wastes as are associated with industries peculiar to the town. Effluents from manufacturing processes may contain a variety of substances in solution, such as metals or complex cyanides from the metal and electro-plating industries, or plant extracts from such operations as the retting of flax or the washing of vegetables before canning or drying. Colloidal and suspended material is derived from a number of sources, including soil and plant debris.

It is important for several reasons that such wastes should be adequately treated before discharge to surface waters, which are the chief source of domestic water supplies. A high standard of quality is frequently necessary, too, for an industrial water supply, and cases are known in which an industry has had to be moved to a fresh location because the river from which its supply was drawn had become polluted. The purity of rivers is important also to agriculture and to inland fisheries.

In the biological treatment of sewage, purification is effected by interaction of the sewage with the biological film of a percolating filter or with flocs of activated sludge. In both types of treatment bacteria, fungi and protozoa play an essential part, and in the percolating filter the scouring action of worms and fly larvæ is also necessary. Certain types of industrial waste are amenable to separate biological treatment, under anaerobic or aerobic conditions, and some can be so treated that they can be re-used in industrial processes. Inorganic substances such as chromates and cyanides, if present in industrial wastes in appreciable amounts, often have to be removed by chemical means before the effluents are discharged to streams or to sewers.

Dr. L. A. Allen, who dealt with some microbiological problems of the treatment of sewage and trade wastes, said that microscopic examination of the biological film from a percolating filter, or of an activated sludge floc, reveals a mass of bacteria and fungal hyphæ, embedded in gelatinous or mucoid material, together with smaller numbers of protozoa. This material presents to the sewage with which it comes into contact a large and active biological surface which adsorbs a large part of the colloidal and dissolved substances. Microbial metabolism then results partly in oxidation of the adsorbed material and partly in its conversion to fresh cell substance, leading to an increase in the quantity of film or sludge.

Even under most favourable conditions, the effluent discharged to a river from a sewage treatment plant may contain several hundred coliform bacteria per ml. It has been observed, however, that in the course of a few miles natural processes in the river frequently reduce the fæcal organisms to a small fraction of the number discharged. Such an effluent cannot be treated with chlorine to destroy bacteria without first considering the possible effects on the life of aquatic organisms. With some effluents, for example, a dose of chlorine much smaller than the chlorine demand is sufficient to make the liquid highly toxic to fish.

Three examples of trade wastes were chosen to illustrate different types of microbiological problems.

Effluents from dairy premises are particularly liable to cause blocking of percolating filters, the high proportion of carbohydrate resulting in excessive growth of biological film. Investigation has shown that if this film, which consists largely of a tough mat of fungal mycelium, be subjected to starvation, the protoplasm becomes concentrated in certain cells of the mycelium, leaving others empty, thus weakening the mechanical strength of the fungal mat, which quickly disintegrates. In practice, this period of starvation is ensured by employing two filters in series, the effluent from the first filter being fed to the second filter. At suitable intervals the order of the filters is reversed. By this process—now known as alternating double filtration—it is possible to treat certain liquids at three or four times the normal rate.

Disposal of highly polluting waste liquors from the retting of flax has been avoided by subjecting the liquid to continuous aeration during the process of retting. Bacterial oxidation prevents the liquor from becoming acidic and foul-smelling, and reduces the content of organic matter, so that the liquid can be re-used for successive batches of flax.

In the manufacture of beet sugar, the practice of re-circulating the waste waters to diffusers in order to avoid discharging them leads to corrosion in the re-circulation system. Investigation has shown that this is due to formation of acid by thermophilic lactobacilli which can be prevented from growing by applying chlorine to the contents of the battery supply tank or by maintaining the re-circulation system at a sufficiently high temperature.

Mr. T. G. Tomlinson described the percolating filter as an artificial habitat in which both terrestrial and aquatic organisms are found in far greater abundance than in their natural surroundings. The types of fungi which predominate there are largely determined by the character of the liquid being treated. *Saprolegnium*, for example, is encouraged by domestic sewage and by waste waters from processing of food but is inhibited by the trade wastes from large towns; in filters treating the latter, it is usual to find instead two species of *Sepedonium*, characterized by tuberculate chlamydospores, accompanied by *Ascoidea rubescens*, which often produces large ovoid conidia. *Fusarium aqueductum* occupies a rather special place in the surface flora of percolating filters because its holdfast, prostate system of filaments enables it to cling firmly to the medium when washed by the jets of liquid from the distributor.

The population of protozoa shows a gradation throughout the depth of the filter. Polysaprobic zones at the surface contain *Opercularia*, *Paramecium caudatum*, *Colpidium*, and *Glaucoma*. In the mesosaprobic zones lower down are *Aspidisca costata*, *Euplotes*, and testaceous rhizopods; rotifers are found towards the bottom.

Of the Oligochæta, *Lumbricillus lineatus*, a small red worm possessing hæmoglobin, occurs universally in percolating filters throughout the whole year. The handicap of a long generation time and low fecundity is compensated by a low metabolic rate and a strongly gregarious habit.

Among the more numerous insects are two species of *Psychoda*, two of *Spaniotoma*, two of *Metriocnemus*, *Anisopus fenestralis*, *Anisopus collembola*, *Achorutes subviaticus*, and *Tomocerus minor*. The controlling factor in the balance of these species is the amount of film, which in turn depends on the rate at which sewage is applied to the filter. During the warmer months *Psychoda alternata*, with a life-cycle of four weeks at 15° C., and of two weeks at 21° C., is dominant. *Anisopus fenestralis* develops more slowly than *Psychoda*, requiring three months for completion of its life-cycle at 10° C., but its larvæ remain active at temperatures below 10° C., so that eggs laid in late autumn may give rise to a generation which matures slowly throughout the winter and emerges in the spring.

Dr. Ll. Lloyd, describing the part played by insects and worms in the disintegration of the biological film in a percolating filter, said that whereas in winter surface growth is usually much in evidence and the medium is slimy throughout the depth of the filter, in summer the same medium often appears perfectly clean. In general, depletion in the quantity of biological film has no effect on the efficiency of the filter.

The effect of film depletion is reflected in the behaviour of the flies, and a very good example is afforded by the study of species of *Psychoda* at Leeds. Here the number of *Ps. severini* reaches a peak in May but is small at any other time of the year. *Ps. alternata* shows a peak in June which is followed by a steady decline, and the sequence is then taken up by *Spaniotoma minima*, which builds up an enormous population in the autumn. If the supply of food is sufficient, all three species will breed abundantly from spring to autumn; curtailment of the food supply tends to restrict development, the species which predominates depending on factors which give it a seasonal advantage over its competitors. Introduction of midges (*Metriocnemus* species) introduces a complicating factor. Although essentially grazers on film, they take readily to a predatory habit and when present they tend to restrict the numbers of the three species of flies just mentioned.

There is also some evidence that food supply affects the size of flies. In the absence of other factors, size depends on temperature, wing-length increasing by about 2 per cent for each fall of 1° C. in later larval life. In fact, however, the steady increase due to this factor in the size of flies emerging from August onwards shows periodic interruptions which suggest the effect of shortage of food.

Mr. F. T. K. Pentelow said that the effects of pollution on fisheries may result from damage either to the fish themselves, to their spawn or spawning ground, or to their food. Conclusions from toxicity experiments are complicated by the fact that toxicity is greatly affected by the concentration of such substances as calcium in the diluting water, by the concentration of dissolved oxygen, and by the temperature. An idea of the toxicity of different substances is given by the following figures, which express, in parts per million, the concentrations found to be toxic to trout under average conditions: cyanide, 0·15; sulphide, 1·0; chlorine, 0·2; phenol, 9·0; sulphuric acid, 10·0; *para*-cresol, 6·0; 1.2.6 xylenol, 10·0; the toxicity, to sticklebacks, of copper is about 0·02 and of zinc about 0·3.

The mode of action of poisons varies widely. Cyanide, for example, destroys the enzyme responsible for transferring oxygen from the blood to the tissues, phenols and cresols appear to be nerve poisons, and heavy metals prevent respiration by coagulating the mucus over the body and gills. With some poisons the toxic action is reversible, affected fish recovering after transference to fresh water, but with other substances it is not. Thus, a shoal of fish subjected to the action of phenol from a temporary discharge of gas liquor might easily recover if the current carried them to a zone of cleaner water, but fish affected by discharge of chlorine or ammonia in similar circumstances would die. The behaviour of fish towards a particular substance is no criterion of its toxicity. They will, for example, keep strictly away from waters containing the less toxic zinc salts, but are so indifferent to the presence of the highly toxic copper salts that they are rapidly killed.

Bacterial oxidation of discharged organic matter results in depletion of oxygen in the river water. Though fish may not be actually asphyxiated until the oxygen content falls to between 0·1 and 0·2 part per 100,000, in practice it is frequently found that fish are absent from waters in which pollution has reduced the value to about 0·5 part per 100,000.

The effect of pollution on spawn and spawning grounds is almost unknown territory, but more is known about its effect on fish food. In general, pollution of streams by organic matter frequently results in replacement of the characteristic flora and fauna by other types, but without necessarily reducing the total quantity of material acceptable to fish as food. Pollution by inorganic substances is a very different matter. For example, discharge of copper wastes to a stream has been known to render it unable to support the life of trout, even in zones downstream where the concentration of copper is much too small to be directly toxic; this is because the copper has destroyed the animal life on which carnivorous fish like trout depend.

THE ROYAL ACADEMY, 1948

By Dr. A. TINDELL HOPWOOD
British Museum (Natural History)

SOCRATES once likened books to pictures because, "the creatures of the latter art stand before you as if they were alive, but if you ask them a question, they look very solemn and say not a word". To an argumentative old man the lack of response was deplorable; but to the pictures themselves, had they been sentient, it would assuredly have been the height of wisdom. Many a canvas would be covered with confusion, and mantled with blushes, were it suddenly to be faced by Socrates and to hear the dread question, "Why were you painted ?" Imagine the unease of the self-confessed pot-boiler, the tearful admission of the failures, and the venomous hatred of the shams. No, it is just as well that pictures cannot reply in words. On the other hand, our questions are not left entirely unanswered; but some degree of skill is needed to decipher the very solemn faces masking the replies.

Now, morally there is nothing wrong with an honest pot-boiler. A certain snobbish section of the public is only too ready to repeat hollow phrases about 'art for art's sake', without pausing to reflect that artists, like other men, must eat. Provided that the painter of a pot-boiler has the pride proper to a good craftsman, he plays a useful part in life, even though he does not produce a masterpiece. After all, and we may just as well admit it, none of the great masters of the past, not even Rembrandt or Turner, was consistently inspired; many a picture to which a famous name is attached is to be valued for its craftsmanship rather than for its genius. So let us praise honest craftsmanship wherever we find it, rather than indulge in unkind sneers at the unfortunate whose inspiration has forsaken him for a while.

Failures and shams are another matter; each reflects upon the character of its author. The failure exposed to public view argues a lack of that sensitivity which is necessary for the recognition that success has eluded one's efforts. As for the painters of shams, it can only be hoped that their spirits may meet with Socrates in the shades: that were punishment infinitely worse than the torment reserved by Dante for the hypocrites.

Why all this? Well, it's a dull Academy this year, and I do not like dull academies. Good ones are exhilarating, bad ones can be interesting; but dull ones are just dull. Perhaps the hanging is not quite up to standard, and the hanging can make or mar an exhibition. Indeed, the skill and knowledge needed to hang a single wall well, let alone a whole room, seldom receive the recognition which is their due. As a rule, visitors are so busy with the details that they spare no thought for the whole. On the other hand, every experienced gallery-goer has memories, either of good pictures spoiled by bad hanging, or of mediocre pictures vastly improved by good hanging.

Some may remember a certain north wall in one of the Academy's own rooms that was a masterpiece of the hanger's skill a few years ago; two pictures, which normally would have been pushed into a quiet corner, were put in the very centre of the wall, and their sophisticated crudity of colour allowed to lose itself among pictures of an entirely different type and key. The arrangement of that wall revealed the touch of a master; but this year it seems that some of the best pictures are overshadowed, perhaps outshone would be the better word, by the stronger colour of less meritorious neighbours.

The first thing to strike the eye as one ascends the staircase is a curious, whitish, skeletonized structure dominating the Central Hall; actually it is a ferro-concrete version of Bellerophon astride Pegasus, but it also serves to suggest that we begin with the sculpture for a change. Two portraits are of particular interest. One is "Sir Alexander Fleming, F.R.S.", by E. Roland Bevan, and the other "The Viscount Nuffield", by Maurice Lambert. This latter is remarkable for the skill with which the problem of combining originality of treatment with the conventions of formal statuary has been solved; as proof of the sculptor's versatility there is "Starbird" in the South Room. The Lecture Room contains many pleasant pieces; among them are several good figures of animals. "Hunting Leopard" and "Cheetah", both by Pamela Ascherson, "Friesian Bull" and "Complacent Cat", by Marjorie Drawbell, "Cat" by Richard Garbe, and "Falcon" by John M. Luxmore, are only a random selection.

The Lecture Room leads into Gallery IX, the black-and-white room, which contains four drawings of antelopes by Frank Dobson, those of the "Kenya Impala" and the "Black Buck" being particularly good. Barbara Greg's pen and wash drawing of "Adelaide Crescent, Hove", which hangs a few feet away, deserves a better place than it occupies at present. Her woodcut, "A Meeting of the Hell-fire Club", is less successful.

As a rule the Architectural Room contains smaller pictures by lesser lights; but this year there is an imposing array of academicians to keep them company and to spur them on to greater efforts. Here hang "The Blue Sitting Room, Trent Park" by Winston S. Churchill, and "Herrings and Lobster" by Edward le Bas, as well as "Kippers" by Robert H. Hurdle—a newcomer, I think—whose "Round Table: Still Life" in Gallery IV is one of the best pictures of its type in the exhibition.

Of the younger artists, as I judge them to be, Lionel Miskin (No. 30) and Kenneth Martin (No. 42) seemed to be the best in the first room, and Ernest Sandoe (No. 35) is better this year than last. In Gallery II "The Interval", by Jean Primrose, more than maintains the high level of her pictures last year; "Bannockburn", by Colum Gore-Booth, also deserves a word of praise.

Gallery III is, of course, the main room, and one does not expect many beginners to grace its walls; but two pictures by less well-known painters ought to attract favourable attention; they are "A Present from Provence", by Enid Solomon, and "The Bay", by Adrian Hill. Mr. Churchill's "Blenheim Tapestries" is not so satisfying as his "Goldfish Pool, Chartwell", in the previous room. In portraiture, Henry M. Carr vies with Sir Gerald Kelly, pitting his "F.-M. The Viscount Alexander of Tunis" against the latter's "Sir Malcolm Sargent": one feels that each was completely absorbed in his sitter.

Among paintings in other rooms are "The Fiddler", by Violeta Janes, and "Copying at the National Gallery", by Douglas Mays, both in Gallery V. Apparently this is the first time Miss Janes has exhibited, whereas Mr. Mays, who is 'on the line', made his first appearance last year.

The water-colours, in the South Rooms, are an attractive and varied display. Vivian Pitchforth and John Nash are a continuing inspiration to many, though few come anywhere near them in execution or content. Of the others, I particularly liked "Suffolk Landscape", by Rowland Suddaby, Dorothea Maclagan's flower pieces, "Haze Lifting, Newhaven", by Hadley Rowe, "Propeller Stacks, Deptford Creek", by Innes Meo, and "Cotswold Landscape", by Elizabeth Sorrell.

OBITUARIES

Dr. H. W. Richmond, F.R.S.

Herbert William Richmond, the eminent geometer, died of heart failure in the Evelyn Nursing Home, Cambridge, on April 22, at the age of eighty-four. At the time of his death he was senior fellow of King's College, Cambridge, where he had resided almost continuously for sixty-five years. The only substantial break in this long period of residence was during the First World War, from 1916 until 1919, when he worked at ballistics at Portsmouth with A. V. Hill and the late Sir Ralph Fowler; during this period he helped to make important contributions on the effects of winds on high-angle trajectories and the effects of spin on the motion of a shell. The last-mentioned work was done in conjunction with R. H. Fowler, E. G. Gallop and C. N. H. Lock; it was published in the *Philosophical Transactions of the Royal Society*, and afterwards became a classic. After the War he edited at Cambridge the confidential "Text-Book of Anti-Aircraft Gunnery", Vols. 1 and 2.

Richmond was born on July 17, 1863, at Tottenham (Middlesex), at Draper's College, of which his father, the Rev. Wm. Hall Richmond, was headmaster. He was educated at Merchant Taylors' School (1875–82), and went up to King's College, Cambridge, in 1882 with an Eton scholarship thrown open on this occasion. In 1885 he was Third Wrangler in Parts 1 and 2 of the Mathematical Tripos, and he was placed in Division I of Part 3 of the same Tripos six months later. He was elected a fellow of King's in 1888, and remained a fellow for the rest of his life. He was lecturer in mathematics at King's from 1891 until 1927, and University lecturer at Cambridge during 1901–19 and again during 1926–28. He was elected a fellow of the Royal Society in 1911. He was president of the London Mathematical Society for 1920–22, and he received the honorary degree of LL.D. from St. Andrews in 1923.

Richmond's mathematical interests lay chiefly in the fields of pure and algebraic geometry. He has left it on record that the side of geometry that appealed to him and fascinated him, in his undergraduate days and later, was the algebraic geometry of Steiner, Hesse, Cayley and Salmon—the geometry of cubic and quartic curves and surfaces worked out by methods of elementary algebra. This (he went on) was not exhausted, but was largely worked out, as he discovered when he went on to research, although a new field of research was opened up in geometry of four dimensions. Richmond's skill lay in the discovery of relations between apparently dissimilar groups of theorems, and his papers achieved much with notable economy of effort. He never failed to be interested in chains of theorems in plane geometry; but he also took pleasure in deducing theorems in the theory of numbers by geometrical methods. He was wont to consider the modern pure mathematician's restriction of interest to the *positive* integers as artificial and as reducing the geometrical implications of such theorems as Waring's. He continued his output of original work up to shortly before his death.

Richmond had a deep love for music—he devoted himself to this for a period after taking his degree. He also took a keen delight in all living creatures, and he was no mean naturalist. In his earlier days he went regularly to the Orkneys and Shetlands to photograph sea-birds and their nests. He had served on the Committee for Wicken Fen. But no bare record of his interests and achievements can do justice to the true qualities of the man. He had a rare genius for friendships with men of all generations, and in spite of his shyness he made a point of being helpful to men who came up from the lesser known schools without friends or influence. His modesty was terrific—that adjective alone fits. One recalls also his engaging humour, his humanity and his impatience with anything pretentious or shoddy. It was lovely to know him. His death robs Cambridge of a retiring but much-loved character.

E. A. MILNE

Prof. P. A. C. Dangeard

PIERRE AUGUSTIN CLEMENT DANGEARD was born at Ségrie-Vernie (Sarthe) on November 23, 1862. The son of a peasant stock, from which he doubtless inherited his individualism and determination, he entered l'Ecole Normale Primaire d'Alençon in 1878, becoming a school-teacher three years later. In 1883, his botanical aptitude having attracted the attention of Morière, then professor of botany at Caen, he was appointed demonstrator there, and lecturer in 1886. He moved to Poitiers in 1891, and was promoted professor in 1894. In 1908 he left Poitiers for Paris, where, in 1924, he succeeded G. Bonnier in the chair of general botany at the Sorbonne. He retired to the family property at Ségrie in 1944, and, after two years of troublesome illness, died there on November 10, 1947.

Dangeard was elected to the Academie des Sciences, Paris, in 1917. In 1931 the University of Cambridge conferred the honorary doctorate of science on him (family illness had prevented him from attending the Fifth Botanical Congress in 1930). The Linnean Society of London elected him a foreign member in 1935. Dangeard was awarded his doctorate by the Faculté des Sciences, Paris, for his "Recherches sur les organismes inférieurs" (1886), a contribution to botany which brought him the support of the algologist Bornet, and the Prix Desmazières (1887), and which laid down the main lines of many of the investigations which occupied him for the rest of his life. Developments and extensions brought further important publications (1896, 1903, 1904), on the cytology and sexuality of the fungi; these were recognized by the Grand Prix des Sciences Physiques de l'Institut de France. These contributions not only extended his own work, but they later generated a great volume of research by numerous workers all over the world on subjects which still claim the active attention of a number of botanists. Dangeard's demonstration of the nuclear fusions in young asci and basidia stands as a solid addition to our knowledge, though perhaps because investigations by other workers in the same field may have been over-valued, especially outside France, recognition was slow in coming to him.

In 1887 Dangeard began to issue *Le Botaniste*, a periodical supported from his own resources, which eventually ran to thirty-one volumes of some three hundred pages each, very many written by Dangeard himself. In the first issue, he explained that he had founded *Le Botaniste* so that he might have a means of publication which was wholly under his own control, in which he could express freely and defend adequately his own ideas, and in which he could assail freely any views which he deemed to be faulty. This explanation, and the contents of the periodical, illustrate the character of the man. He was extremely independent in his outlook, a tireless and accomplished observer, and a bold expositor of wide generalizations. With all that, and with a periodical completely his own, he was a fair controversialist. Throughout his life, Dangeard was greatly interested in those organisms which lie on the boundary between the plant and animal kingdoms, and in their relatives. He described a great number of new genera and species, he made detailed studies on the structure and physiology of the cell, and he put out a very clear exposition of the nature of sex, stripping that much-debated matter of morphological complications. At times, his wide outlook and his genius for broad generalizations may have put his conclusions in advance of his evidence, but his conclusions were certainly not sterile, for they led to renewed research. As we always expect from a Frenchman, his writings are clear and brilliantly luminous, so easy to read that a careless reader is in danger of missing a great deal that lies in the background.

P. A. C. Dangeard has left, in *Le Botaniste* and elsewhere, a noble record of a long life of active devotion to his subject. May that record stimulate those now working in his field, for the lower organisms and the cell have not yet yielded all their secrets.

B. BARNES

NEWS and VIEWS

Study of Public Administration

In his inaugural lecture from the new chair of public administration at the London School of Economics and Political Science on February 3, 1948, Dr. W. A. Robson welcomed the creation of the chair as a sign of the extended recognition now accorded to the study of public administration by the University of London (London: Stevens and Sons, Ltd. Pp. v+26. 2*s.* 6*d.*). It is impossible, however, for this vast field to be covered adequately in regard either to teaching or research, he said, unless far greater provision is made for senior posts at academic institutions throughout Britain. The expansion in the scale and scope of public administration is a dominant feature of our times and is to be seen not only in the growth and multiplication of government institutions and of the public corporations, but also in the new conception of the task of government. The keynote of most of the recent developments has been extreme centralization, and Dr. Robson expressed the view that contemporary trends are not in conformity with the best democratic principles and that we are not making the most efficient use of our resources of political energy, administrative ability and experience. In particular, he criticized the failure to appreciate the need for a democratic form of regional government, and supported the view advanced since in the second report of the Local Government Boundary Commission that the Commission should be given wider powers. Public ownership and the nationalization of industry both call for much greater efforts to measure the results of public administration in relation to its cost in terms of money and effort, and he believes that the question of centralization and decentralization needs discussion in the universities before a coherent body of principle is likely to be evolved for practical use.

At the Cabinet-level also, there are changes which call for further study and discussion, and such problems as questions of personnel administration, the distribution of powers, methods of control, organic relationships and constitutional development require re-examination, quite apart from the new problems presented by nationalized industries and the relations between public corporations and Parliament. He urged that the Economic Survey should be accompanied by a corresponding survey of public administration at intervals of not less than a year. Overshadowing all is the problem of how to ensure that the vast powers which are needed by the executive are conferred and exercised in conformity with the political traditions and the liberal spirit of the British people. He urged that we should cease to think of freedom only in terms of the absence of restraint and consider it also in terms of opportunity. He suggested that Parliament should take pains to define more carefully the executive powers which it confers; to state more clearly the purposes for which they are to be used; and to see not only that the rights of the public and the duties of public authorities are reciprocal, but also that the obligations of the citizen and the executive are mutual. Finally, he pleaded that the universities of Britain have a special contribution to make to the discussion of such problems, by diffusing a knowledge of the principles underlying a sound system of democratic government among the wide range of students, by helping the community to become more discriminating in its attitude to government, more critical of defects and more appreciative of achievements in the public service, and by investigating the working of institutions and analysing policies and processes. The more closely the different branches of social science can co-operate in a combined attack on the complex problems confronting us, the more effective the result is likely to be.

Annular Eclipse of May 8–9

Bad weather conditions went far to spoil the project of the National Geographic Society to link up the triangulations of Asia and of the United States and Canada by exact timing of contacts at the recent eclipse (*Nature*, March 13, p. 389). Only two expeditions—those to Rebun Jima, a little fisher-folk island off the north-western tip of Japan and to Bangkok in Siam—were favoured by clear enough conditions to get satisfactory results. Dr. C. H. Smiley, head of the last-named party, reported thin cirrus clouds, while Dr. John A. O'Keefe of the other party had ideal conditions due to a last-moment clearing. These two observations may link up the Indian geodetic triangulation with those of Japan and possibly Korea. A link-up with the American triangulation may also be possible owing to the successful photographs secured from two *B*29 Superfortress planes working from an air base on Shemya Island in the Aleutians. Short-range navigation methods were used, radar signals being sent out from the aeroplanes and received by ground stations the exact locations of which were known. Obviously fresh problems are involved in the use of data from moving aeroplanes, and it will be interesting to see the final reports when the material obtained has been examined. It is to be hoped that Great Britain, from which the suggestion first originated that eclipse observations might be used for geodetic studies, may before long take a part in securing some valuable results along these lines.

Hylean Amazon Institute

A nine-nation Conference for the creation of an International Institute of the Hylean Amazon, called jointly by the Governments of Peru and Brazil and by Unesco, has successfully concluded its deliberation at Iquitos, Peru. A convention establishing the Institute was agreed upon and will come into force upon final acceptance by the founding nations. The following nations signed the final act of the Conference: Bolivia, Brazil, Colombia, Ecuador, France, Holland, Italy, Peru and Venezuela. The scientific programme for the Institute was formulated, and a budget of approximately 300,000 dollars was set for the first year of the Institute's operation. A financial protocol was also signed by Bolivia, Brazil, Colombia, Ecuador, France, Holland, Peru and Venezuela, which determined the scale of national contributions toward financing the Institute. The United States and the United Kingdom expressed great interest in the Institute, and will study ways of actively participating in its work.

Pending the initiation of the operation of the Institute, an Interim Commission was established and the first meeting of the Commission opened in Manaos, Brazil, on May 13. In accordance with instructions from the Unesco General Conference held in Mexico last year, the Director-General has obtained the services of outstanding world experts to carry out surveys in anthropology, biology and soil science to guide the investigators of the Institute during its first years of operation in the Hylean

Amazon region. A survey will also be made of the existing scientific knowledge of the region and of the work carried out by institutions in other parts of the world on man's relation to a tropical environment.

The Wool Industries Research Association

THE report of the Director of Research for the Wool Industries Research Association for 1947–48 summarizes a five-year building plan to provide permanent buildings for plant and workshops on the lower half of the Torridon plot. Construction of a new physics block, with provision for workshops and drawing offices and a central steam-raising plant for heating and process is already in progress, and together with a new woollen block is to be completed in 1948. The provision of a new wing for a library, offices and canteen is postponed until conditions become easier. As a result of a conference of eight research associations, a standing conference is to be constituted and the exchange and study of programmes of textile research is to be commenced immediately. A survey of shortened drawing processes in members' mills has emphasized the attention which must be given to yarn characteristics when considering a reduction in the number of drawing processes; other surveys lending themselves to detailed statistical analysis have covered the occurrence of slubs and faults in yarns and the scouring and milling of woollen and worsted pieces. Progress is also reported in the measurement of the characteristics of a yarn as they affect its ultimate performance, high-draft spinning and the mathematical and experimental study of the drafting process.

Fundamental investigations noted in the report include the confirmation and extension of the theory of water absorption by wool, the diffusion of formic acid and of large molecules in keratin, the behaviour of ions in horn keratin and a physico-chemical study of the washing of raw wool. Evidence was obtained that the molecular arrangement of the amino-acid residues of which the keratin molecule is composed is much more complex than was entertained in current theories. A new method of breaking down wool to macro-molecular components apparently similar to those obtained by Mercer by the use of enzymes has yielded extremely interesting results, and investigations of peroxide bleaching have continued, as well as biochemical work on the naturally occurring polypeptides, gramicidin *S* and tyrocidine. Analysis of the peptides derived from wool containing the dicarboxylic acids and of the peptides containing cystine has continued. Biological research has included fleece studies of the Romney flock maintained at Cambridge as well as follicle studies; while in the technological field, in addition to completing a detailed examination of the resistance to washing of proprietary moth-proofing agents, the Association has suggested to the Society of Dyers and Colourists the establishment of a committee to investigate the standardization of larval testing and of washing processes appropriate for assessing moth-proofing agents. Laboratory work on combing oils, woollen oils and fastness tests has continued, as well as studies of speciality fabrics, mechanical properties of yarn and cloth, and the performance of rapid regain measurement machines on the market.

The British Boot, Shoe and Allied Trades Research Association

THE first annual report of the Council of the British Boot, Shoe and Allied Trades Research Association covers the year ended December 31, 1947. The new Council, elected in June 1947, consists of members elected on a regional basis, together with co-opted members; the Scientific, the Industrial and the Statistics Committees supervise, respectively, the work of the Scientific and Technical Division, the Industrial and Productivity Division and the Trade Statistics and Economic Research Division. The chairmen of these three Committees are also members of the Finance Committee which controls the work of the Information and Administration Division. Of the 973 consulting questions recorded during the year, 45 per cent related to wear complaints, chiefly perspiration and damage by heat. Reports are in preparation on service trials of boots containing test components, tests of a co-polymer of vinyl acetate and vinyl chloride as a lining fabric, the use of 'Mycocide L' under factory conditions, the deformation of various shoe materials, a survey of children's feet and an analysis of American Army foot measurements. An interim report on the performance and quality of welt-sewing needles has been published, and work on the water-proofness testing machine is almost complete. Experiments on the use of a Baldwin moisture meter modified for use with leather have been completed, and practical applications are being investigated. A small laboratory has been set aside for testing adhesives, and work on the effects of perspiration on upper and insole leather has continued. The Council has also endowed a Satra Research Fellowship at University College, London, tenable for two years in the first instance, for research on the structure of the human foot and on the mechanics of human locomotion, and the first fellow, Dr. R. H. Hardy, commenced his duties on January 1, 1948.

The Society for Psychical Research

IN a recently published pamphlet entitled "The Society for Psychical Research: an Outline of its History" (London, 1948. 2*s*.), which has been issued by the Society and written by its president, Mr. W. H. Salter, the author has provided a very useful account of the Society's activities from its foundation in 1882 until the present day. It is not generally realized what an immense amount of work has been done by members of the Society, a fact illustrated by its forty-eight volumes of *Proceedings*. Although the quality of the material presented is by no means uniform, the standard set by the more cautious members of the Society has always been a high one in spite of the persistent and sometimes successful attempts of its more emotional adherents to minimize the paramount importance of sound evidential material, and to introduce papers which tend to discredit the work of the Society both at home and abroad.

In his admirably objective account of the Society, the president has passed in review the various stages of its eventful career, although the general reader would scarcely realize from the author's smooth-running narrative that the two schools of thought mentioned above were always present within the Society, and that both are to this day still striving for mastery. It is these wide differences of opinion that make the Society so unlike the majority of scientific societies. For on one side we have those who believe that the Society's main function is to preserve the highest scientific standards both in research and publication, whereas on the other are grouped those who would make the Society a kind of academic and dignified spiritualist body voicing the views of those who find in popular spiritualism a system of thought and practice too crude to attract the more educated believer. As a well-balanced and judicious survey of the Society for Psychical Research past and present, this little book is to be highly commended. It shows the Society in what may be thought by some to be its best role, namely, a nucleus around which are gathered research workers of varied opinions who can use its platform for their results and get expert help and guidance when required for improving the quality of their work and assessing its value. The Society has had a long and distinguished career, and much of its published material is of the greatest value both to the psychologist and to the student of evidence and the value of testimony. To those who wish to inform themselves more fully of these aspects of the Society's work, no better introduction could have been devised than this little book.

Learning and Industry

A VALUABLE means of bringing about active co-operation between industry and the universities has recently been shown by the United Steel Companies, Ltd. At the invitation of the chairman, Sir Walter Benton Jones, fourteen mechanical and production engineering professors from British universities spent four days, beginning on April 12, in visiting the branches of the United Steel Companies at Sheffield, Scunthorpe and Stocksbridge, and in joint discussion both at the various works and at the Sheffield headquarters. Among the topics discussed were the design of Siemens open-hearth furnaces, the fuel balance of an integrated steelworks, and, led by Sir Charles Goodeve, director of the British Iron and Steel Research Association, some general research problems of the iron and steel industry. [illegible] was clear from the discussions that the research staff of the United Steel Companies were grateful for suggestions thrown out by the professors, while he latter were appreciative of the new problems put o them and which, in some cases, could usefully be followed up by them and their research staffs. By arranging this tour the United Steel Companies have shown a way in which industry and scholarship an work together for their mutual help and the well-being of British economy.

Australia and New Zealand Association for the Advancement of Science

THE report of the twenty-fifth meeting of the Australia and New Zealand Association for the Advancement of Science, held at Adelaide during August 1946, with its list of officers and research committees, balance sheet, constitution and by-laws, ectional transactions and reports of research committees, is something more than a useful reference work for the Association. In addition to Dr. P. Marshall's presidential address on "The Permanent acific" and Dr. Adrien Albert's Liversidge Centenary Lecture on "What can Chemistry Contribute to the Mastery of Disease?", it includes the addresses of the ctional presidents. Some of the latter, such as those of Dr. Ian W. Wark to the Chemistry Section on "Australian Research on the Theory of Flotation", r. W. M. Bryan on "The Geological Approach to the Study of Soils", Dr. J. Pearson on "Some Problems Marsupial Phylogeny", Dr. R. Wilson on "Facts d Fancies of Productivity", Dr. H. W. Bennetts on "The Pathological Approach to Problems of Animal isease", and Prof. E. Ashby's "Survey of Botany in the Soviet Union" appear to be of notable scientific interest and deserve the wider audience that they can now reach. Among other addresses included are those of R. Lemberg on "New Aspects of the Theory of Function of Respiratory (Hæmatin) Enzymes", A. Gottschalk on "Some Aspects of the Relationship between Chemical Structure and Enzyme Specificity", and of A. T. S. Sissons on "The Widening Front of Pharmaceutical Science".

Archæology in South Africa

THE report for 1946–47 of the Archæological Survey of the Union of South Africa has been published (Johannesburg). The most interesting piece of information therein is that the Little Caledon River has apparently cut its bed down some 300 ft. through Beaufort Sandstone since the occupation of the upper part of the valley by early Stellenbosch man. Sandstone, of course, is not such a hard material as basalt; nevertheless, a long period of time must be postulated since early man lived in those regions. Dr. van Riet Lowe has published a note in the *South African Archæological Bulletin*, 2, Pt. 8 (1947) on some interesting tanged and winged arrow-heads. This type of tool has not been found heretofore in the Union. Dr. van Riet Lowe assigns them, no doubt rightly, to a Neolithic stage of development. He does mention, incidentally, the discovery of somewhat similar arrow-heads in a so-called Solutrean *milieu* in eastern Spain; but it may be premature to assign Dr. Pericot's finds definitely to the European Solutrean culture. Spanish prehistory south of the northern mountain ranges looks mainly to North Africa for its connexions. Maybe the word Aterian will have to be substituted for Solutrean eventually. But the occurrence of tanged and winged arrow-heads in the South African Neolithic is indeed an interesting addition to knowledge.

Identification of Important Indian Timbers

IF any one factor could be picked out as justifying forestry research in the tropical and sub-tropical forest containing many timber species growing in mixture, it would consist in some popular means of identifying the various kinds. This problem first presented itself in India during the First World War, when many species of timber, practically previously unmarketable, came into use. The demand on the Indian forests was far greater in the Second World War. For the use of the Army, six leaflets entitled "How to Identify Timbers" were issued from Dehra Dun. These have now been collected together into *Indian Forest Record* (Utilisation), Vol. 3, No. 7, by the wood technologist of the Forest Research Institute, and keys and photomicrographs of the timbers that are commercially available in the different military zones of inspection have been added. The photomicrographs, on which 114 timbers are shown in 57 plates, are very clear. The writer says they will be as useful to the commercial trader as to the military authorities; he might have added also to the district forest officer and his staff in parts of the country where new timbers, previously unmarketable, are now commercially salable.

The Food of Humming-Birds

AN excellent monograph on the feeding and related behaviour of humming-birds (with special reference to the black-chin, *Archilocus alexandri*) was prepared by Frank Bené before his death in 1943 and has now been published as a Memoir of the Boston Society of Natural History (9, No. 3; October 1946). The work was carried out during 1939–42 in Phœnix and other localities of Arizona, and, because of its docility, its fondness for commercial sweets, and its regularity in returning to feed from artificial sources of food, the humming-bird proved to be an amenable subject for observation and experiment. The black-chinned humming-bird is strongly migratory, and its arrival on the spring breeding ground coincides with the flowering of its food plants. The sexes select and maintain isolated territories and meet on a neutral ground, the lex. Feeding habits of the humming-bird support Howard's theory of the nutritive function of territory. The monograph also describes the feeding routine, type and quantity of food consumed and the three feeding techniques—flower-probing, hovering-pecking and fly-catching. The Memoir contains twelve black-and-white plates which should delight all bird lovers.

The Brotherton Collection, Leeds

The eleventh and twelfth reports of the Brotherton Collection Committee, University of Leeds, covering the sessions 1945–46 and 1946–47, respectively, estimate the contents of the Collection on June 30, 1947, as 22,700 books, 15,413 pamphlets, 473 manuscripts, 4,105 deeds, 31,158 letters and 25 maps; the increase on June 30, 1946, being 61 books, 65 pamphlets and 32 letters. Undergraduates continued to use the Collection for special studies, particularly in English literature, and the return to more normal conditions was shown by an increasing number of inquiries from abroad. Many of the visits to the Collection during 1945–46 were specially arranged in connexion with an exhibition of the collection of English county atlases and road maps presented to the University by Dr. Harold Whitaker. The practice of holding exhibitions of the Collection's treasures is to be revived, and during 1946–47 an exhibition of bindings was arranged in connexion with the Leeds Conference of the International Society of Leather Trades Chemists. The re-cataloguing of books in the English literature section continued and 2,601 slips were added to the Supplementary Catalogue in 1945–46 and 880 in 1946–47. Ten books and pamphlets were presented in 1945–46 and 101 purchased, the corresponding figures in 1946–47 being 74 and 52 as well as 52 autograph letters presented.

Linnean Society of London: Anniversary Meeting

At the anniversary meeting of the Linnean Society of London held on May 24, the Linnean Gold-Medal was presented to Dr. Agnes Arber, and Trail Awards and Medals were presented to Dr. Honor Bridget Fell and Dr. Cyril Dean Darlington. The following were elected officers for the session 1948–49: *President:* Prof. G. R. de Beer; *Treasurer:* Colonel F. C. Stern; *Secretaries:* Dr. B. Barnes (Botany), Dr. A. Tindell Hopwood (Zoology). The new members of council were Mr. James M. Fisher, Mr. N. B. Kinnear, Prof. W. H. Pearsall, Dr. W. R. Philipson and Mr. N. Y. Sandwith.

South Eastern Union of Scientific Societies

The fifty-second annual congress of the South-Eastern Union of Scientific Societies will be held at Great Yarmouth during June 14–19, under the presidency of Mrs. Jacquetta Hawkes, who will speak on "Archæology and the Present". The meetings will be held in the Town Hall. The sectional presidents and the titles of their addresses are: H. J. Howard (Botanical Section), "The Mycetozoa of Sand-dunes and Marshland"; Lieut.-Colonel S. E. Glendenning (Archæological Section), "Local Materials and Craftsmanship in Norfolk Buildings"; C. D. Ovey (Geological Section), "Foraminifera in Stratigraphy with Special Reference to the Ecology of Living Forms"; Major Maxwell Knight (Zoological Section), "The Study of Bird Pellets as a Subject of Interest and Instruction to Amateur Naturalists". On June 17 there will be a "Young Naturalists' Evening", at which Nature films will be shown and a 'brains trust' held. A discussion on the functions and organisation of local societies, to be opened by G. E. W. Gosnell, will be held on June 18. The local secretary of the meeting is Mr. P. E. Rumbelow, 27 Rodney Road, Great Yarmouth; the honorary general secretary of the Union is Mr. F. J. Epps, 78 Dunwich Road, Bexleyheath, Kent.

Population and World Resources in Relation to the Family

An International Congress on "Population and World Resources in Relation to the Family" will be held at Cheltenham during August 23–28. The programme for the Congress, which has been organised by the Family Planning Association of Great Britain, includes general sessions devoted to the following topics: world resources; essential standards of living; migration as a factor in the adjustment of national populations; sociological implications of family limitation in various typical countries; birth control as a factor in the adjustment of national population; ethical and medical advantages of planned family limitation; current and future research in problems of fertility, infertility, sex and marriage; agencies for the dissemination of knowledge and propaganda. Further particulars can be obtained from the Cheltenham Congress Organiser, 37 Park Street, London, W.1.

Announcements

Sir James Chadwick, honorary fellow of Gonville and Caius College, Cambridge, and Lyon Jones professor of physics in the University of Liverpool, has been pre-elected Master of the College to succeed Mr. J. F. Cameron, who retires on September 30.

The Association of British Science Writers is holding its first forum discussion meeting on "Science and the Press" on June 9 at 7.30 p.m. at the Society for Visiting Scientists, 5 Old Burlington Street London, W.1. The meeting will be open to the public and admission is free.

A research scholarship of the value of £400 per annum and tenable for two years has been offered by the Aluminium Development Association to encourage and facilitate research in the application of light alloys to ship construction. The scholarship will be administered by a Committee of the Institution of Naval Architects and it is hoped to make the award in September. Full particulars of entry, which close on July 31, can be obtained from the Secretary Institution of Naval Architects, 10 Upper Belgrav Street, London, S.W.1.

Erratum. In the communication entitled "Transmission of Bactericidal Radiation through Glass (*Nature*, May 29, p. 856), the lettering of the tw curves should be interchanged.

Meson Scattering with Nuclear Excitation

In examining a number of Ilford *C*2 plates, loaded with boron, and exposed to cosmic rays in aeroplanes at an average altitude of 8,000 ft. for about 72 hours, we have come across an interesting track which is reproduced herewith. The track starts at one surface of the emulsion, extends for a length of about 470 μ and then suffers a sharp bend through an angle of 29° at the point *b*. It thereafter continues for a distance of 134·4 ± 0·5 μ and ends in the emulsion.

For a number of other tracks in the same plate which end in the emulsion, the total number of grains N has been counted as a function of the residual range R, and $\log_{10} N$ then plotted as a function of $\log_{10} R$. In this way we obtain a figure similar to Fig. 4 of the article by Lattes, Powell and Occhialini[1]. The tracks fall into two clearly differentiated groups, one of which can be identified as due to protons, the other as due to mesons. Now counting the number of grains as a function of the residual range for the track *eb* yields points lying *within* the set of points obtained for mesons, and on the side of higher rather than lower grain density. This allows one to identify the track unambiguously as due to a meson which comes to rest in the emulsion, though we cannot, of course, say whether it is a π-meson or a μ-meson. The grain density just after the bend is 0·76 grains/μ, which is in good agreement with that to be expected from our curves for the observed residual range of 134·4 μ. Coming now to the part of the track *ba* before the bend, we have counted the number of grains along it for every ten scale divisions of track, up to a total length of 420 μ, starting from the point *b*. The last 50 μ of track is too near the surface of the plate to allow accurate grain counts, and this portion has therefore been omitted. The result is given in Table 1.

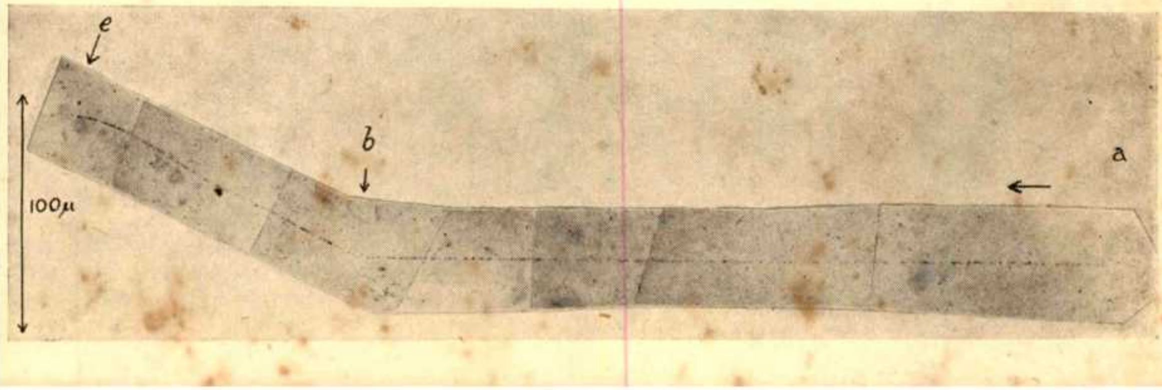
TABLE 1. *P*, PORTION OF TRACK IN SCALE-DIVISIONS; *N*, NUMBER OF GRAINS IN THIS PORTION

P	0–10	10–20	20–30	30–40	40–50	50–60	60–70
N	12	13	12	16	10	12	11
P	70–80	80–90	90–100	100–110	110–120	120–130	130–140
N	9	8	11	11	9	14	11
P	140–150	150–160	160–170	170–180	180–190	190–200	200–210
N	11	8	11	10	10	10	8

Fitting a straight line to these figures by the method of least squares, we obtain a line with a slope of 0·16 grains per ten scale divisions, per ten scale divisions, while the mean height at its centre is 10·8 grains per ten scale divisions. The standard deviation of the points from this line is 1·8 for a count of ten scale divisions. Since a scale division is 2·1 μ, it follows from these figures that the grain density near *b* is 0·60 ± 0·09, while at *a* it is 0·46 ± 0·09 grains/μ.

From our curves it follows that the residual ranges for these two grain counts are approximately 320 μ and 800 μ respectively if the particle is assumed to be a meson, giving a length of about 480 μ between the points *ba*. This is in fairly good agreement with the observed length of 420 μ. On the other hand, if the particle be assumed to be a proton, the residual ranges corresponding to grain counts of 0·60 and 0·46 grains/μ are 3,802 μ and more than 10,000 μ respectively, requiring the track length *ba* to be greater than 6,000 μ, in complete disagreement with the observed length. It can therefore be concluded with some confidence that the particle producing the track *ab* has not a protonic mass. However, since the mass determination now depends on the slope and length of the track *ba* and not on the total grain count against residual range, the determination is much less certain than in the case of the track *be*, and we cannot exclude the possibility of the particle having a mass a few times that of a π-meson.

The most obvious explanation of the bend at *b* is to assume that it is due to the scattering of a meson by collision with a nucleus in the emulsion. Now the energy and momentum of the particle just after the bend can be estimated from the grain count and the residual range, and is 1·5 ± 0·1 MeV. and 17·7 ± 0·7 MeV./*c* if the mass of the meson is assumed to be 200 *m*, where *m* is the mass of the electron. Similarly, the energy and momentum of the particle just before the bend are 3·3 ± 0·4 MeV. and 26·2 ± 1·3 MeV./*c* respectively. Since momentum is conserved, the momentum of the recoil nucleus can be deduced to be 13·8 ± 0·8 MeV./*c*. This gives it a kinetic energy of approximately 0·9 KeV., 1·2 KeV. or 0·1 MeV., depending on whether the recoil nucleus is that of silver, bromine, or hydrogen respectively. Hence even in the case of hydrogen the calculated energy is less than a tenth of what it should be for an elastic collision, namely, (3·3 ± 0·4) − (1·5 ± 0·1) = 1·8 ± 0·5 MeV. Thus, if the bend is to be explained as due to scattering, we must conclude that the recoiling nucleus is excited to the extent of about 1·8 MeV. The possibility that the meson might have been scattered with emission of radiation can be ruled out almost completely because of its low velocity. The radiation loss of mesons is 40,000 times less than that of electrons, due to their greater mass. Moreover, even in the case of electrons, radiation loss becomes negligible compared with scattering at non-relativistic velocities, and this effect would still further diminish the chance of radiation loss relative to scattering for the meson under consideration. The



mechanism for the observed bend is clear. Assuming the nucleus to be a heavy one, like silver or bromine, one finds that a proton of 10 MeV. kinetic energy moving in a suitable direction in the nucleus could absorb the required amount of energy and momentum to explain the observed tracks. The extra energy acquired by the proton would be immediately divided among the other particles in the nucleus. If the track be due to a π-meson with a mass of 300 m, then a corresponding calculation shows that the track can also not be explained by an elastic collision. In this case the recoiling nucleus would be excited to the extent of about 2·7 MeV.

There is, however, another possible explanation of the track which we have to consider, namely, that at the point b a heavy particle decays *while in motion* into a lighter one, with the emission of a neutral particle, as, for example, a π-meson decaying into a μ-meson. Assuming different values for the mass m_l of the light meson and mass m_h of the heavy meson, the mass m_n of the neutral particle can be calculated. The result is shown in Table 2.

TABLE 2

m_l	m_h/m_l	m_h	m_n/m
170	1·5	255	79·5 ± 14·7
170	1·7	289	114·8 ± 21·2
200	1·5	300	93·6 ± 17·3
200	1·7	340	135·0 ± 24·9
300	1·5	450	140·4 ± 22·4
300	1·7	510	202·5 ± 32·4
300	3·33	1000	695·5 ± 111·2

Thus assuming the mass of the light meson to be 170 m and the ratio of the masses of the heavy and light mesons to be 1·7, as in the case of the π- and μ-mesons of Lattes, Powell and Occhialini[1], we find the mass of the neutral particle to be 0·68 ± 0·08 times that of the μ-meson, giving it a mass of 115 ± 21 m. Although this agrees within the limits of error with the mass of the neutral particle required by these authors, our calculated energy release would be 2·5 MeV., whereas they find an energy release of about 10 MeV. We are therefore inclined to believe that if our track is to be explained as a decay process at all, it would have to be the decay of a heavier particle into a π-meson. The only evidence for preferring such an interpretation to that of simple inelastic scattering is that the part of the track after the bend b shows noticeably greater scattering than before the bend. Some support for this visual impression can be obtained by a more quantitative measurement of the scattering along the track. The mean square of the scattering angle $\overline{\theta}^2$ in a length t of track varies inversely as the square of the kinetic energy E. Thus $E^2\overline{\theta}^2$ should depend only on the properties of the material for a particle of given mass. We have worked out the mean value of $E^2\overline{\theta}^2$ for eight intervals of length 15 μ each before the bend, and twenty similar intervals after the bend, and obtained 9·2 and 2·5 respectively in arbitrary units, assuming the mass of the particle to be 300 m throughout. On the other hand, if the mass of the particle before the bend were twice that after the bend, the values of $E^2\overline{\theta}^2$ would become more equal. This argument has, of course, to be taken with extreme caution, since the statistics are small and the fluctuations large. If the track observed by us is really to be interpreted as the decay of a heavier particle into a π-meson, then it cannot be identified with the process suggested by Rochester and Butler[2], as the last line of Table 2 shows. The mass of the neutral particle would have to be quite different.

We may summarize the above discussion by saying that the track reported by us is due to the scattering of a meson by a nucleus in which the nucleus is not disrupted but simply excited. Although we should expect such a process to occur, this is the first time that experimental evidence appears to have been obtained showing it.

We wish to express our thanks to Prof. H. J. Taylor for his invaluable assistance. We also wish to thank Mr. Malkarnekar for help in preparing the photomicrograph.

Investigation of the Radioactivity of Rocks by the Photographic Method

MADAME IRENE CURIE has pointed out[1] the feasibility of estimating the total uranium and thorium content of rocks by using the photographic method. H. Yagoda and N. Kaplan have more recently employed the method for determining the disintegration constant of U^{238}, getting values in concordance with previous results[2]. We have now tried the method on various rock specimens and the results obtained have been definitely encouraging. The method employed is to place an Ilford Nuclear Research plate at a distance of about 0·1 mm. from a flat surface of the specimen cut with a diamond saw, and expose it for one to three weeks, depending the probable activity of the specimen. In more recent experiments the plate has been placed in contact with the cut surface, as this makes easier the identification of α-ray tracks, which all originate from one nucleus. Theoretically, from the frequencies of two-, three-, four- and five-ray stars, it should be possible to estimate the separate amounts of uranium and thorium present. Enough data have not yet been obtained to determine whether this method will prove possible.

As might be expected, the plates show that the distribution of the radioactive elements in rocks is sporadic. This specially applies to coarse-grained rocks such as granites: Fig. 1 is a photomicrograph of a very active spot obtained from a Finnish granite. More than two hundred tracks can be counted in the area shown, an area of about 7 × 10^{-4} cm.^{2}.

The average number of tracks for the same area taken over a gross area of 0·1 cm.^{2} was only about five. It will be seen that the tracks show a very definite tendency to be radial, and that the tracks increase in apparent length as they recede from the centre. The plate was separated from the rock surface by an air space of about 0·1 mm., so both observations agree with the view that the radioactive source is concentrated in a small volume of rock nearly opposite the centre of the photograph. This would agree with the usual hypothesis of the method of formation of pleochroic halos. The fact that for some rocks such large local concentration of activity occurs renders the quantitative estimation of the average radioactivity of these rocks more laborious.

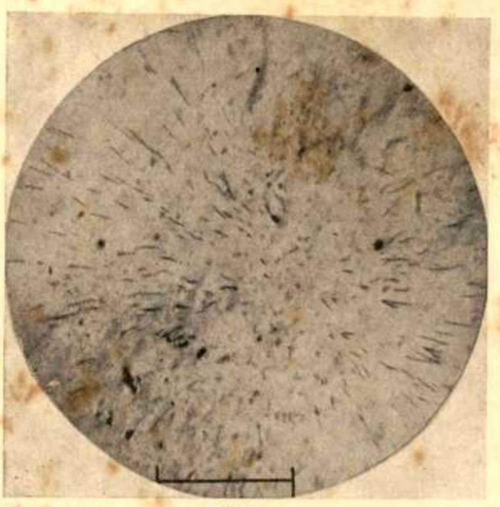

Fig. 1

It must be remembered that some of the α-tracks observed may be due to radioactive elements present either in the glass of the plate or possibly even the emulsion. This question has been investigated by developing some of the plates without exposure to any rock, and as might be expected, a fair number of tracks, most of which originate in the glass, were found. Two-, three-, four- and one five-ray star were observed: Fig. 2 is a photomicrograph of a four-rayed star which apparently actually originates in the emulsion, but such stars are rare. A rough estimate gives the number of these tracks as about 0·1 track per cm.^{2} per hour. Fortunately, as the great majority of these tracks originate in the glass, it is fairly easy to distinguish them from the α-tracks from the rock. Alternatively, the tracks on a part of the plate which has not been exposed to the rock can be counted, and the necessary correction applied to the figure obtained for the portion exposed to the rock.

The presence of these α-ray stars in our plates would seem to cast some doubt on H. E. Huntley's hypothesis that similar stars observed in plates exposed at 11,000 ft. are due to cosmic rays[3]. Our plates have been kept at sea-level, and hence their exposure to cosmic rays has been small. To date, only one undoubted cosmic ray disintegration of an atom has been found, and yet the frequency of the stars observed is at least as high as that found in Huntley's plates. It would, as a matter of fact, be surprising if the glass of the plates were so free from radioactive materials that the small number of stars observed was not present. Probably the main source of the radioactive elements is the optical sand used in the manufacture of the glass, and it would not be expected that the radioactive elements present in the sand would be nearly totally eliminated during the process of manufacture.

Lightning Arrester Discharge Currents

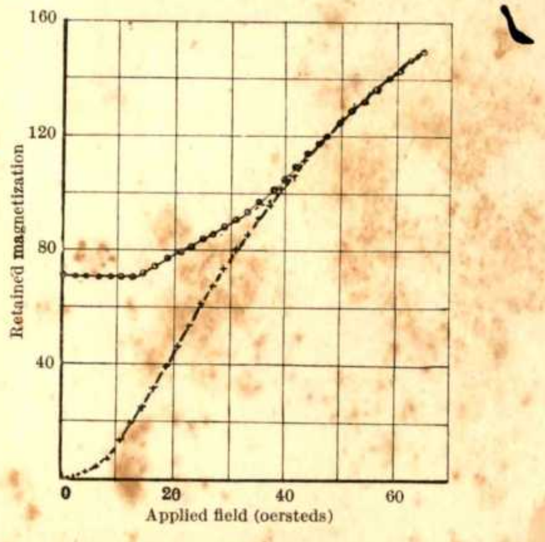
DURING the last five years an investigation has been made of the discharge currents of a number of 38,000-volt lightning arresters. The transmission system on which these arresters were installed is operated with its neutral point earthed through Peterson coils; the lines are not equipped with overhead ground wires. The earth lead of each single-phase arrester was equipped with a pair of magnetic links. In addition, paper-puncturing recorders were used to indicate when arresters had operated.

Among the results obtained last season were two of particular interest. The pairs of links involved were evaluated by the new step-method put forward by Prof. H. Norinder[1]. From the results it was apparent that the links had not been magnetized by a unidirectional current discharge. Reversals of direction of current flow were clearly indicated and could be evaluated. The magnitudes of the discharges were also evaluated by the older method[2] of comparing the relative magnetizations of the inner and outer links, assuming the presence of a single reversal. The values obtained were as follows:

Result No.	Norinder method		Value derived from relative magnetization of inner and outer links (amp.)
	Inner link evaluation (amp.)	Outer link evaluation (amp.)	
36 *S*	+1150, −390, +80	+1130, −370	+1220, −400
36 *T*	+1570, −250, +530	+1650,* − ?	+1590, −210

* Further evaluation of this link spoiled by a laboratory accident.

The characteristic curve obtained for the inner link of result No. 36 *T* is shown in the accompanying graph.



The Norinder method has been applied to the results obtained during the greater part of last year. Using this method, evidence of reversals of current flow have been obtained sufficiently frequently to show that it is not a rare phenomenon. In most cases, however, the discharges were not of sufficient magnitude to enable them to be evaluated with any degree of accuracy.

There would appear to be four possible explanations for the reversals observed : (*a*) Reversal of direction of current flow in the originating lightning flash itself[3–5]. (*b*) The record was the combined result of two or more flashes, that is, one flash made direct contact with the line conductor, others being a near miss or possibly also making contact with the conductor but being of opposite polarity. The flashes in question would have to occur within a maximum period of about five minutes or else they would have been recorded as separate punctures on the paper-band recorders. (*c*) A multiple flash, the component strokes of which did not all make contact with the line. (*d*) Restriking inside the arrester after the first current zero[6]. Many more data are required to elucidate this matter.

Unless the new method of evaluation is used, the presence of reversals such as those reported above can lead to erroneous interpretation of magnetic link observations of arrester discharge currents. This is especially liable to occur in the case of the more common small current discharges, as in such cases it is not possible to detect reversals by comparison of inner and outer link magnetizations since the outer link magnetization will be almost negligible.

It is hoped to publish fuller details of these investigations at a later date.

Effect of Lattice Distortions on the Mean Rate of Propagation of Large Barkhausen Discontinuities

THE well-known experiments by Sixtus and Tonks[1] on the propagation of large Barkhausen discontinuities have been repeated and extended, using slightly more refined methods.

The relation between the mean rate of propagation, V, and the external field, H,

$$V = A(H - H_0) \qquad (1)$$

was found to be strictly valid in all cases investigated.

Extensive experiments on a 60–40 nickel–iron alloy (which for this purpose has certain advantages over other alloys[2]) showed that A is very sensitive to defects in the lattice structure, an effect which hitherto seems to have escaped notice.

Table 1 refers to data obtained on a wire which was cold-drawn to a diameter of 0·01 cm. and then annealed at increasing temperatures, the highest (1,000° C.) including a slow cooling in a magnetic field. After this the wire was plastically stretched by a few per cent and measurements of A and H_0 again made.

TABLE 1

Condition of the wire	λ (cm.)	R ($\mu\Omega$/cm.)	H_0 (Oe)	A (cm./sec. Oe)
I	8·0	75	2·70	11,000
II	9·0	63	2·00	14,000
III	8·5	69	0·11	42,000
IV	11·5	—	0·08	38,000
V	10·0	71·8	0·56	35,000

I, cold drawn state.
II, I followed by heating for 4 hr. at 420° C. in hydrogen.
III, II followed by heating for 1 hr. at 850° C. in hydrogen.
IV, III followed by heating at 1,000° C. and slowly cooling in magnetic field.
V, IV followed by plastically stretching by a few per cent.

The last column and the last column but one contain the measured values of the constant A and H_0 in equation (1). There is a clear inverse relationship between the two quantities.

The length, λ, of the discontinuity does not vary much as a result of either cold work or annealing (cf. col. 2, Table 1).

The heat-treatment at 420° C. was aimed at producing the maximum amount of ordering in the lattice compatible with the cold-worked state. The effect of this treatment on the electric resistance, R, of the wire is very marked (cf. col. 3, Table 1), but the accompanying change in A is nevertheless small. Moreover, it is opposite in sign to the change to be expected as a result of an increased eddy-current damping.

The rate of propagation of the discontinuity in the cold-worked sample is not entirely uniform, as is indicated by the presence of irregularities in the oscillogram giving the voltage induced in the test coils surrounding the wire as a function of the time. In carefully annealed wires, on the contrary, propagation is quite smooth and at a constant rate.

Measurements were also made at the temperatures of liquid air and boiling water. This was done by passing these liquids through a glass tube surrounding the specimen.

These experiments brought to light a surprising effect, namely, that for a given wire the ratio A/R is practically independent of the temperature (cf. Table 2).

TABLE 2. Ni–Fe 60–40; diameter of wire, 0·01 cm. Measurements at T_1 = 93° K.; T_2 = 287° K.; T_3 = 368° K.

Cold-drawn state A_2 = 11,900 cm./sec. Oe					Annealed at 850° C. A_2 = 42,250 cm./sec. Oe				
T/T_2	A/A_2	R/R_2	H_0	λ	T/T_2	A/A_2	R/R_2	H_0	λ
0·32	0·35	0·36	3·36	10	0·33	0·34	0·37	0·11	10
1·00	1·00	1·00	2·44	10	1·00	1·00	1·00	0·03	10
1·28	1·36	1·39	2·20	10	1·28	1·37	1·41	0·05	10

To a less extent it might also be said that A is proportional to the absolute temperature in the region studied. Since we know of no other way of accounting for the observed substantial decrease in A with decreasing temperature except by assuming an increase in the eddy-current losses, we are inclined to suggest that perhaps a more refined eddy-current theory which makes due allowance for the fact that the rate of propagation in cold-worked samples is not uniform might account for all the facts.

A more complete account of our measurements will appear in due course in the *Philips Research Reports.*

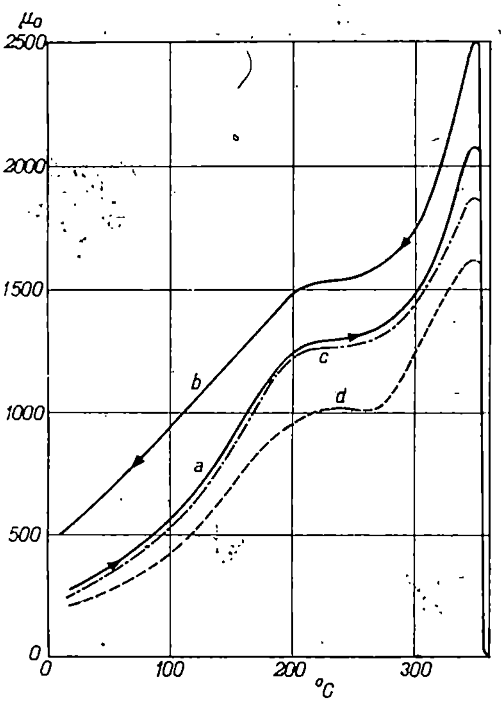
Metastable States of Nickel Characterized by a High Initial Permeability

IN text-books on the subject, it is usually tacitly assumed that the initial permeability, μ_0, of a ferromagnetic material not subject to ordering, ageing or allotropic transformations is a unique function of the temperature. We have found that this is not true for pure and well-annealed nickel.

Circular bars having a diameter of 4·5 mm. and a length of 250 mm. were examined by us in an arrangement permitting the measurement of μ_0 at any temperature between room temperature and the Curie point without displacing or touching the sample. The temperature could be varied at a mean rate of about 20° C. per minute.

It was found that the curve for μ_0 when taken at rising temperatures differs markedly from the curve obtained at decreasing temperatures (see accompanying graph). The new value of μ_0 at room temperature is nearly double that observed after demagnetizing and is appreciably higher than any value reported so far in the literature[1].



VARIATION OF THE INITIAL PERMEABILITY OF NICKEL WITH TEMPERATURE:

(*a*) at increasing temperatures; (*b*) at decreasing temperatures starting from a temperature slightly above the Curie point; (*c*) curve found after demagnetizing the sample at the temperature of the measurement; (*d*) curve found after slightly tapping the arrangement at the temperature of the measurement. Curves (*c*) and (*d*) are independent of the previous heat-treatment.

Slightly tapping the arrangement or demagnetizing the sample brings the initial permeability down to values which—though mutually different—are independent of the previous heat-treatment. A waiting period of twenty-four hours usually brings the permeability down a good deal. It was assumed by us that this might be due to slight vibrations in the building. Measurements in quieter surroundings—a small observatory—confirmed this view. The abnormally high value of μ_0 in the observatory remained constant for periods varying between ten minutes and many hours, after which a sudden—usually small—decrease in μ_0 occurred.

Observations with a vibration indicator showed that the basement of the observatory—though much quieter than our previous surroundings—also was not absolutely at rest.

Our observations thus seem to show that temperature agitation itself does not bring about the more stable condition, but that small mechanical shocks or a demagnetizing treatment are required.

In order to bring about an abnormal increase of μ_0, it is not necessary to heat the sample at a temperature above the Curie point. Actually a variation of the temperature by ± 100° suffices to bring about an abnormal increase in μ_0.

A more complete account of the measurements will appear in the *Philips Research Reports.*

Audio-Frequency Magnetic Fluctuations

A RECENT letter by Menzel and Salisbury[1] raises the question of the existence in Nature of electromagnetic waves of audio-frequencies and refers to observations covering the range 25–400 c./s. Magnetic fluctuations at these frequencies have been recorded at the Admiralty Research Laboratory, and on various occasions during the past year field measurements have been made, including some at an isolated site on Bodmin Moor, Cornwall, remote from man-made sources of electric disturbance. These measurements covered the range 5–1,000 c./s.

The detector consisted of a coil wound on a long laminated mu-metal core, the complete unit being light and easily portable. The signals were amplified, and measured by a wave analyser having a passband of 4 c./s. The entire equipment was operated from batteries.

At the higher frequencies the magnetic fluctuations are very weak, and the principal difficulty in the design of the equipment is to keep the resistance noise of the detecting coil adequately below the level of the 'magnetic noise' to be measured. To be certain that any one reading was due to magnetic noise and not to the noise of the coil itself was not always easy. Latterly, however, we have employed two similar coils for reception, located parallel to one another, sufficiently separated to make their magnetic coupling small, but at the same time close enough to ensure that their responses to magnetic fluctuations are in phase. If the coils are connected in series, the effects of the magnetic fluctuations reinforce one another; but if they are connected in opposition, these effects are cancelled. In the case of resistance noise it makes no difference which way the coils are connected provided their coupling is small. By switching the coils in series and opposition at each reading, it is then easy to decide to what extent any one measurement is due to genuine magnetic fluctuations.

The accompanying table gives typical values for the fluctuations of the horizontal magnetic field measured at Bodmin Moor in April and November 1947. These fluctuations were the same in all directions of the horizontal plane :

Frequency	Magnetic fluctuations for 1 c./s. pass band*
5 c./s.	6×10^{-8} Gauss
10	3×10^{-8}
20	8×10^{-9}
40	5×10^{-9}
100	1×10^{-9}
200	5×10^{-10}
400	7×10^{-11}
800	4×10^{-11}

* If these magnetic fluctuations were the magnetic components of an electromagnetic wave field, the corresponding electric field values, measured in micro-volts per metre, would be obtained by multiplying the above magnetic values by 3×10^{10}.

It is considered that these fluctuations are of natural origin. The absence of any directionality in the horizontal plane suggests that the fluctuations do not arise from the nearest highly populated area (Plymouth); and furthermore, the results showed no trace of the line spectrum obtained in such a populated area, other than a weak signal at 50 c./s.

The noise values show a rapid decrease with frequency, roughly inversely as the power 3/2. Beyond 1,000 c./s. it has not been possible to detect magnetic fluctuations above the noise of the existing detector system, and the observations suggest that there may exist a very silent region of the spectrum between 1,000 c./s. and the lowest radio frequencies.

Although the magnetic noise showed no directionality in the horizontal plane, it was often much less in the vertical direction, even at frequencies as low as 20 c./s. It is possible that this is due to eddy currents set up in the earth. If we suppose, for example, that the magnetic fluctuations arise from distant current movements in the atmosphere, near the earth's surface, then theory shows that the magnetic fields which they produce at ground-level at sufficiently large ranges will be largely horizontal, even at very low frequencies. In the experiments described above, the attenuation of the vertical fluctuations may have been accentuated by the fact that the ground was wet at the time. Above dry ground one would expect greater vertical fluctuations.

Structure of Plasteins

THE molecular weight of the 'plastein' precipitated from a pepsin hydrolysate of egg albumen at *p*H 4 was found to be about 300 in determinations performed cryoscopically in a phenol solution[1]. Since the average molecular weight of peptides in pepsin hydrolysate is between 300 and 400 [2], no lengthening of peptide chains seems to take place in the formation of plastein, still less protein synthesis, as had generally been thought. For this reason we regarded the plasteins as being constituted of mixtures of cyclic peptides which are formed under the influence of certain proteolytic enzymes from low-molecular peptides in protein hydrolysates[1]. Of the earlier investigators, Folley[3] alone has supported the view of the low molecular-weight structure of plasteins.

In further studies on the formation and nature of plasteins, we employed chiefly the pepsin hydrolysate of zein. Crystalline pepsin was regularly used.

(1) The molecular weight determined by the cryoscopic method in a phenol solution was ascertained to be about 300 with three preparations of zein plastein. The values in phenol solutions are, however, too low as derived from the results of plastein hydrolysis recorded below. The average molecular weight of the known amino-acid residues in zein and plastein is about 116.

(2) The formation of plastein with pepsin has a strong maximum at *p*H 4. On the acid side, the limit of the reaction is at about *p*H 2·5; on the alkaline side about *p*H 7.

(3) The amino-acid composition of plastein and zein are very similar when the values are calculated on amide-free material. Since the amide-nitrogen chiefly splits off in the pepsin hydrolysis in the form of ammonia, the plastein preparations of zein contain only two to three per cent of the total nitrogen as amide-nitrogen. We found in zein-plastein (the values for zein[4] are in brackets): arginine + histidine 7·1 (7·0), glutamic + aspartic acids 23·1 (23·1), alanine + valine + leucine + *iso*leucine + phenylalanine + methionine 39·6 (39·3), proline 8·7 (9·7), tyrosine 3·6 (3·1). All values refer to amino-acid nitrogen as a percentage of total nitrogen in amide-free material.

The results of analyses suggest that the amino-acid composition of plastein corresponds roughly to that of protein. The differences in the proline and tyrosine values seem, however, to indicate that small variations may exist regarding some amino-acids. The analysis of the amino-acid groups derived from hydrolysate of egg albumen also gives an indication of the similarity of the amino-acid composition in protein and in the corresponding plastein.

(4) The free acid and basic groups in plastein were determined in two different ways. (*a*) We found on the basis of the safranine fixation[5] the quantity of the acid groups in zein plastein (containing 1·9 per cent of the total nitrogen as amide-nitrogen) to be $19 \cdot 4 \times 10^{-4}$ mol. per gm. The calculated value for cyclic peptides (the groups binding safranine: aspartic acid, glutamic acid, tyrosine, cysteine) is about 22×10^{-4}, for open tripeptide chains about 60×10^{-4}, and for pentapeptide 45×10^{-4}. The agreement is thus fairly good for cyclic structure.

(*b*) Titration with 0·1 *N* sodium hydroxide solution with a water suspension of plastein using thymol phthalein as indicator revealed that $22 \cdot 9 \times 10^{-4}$ mol. of sodium hydroxide had been bound per gm. plastein. Formol titration gave the value 21×10^{-4}. On the basis of the quantities of aspartic and glutamic acids in plastein, the theoretical value would be about 21×10^{-4} mole per gm. plastein, when cyclopeptide is concerned, and about 42×10^{-4} in the case of open peptide chains with one amino-dicarboxylic acid residue.

Determination of amino-nitrogen by Van Slyke's method (a plastein preparation dissolved in borate–sodium hydroxide solution at *p*H 10·0) gave the following values: 5 min. shaking, 4·4 per cent, 30 min. shaking, 6·8 per cent of total nitrogen. The small quantity of amide-nitrogen and a part of the arginine nitrogen may have reacted in the first place with nitrite. This result, too, supports the cyclic structure of plastein.

(5) Plastein is formed in the pepsin hydrolysates of all proteins examined which contain abundantly amino-dicarboxylic acids. Gliadine, which contains 25·5 per cent of total nitrogen as amino-dicarboxylic acid-nitrogen, yields under the same conditions more plastein than does zein containing 18·8 per cent amino-dicarboxylic acid-nitrogen. On the other hand, amino-nitrogen did not decrease and plastein could not be obtained with papain nor with pepsin, in a papain hydrolysate of gelatine, although plastein is precipitated from the papain hydrolysate of zein with both enzymes. The results so far seem to indicate that the acid groups in the peptides are indispensable for the formation of plastein. In a mixture containing glycyl-glycine, glycyl-*l*-leucine, *l*-leucyl-*l*-tyrosine, *l*-leucyl-glycyl-glycine, *dl*-alanyl-glycine, chloracetyl-*l*-tyrosine and hippuryl-glycine, amino-nitrogen was not lowered by pepsin action at *p*H 4, nor was plastein precipitated.

(6) In the trypsin hydrolysates of zein and casein, pepsin produced at *p*H 4 only 1–1·5 per cent plastein of the weight of protein used. In corresponding circumstances, ten to fifteen times more plastein was obtained from pepsin hydrolysates. Since pepsin and trypsin break the peptide bonds of protein at different points, it probably explains the difference. In the pepsin hydrolysis of zein, the peptide chain seems to break at the point nearest glutamic acid[2].

(7) Plasteins are slowly hydrolysed in hydrochloric acid at *p*H 1·5 at the opening of the ring. The reaction takes place much more rapidly under the action of pepsin in the same conditions. Acid hydrolysis (*p*H 1·5 and 37° C.) without pepsin brought 67 per cent of the plastein into solution in 33–55 days. On the basis of the amino-groups set free the average molecular weight of cyclopeptides would be the same as that of tetrapentapeptides. In the soluble and insoluble fraction the amount of amino-dicarboxylic acids seems to be practically the same, which supports the idea of each cyclopeptide molecule having one amino-dicarboxylic acid residue. On the contrary, proline is accumulated in the insoluble fraction. The soluble fraction, again, contains considerably more basic acids as well as acids of the group alanine + valine + leucine + *iso*leucine + phenylalanine + methionine than does the insoluble fraction.

The elementary composition of zein plastein (water and ash-free material) was as follows: C = 54·3, H = 7·6, N = 12·9 (calculated values for cyclic peptides: C = 54·1, H = 7·1, N = 13·8). Nitrogen of the amino-acids hitherto estimated in zein accounts for 94 per cent of the total nitrogen. The rest of the nitrogen is still of unknown nature. The calculated values are therefore only approximate.

We regard the present results as confirming the concept of the cyclic structure of plasteins. A detailed account of our work and further developments will be published in *Acta Chemica Scandinavica*.

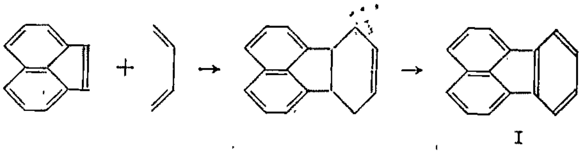
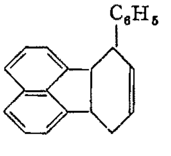
A Synthesis of Fluoranthene Derivatives

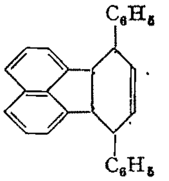
IN a recent investigation[1], the theory has been put forward that the formation of aromatic hydrocarbons in the high-temperature cracking of petroleum or petroleum fractions is due to diene syntheses between butadiene, which is one of the primary cracking products, and olefinic hydrocarbons. It occurred to us that fluoranthene (I), which is a characteristic product of this aromatizing cracking, may be formed from acenaphthylene and butadiene by the following reaction:



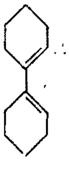
It has, indeed, been found that acenaphthylene reacts easily at 160–200° with dienes to give hydrogenated substituted fluoranthene derivatives: from 1-phenyl-butadiene and 1·4-diphenyl-butadiene, for example, 10-phenyl- and 10 : 13-diphenyl-9 : 10 : 13 : 14-tetrahydro-fluoranthene (II, III) have been obtained.



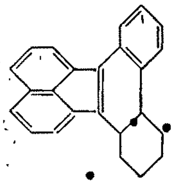
II



III



IV



V

Compound (II) had m.p. 156°, after recrystallization from alcohol (calc. for $C_{22}H_{18}$: C, 93·6; H, 6·4; found: C, 93·6; H, 6·4), and (III) had m.p. 202°, after recrystallization from chlorobenzene (calc. for $C_{28}H_{22}$: C, 93·9; H, 6·1; found: C, 93·6; H, 6·1).

With dicyclohexenyl (IV) the condensation seems to be accompanied by partial dehydrogenation and the analysis of the product corresponded to formula (V), of a 10 : 11-benzo-12 : 13-tetramethyleno-12 : 13-dihydro-fluoranthene[2]; it crystallized from a mixture of chlorobenzene and butyl acetate as a white, crystalline powder (calc. for $C_{24}H_{18}$: C, 94·1; H, 5·9; found: C, 93·9; H, 5·7).

It is interesting to note that sorbic acid behaves also as a diene[3]; in the course of the condensation with acenaphthylene, however, the carboxyl group is split off.

Acenaphthylene behaves, therefore, towards dienes like indene[4] and certain styrene derivatives[5]. This is in keeping with the fact that it contains an evidently very reactive double bond which makes the hydrocarbon also prone to polymerization and co-polymerization reactions[6,7].

A detailed description of the experiments will follow when the obvious possibilities of extension of this reaction will have been explored. It becomes possible to determine the position of substituents entering the fluoranthene molecule[8], from the location of substituents in the acenaphthene molecule, the reactions of which have been thoroughly investigated[9].

Chemical Mechanism of Permanent Set

The permanent set which strained wool fibres acquire in steam or boiling water is believed to be due to two consecutive intramolecular reactions, namely, hydrolysis of the disulphide bonds to give sulphenic acid and mercapto side-chains, followed by condensation of the sulphenic acid, or the aldehyde to which it gives rise on decomposition, with the basic side-chains of lysine and arginine[1]. Disulphide bond breakdown promotes relaxation, and the relaxed structure is stabilized by the new cross-linkages. The main evidence that the basic side-chains play an essential part in the linkage-rebuilding reaction is the failure of deaminated fibres to acquire a permanent set in steam. It seemed desirable that further evidence should be obtained because of recent suggestions[2] that the breakdown and re-formation of hydrogen bonds between the peptide chains may be sufficient to impart a permanent set to strained fibres. The setting power of wool treated with 2 : 4-dinitrofluorobenzene has therefore been examined.

Purified Lincoln root wool was treated with 2 : 4-dinitrofluorobenzene according to Sanger's procedure[3]. The wool (0·2 gm.) was first wetted out with a solution of sodium bicarbonate (0·2 gm.) in water (5·0 ml.). After adding a solution of 2 : 4-dinitrofluorobenzene (0·2 ml.) in ethanol (10 ml.), the wool was heated in the reagent for 23 hours at 40° C., the resulting gain in weight being 9·4 per cent. For reference purposes, a further sample of wool was treated with all the reagents except 2 : 4-dinitrofluorobenzene for 23 hours at 40° C. The setting power of these wools was then compared with that of untreated wool.

Each fibre was stretched 40 per cent in distilled water and set by immersion in a boiling 2 per cent solution of borax for 30 minutes. To determine the extent and permanence of the set, the fibre was then released in boiling water and its length redetermined at intervals. A summary of the results is given in the accompanying table, each value being the mean of ten observations on different fibres.

Wool	Percentage set retained after release in boiling water for 0 min.	2 min.	15 min.	60 min.
Untreated	40·0	26·1	25·3	24·4
Buffer-treated	40·0	24·0	23·2	21·0
Treated with 2 : 4-dinitrofluorobenzene	40·0	16·9	15·3	11·8

Since the setting power of wool is reduced to such a striking extent by treatment with 2 : 4-dinitrofluorobenzene, it seems reasonable to conclude, in accordance with earlier evidence, that the free amino-groups of wool play an essential part in the cross-linking reaction which is responsible for permanent set.

We are indebted to Mr. W. R. Middlebrook for the preparation of the wools used in this investigation.

Energy of the Central C–C Bond in Diphenyl

The value of the energy of the central C—C bond in diphenyl (that is, the heat of dissociation of the molecule into two radicals (or atoms) formed by the fission of this bond) is of considerable interest. The difference between the energy of this bond and the energy involved in the C—C bond of ethane provides a measure of conjugation which was generally considered as 6–8 kcal. only[1]. We use the following two thermochemical equations for the calculation of the energy of the central C—C bond in diphenyl:

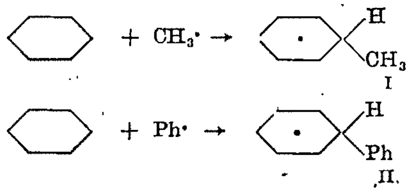
$$\Delta H_f(C_6H_5.C_6H_5) = 2\Delta H_f(C_6H_5) - D(C—C);$$

$$2\Delta H_f(C_6H_6) = 2\Delta H_f(C_6H_5) + 2\Delta H_f(H) - 2D(C—H).$$

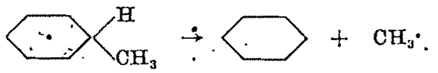
The heats of formation of diphenyl and benzene were estimated by Huffman[2] as 20·8 kcal./mole for solid diphenyl and 11·6 kcal./mole for liquid benzene. The heat of sublimation of diphenyl is 16·4 kcal./mole[3], that of vaporization of benzene 8·1 kcal./mole. For the C—H bond energy in benzene we accept the suggested value of 106 kcal.[4], which seems to be very plausible. Thus we obtain for the central C—C bond energy in diphenyl a value of 110 kcal. Its strengthening as compared to the C—C bond in ethane is 25 kcal., which shows how considerable is the contribution of the conjugation to the bond energy. This strengthening effect makes it possible to predict the length of the central C—C bond in diphenyl as 1·43–1·45 A., using the relationship between the bond energy and bond length.

There are two experimental studies dealing with the length of this bond. Dhar used the rotating crystal X-ray technique[5]; his value is 1·48 A., the estimated accuracy being about 10 per cent. Karle and Brockway[6] used an electron diffraction method. Assuming that both phenyl rings are regular hexagons having sides of 1·39 A., they find for the central C—C bond a length of 1·54 A.; if they assume the hexagons to be slightly irregular, having sides of 1·38 A. and 1·40 A., it is 1·48. In view of the great strengthening of this C—C bond, found in the present work, it seems that it has a high degree of double-bond character, which implies that the phenyl hexagons are strongly deformed. Therefore we suggest that the correct value for the central C—C bond in diphenyl which should be obtained from the electron diffraction study is even less than 1·48 A. The assumption that the hexagonal rings in diphenyl are irregular is supported by Jeffrey's work[7], which indicates the irregularity of the phenyl rings in dibenzyl.

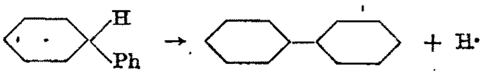
Chemical evidence also indicates that the energy of the central C—C bond in diphenyl is considerably increased and is certainly greater than 106 kcal. It is known[8] that free radicals produced in solutions of aliphatic hydrocarbons extract hydrogen from them. Methyl radicals thus produce methane and phenyl radicals give benzene. In benzene solution, however, methyl radicals do not extract hydrogen at all, and phenyl radicals react giving diphenyl. To show that this is the result of a reaction with benzene, and not a result of the dimerization of phenyl radicals, chlorobenzene was used as a solvent instead of benzene. In this solvent the main product of the reaction is *p*-chlorodiphenyl. We suggest that these facts should be explained by the following mechanism:



The point inside the ring symbolizes the odd electron. We may assume that the intermediates (I) and (II) stabilize themselves by releasing that component which is least strongly bound. In the case of (I), the most weakly bound component is CH_3 and the reaction is

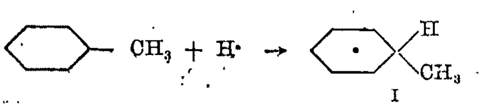


Therefore the net result is that no reaction occurs, as is observed experimentally. In the case of (II) the product is diphenyl, showing that the phenyl group is more strongly bound than the hydrogen atom.

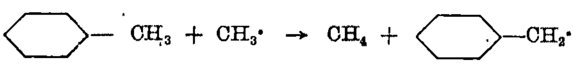


We conclude, therefore, that the C—C bond of diphenyl is stronger than the C—H bond in benzene. This must be stronger than the C—H bond in methane, because the methyl radical is not able to extract hydrogen from benzene (whereas it can extract hydrogen from an aliphatic solvent).

Another argument in favour of the proposed mechanism is found in the observation of Szwarc[9] that hydrogen atoms can react with toluene giving benzene and methane. In this case the intermediate (I) is obtained by the reaction



and this decomposes, as stated above, giving benzene and the methyl radical which gives methane by the reaction:



The benzyl radicals, being very stable, are removed by dimerization. Hence the value of 110 kcal. for the central C—C bond in diphenyl is borne out by additional chemical evidence.

Stress Corrosion

No really satisfactory explanation of stress corrosion (season-cracking) in brass and similar alloys has yet been offered, and in a recent critical review, Read, Reed and Rosenthal[1] were forced to conclude, somewhat unconvincingly, that stress corrosion might be due to an inherent susceptibility of crystal boundaries to corrosive attack on account of their 'lattice imperfection'. This view, however, would imply that grain boundary corrosion is a normal form of attack instead of being, as it is, abnormal.

It may be recalled that stress corrosion occurs only when susceptible alloys are internally stressed and then kept in certain specific corroding environments. These stressed alloys may be stored indefinitely in a pure atmosphere and, moreover, do not crack indiscriminately in all corroding media. Thus stressed brass does not crack in nitric acid (although, of course, it is attacked and dissolved), but cracks readily in air containing a mixture of ammonia, water vapour and carbon dioxide[2].

In speculating on possible mechanisms, I have previously suggested[3] that the basic cause might be selective chemical attack at the grain boundaries, localized by the formation of a protective film of corrosion product over the faces of the alloy crystals. Such a film might conceivably be protective only when its structure corresponds to the regular structure of the underlying crystals. At the grain boundaries where the regular structure of the alloy is interrupted, discontinuities in the adhering film might be expected. The effect of stress is considered to be simply that of widening the cracks first formed and thereby accelerating attack.

An observation made in these Laboratories on the stress corrosion of 9 ct. gold alloys in acidified ferric chloride solution lends support to this hypothesis. Alloys containing 37·5 per cent of gold with the balance made up of copper, silver and zinc, cold-rolled to about 80 per cent reduction in thickness, crack in less than five minutes in this solution. If, however, a sample, protected on one side with wax, is immersed so that the exposed surface bears against a small rotating brush, no cracking can be detected after thirty minutes, although considerable general corrosion takes place.

It seems difficult to account for this result on any grounds other than that of the removal of a local protective film from the surface of the metal. It is hoped that it may be possible to continue this work and publish a more detailed study elsewhere.

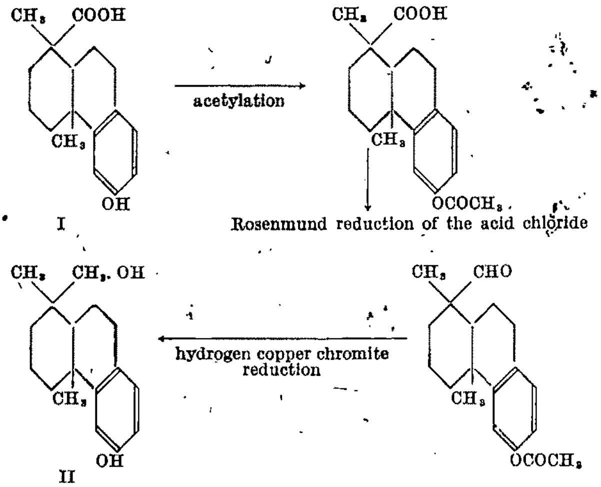
Podocarpic Acid as a Source of an Œstrogenic Hormone

Podocarpic acid occurs as crystalline 'heart shakes' in the wood of *Dacrydium cupressinum*, a forest tree endemic to New Zealand. It has been shown to possess the structure I by the work of Sherwood and Short[1] and Campbell and Todd[2,3]. The latter workers established that the 7-*iso*propyl derivative of podocarpic acid differs from 6-hydroxydehydroabietic acid only in the configuration of the methyl and carboxyl groups at C_1. The carboxyl group in podocarpic acid is, in fact, much more highly hindered than that of other resin acids.

In the course of their study of the configuration of podocarpic acid, Campbell and Todd[3] prepared 6-methoxy podocarpinol (for conversion to the 1-ethyl compound by the Wagner Meerwein rearrangement) but did not demethylate to podocarpinol II.



Fieser and Campbell[4] had previously prepared 6-hydroxydehydroabietinol and found it to possess considerable œstrogenic activity. Since this compound differs from podocarpinol only in configuration at C_1 and the presence of an *iso*propyl group at C_7, it was thought that podocarpinol might also possess œstrogenic properties.

We have recently prepared podocarpinol through the route shown, which differs slightly from that employed by Campbell and Todd. Preliminary physiological tests carried out by I. G. Cunningham, of the Animal Research Station, Wallaceville, New Zealand, suggest that podocarpinol possesses œstrogenic activity.

Details of the preparation of this compound and of the physiological tests will be reported fully elsewhere. Other modifications of podocarpic acid of possible hormonal activity are also in course of preparation.

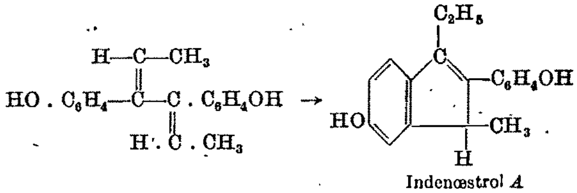
Isomerization of Dienœstrol

During experiments on the metabolism of dienœstrol in man and in animals it was noticed that hydrolysis of dienœstrol-containing urines, 1 N with respect to hydrochloric acid, always entailed a loss of about 90 per cent of the original œstrogenic activity. Further, chemical determination of the dienœstrol content of such urines by the method of Sahasrabudhe and Wilder Smith[1] showed an even greater loss of œstrogen after hydrolysis. In working out the latter method, dienœstrol was added to benzene extracts of hydrolysed urine, so that the added dienœstrol escaped the hydrolysis process. Afterwards it was found that hydrolysis of dienœstrol glucuronide[2] under similar conditions gave negligible yields of the free œstrogen (cf. Stroud[3]). On the other hand, the same hydrolysis technique (1 N hydrochloric acid, 3 hr. refluxing) gave excellent yields of hexœstrol from hexœstrol monoglucuronide. Thus it was suspected that the dilute acid was decomposing the dienœstrol liberated.

This was confirmed by treating dienœstrol (m.p. 232°) for 1 hr. under reflux with 1 N hydrochloric acid in a stream of nitrogen, when an 80 per cent yield of an isomer, m.p. 175–176°, was obtained which was not identical with Hobday and Short's[4] *iso*dienœstrol, m.p. 189°. Its acetate, benzoate and *p*-nitrobenzoate were prepared and shown to be isomeric with those of dienœstrol but not identical.

A search of the literature revealed that Adler and Hägglund[5] prepared the same isomer from dienœstrol by treating its chloroform solution with boron trifluoride. These authors identified the substance as 1-methyl-2-(*p*-hydroxyphenyl)-3-ethyl-6-hydroxyindene, which they called 'indenœstrol *A*'.



Indenœstrol *A*

We have found this indene to possess about one tenth of the œstrogenic potency of dienœstrol, when tested by the method used in this Institute[6], thus accounting for the originally observed losses of activity on hydrolysis of dienœstrol-containing urines.

It has been found that, as well as 1 N hydrochloric acid, 1 N sulphuric and 1 N phosphoric acids are equally effective in realizing the same cyclization. This presumably may take place by 1 : 4 addition of the elements of water or of the respective acid, followed by resplitting off of the hydroxy group or the acid radical with the hydrogen atom in the ortho position. Similar mild conditions were required for the cyclization of other comparable types of dienes. The addition of a trace of hydrogen chloride or concentrated sulphuric acid to a solution of dienœstrol in glacial acetic acid in the cold gave a good yield of the same cyclization product after a very short reaction period.

Fuller details will be published elsewhere.

Glycerol Dichlorhydrin and Vitamin A

The use of 'activated' glycerol dichlorhydrin as a reagent for the colorimetric or absorptiometric estimation of vitamin A has been proposed by Sobel and Werbin[1]. As reported, the reaction appears attractive in view of the stability of the chromophor, which makes for ease of measurement. A disadvantage is the low activity of the reagent compared with chloroformic antimony trichloride (Carr–Price reaction); the E(1 per cent, 1 cm.) 550 mμ value per unit of vitamin A is only about 25 per cent of the corresponding E(1 per cent, 1 cm.) 620 mμ (Carr–Price) value. The pure compound does not react at all; 'activation' is effected by distillation with 1–2 per cent antimony trichloride[1]; but no account of what causes 'activation' has yet appeared.

It has been found here that the activating principle is hydrochloric acid (or, perhaps, hydrogen ions, in so far as sulphuric acid has some activating effect), small quantities of which are formed during distillation. The same result, therefore, can be obtained more easily by the addition of about 2 per cent of concentrated hydrochloric acid to the dichlorhydrin. If used within a short time of mixing, the product behaves in a similar manner to that activated by the original method. On storage, the activity increases still further, but does not approach that of the Carr – Price reaction. On the other hand, the stored reagent loses the very desirable property of stability of the chromophor, which develops and fades in much the same way as with the Carr – Price reagent.

It appears, therefore, that the reagent can be made sufficiently sensitive to replace the Carr – Price reagent only at the expense of the advantage which it claims over it, namely, stability of the chromophor.

Pressor Effect of Renin on Pulmonary Artery Pressure

In 1940 Katz and Steinitz[1] reported that following the production of hypertension in dogs by means of an experimental renal ischæmia, no change was observed in pulmonary arterial pressure. These workers used a modified London cannula technique so that observations could be made without anæsthesia in the intact animal. Using a similar method, Friedberg, Katz and Steinitz[2] found an increase in pulmonary arterial pressure in the dog after the injection of renin. They concluded that this was not due to a vasoconstrictor effect on the pulmonary bed, but to a reflexion of the change in systemic blood pressure through back pressure on the pulmonary circuit. We have confirmed the pressor effect of renin on the pulmonary artery pressure but are at variance with the opinion of the previous workers as to its causation.

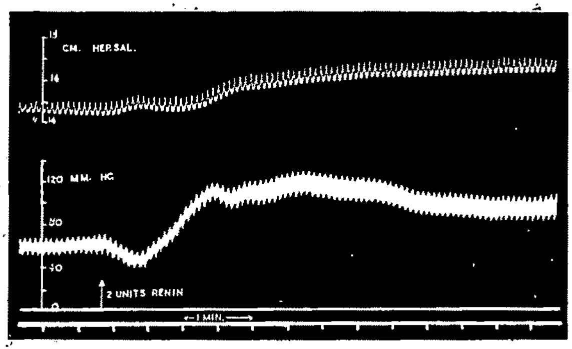
Renin was prepared from rabbits' kidneys by a modification of the method of Helmer and Page[3], and a study made of its effects on pulmonary artery pressure in dogs, a simultaneous record of femoral artery pressure being taken. Renin was injected into the femoral vein. Femoral artery pressure was observed by cannalization of the artery, a mercury manometer recording on a kymograph.

Pulmonary artery pressure was recorded by tying a T cannula, connected with a heparin-saline manometer, into the pulmonary artery extra-pericardially. Lateral pressure was therefore recorded in continuity. Such a procedure necessitated thoracotomy, performed by sub-periosteal resection of the sixth rib. Observations have been made with an open chest under pump respiration.

In all cases a rise in pulmonary artery pressure was observed. In the particular record shown, the initial blood pressure is rather low, in that it was taken from an animal on which a pneumonectomy had previously been performed, in the course of other work by one of us. Two units of renin, assayed on a 2-kgm. cat, were injected.

Both systemic and pulmonary artery pressures rose, the systemic reaching a peak in 2½ min., the pulmonary artery in 6½ min. Each pressor effect was sustained for 13 min. These figures apply to the particular experiment of which a portion of the record is shown, but similar durations were found in all cases. Before the pressor effect, the ratio between systemic and pulmonary artery pressures was 6 : 1, during the effect 10 : 1. Therefore the rise in pulmonary artery pressure was absolutely and relatively much less than the rise in systemic arterial pressure, although the durations of the two were similar. The slight initial rise in pulmonary artery pressure is due to the transient increase in venous return to the right heart occasioned by the injection of 2 ml. renin and 2 ml. saline wash.

While agreeing with the findings of Friedberg, Katz and Steinitz that the injection of renin produces a rise in the pulmonary artery pressure, our findings as to the details of this pressor effect differ from those of these authors, in that they found a greater percentage increase in pulmonary artery pressure than in systemic arterial pressure, which former rise was of shorter duration.



The pressor effect on the pulmonary artery pressure as described and illustrated in the figure is presumably due to one of, or a combination of, three causes: (*a*) bronchiolar constriction produced by renin; (*b*) a back pressure effect from the rise in systemic arterial pressure; (*c*) direct vaso-constriction, by renin, of the arterioles of the pulmonary circuit.

Further analysis of the cause of the effect is proceeding.

A Culture Method for *Lymnæa truncatula*

The amphibious snail *Lymnœa truncatula*, which serves as an intermediate host of the liver fluke, *Fasciola hepatica*, has been found in the past to be somewhat difficult to maintain in laboratory culture. In connexion with current work on the epidemiology of the severe disease of grazing animals which is caused by this parasite, one of our first problems was to establish satisfactory means of culturing the snail. Our attempts have proved so far successful that we are able to grow the snails in unlimited numbers, at different seasons of the year and to a larger size than they usually attain in their natural habitat.

On account of the particular interest of this mollusc and its association with *Fasciola hepatica* in the teaching of biology, as well as for the benefit of research workers in the field of parasitology, we felt that a description of the culture method might be of interest and value.

Having met with little success by aquatic culture methods, we proceeded with an attempt to reproduce in glass and earthenware vessels the natural habitat of the snail. This habitat comprises the small open mud flats that lie between pools of shallow water and low grassland. Finally, we developed the following technique. Unglazed earthenware pans, without holes in the bottom, 12–18 in. in diameter, of the kind used by nursery men serve as containers for the mud. Before use the pans are soaked for some days in pond water, then they are dried and coated, on the outer surface only, with paraffin wax, in order to prevent undue loss of water by evaporation. The mud which is to form the substratum of the culture is mixed with pond water in such proportions as to give it a wet plastic consistency. It is then sterilized by heat to destroy unwanted trematode infection and is placed in each pan in such a way as to form an even slope extending from near the upper lip on the one side to the floor of the pan on the other side. Depressions are made on the surface of the slope in several places, simulating on a small scale the footprints of animals, and sufficient pond water is poured over the surface of the mud to form a small pool at the bottom of the slope. The pan is then covered by a piece of glass and placed in a greenhouse where there is abundant light, to encourage the growth of algæ, and heat adequate for rapid development of the snails.

In two or three weeks the mud becomes covered with a thick growth of algæ and is then ready for the introduction of the snails. A light sprinkling of a mixture of equal parts of finely powdered natural chalk and fine oatmeal flour is applied to the surface of the mud at weekly intervals. This supplement to algal food, along with the addition of distilled water which is poured over the surface of the mud to make up for slight loss by evaporation, is all that is needed for the maintenance of the culture. It is important that the water and the mud should be of the most suitable kind for the culture of this snail, and it has been our practice to collect the mud from a heavy clay soil on which the snails are found to thrive particularly well in the natural state. The water used in the first preparation of the mud slope and for the first pool in the culture dish is also collected from this natural habitat. The sterilization of the mud is only carried out to eliminate unwanted fluke infection for the purpose of our particular work, and might not be necessary for ordinary purposes.

Our experience has revealed a much more rapid rate of multiplication of this snail than we had anticipated, and maintenance of a culture is such a simple matter that there would appear to be every reason for developing its use in the teaching of biology for demonstrating the life-history of a trematode.

Resistance to 'Inanition' in Grass Seedlings

Resistance to 'inanition' in the early seedling stage of various species of herbage grasses when grown in competition with older established plants has been reported by Chippindale[1,2]. Recent observations on perennial ryegrass (*Lolium perenne* L.) suggest that a similar resistance occurs in larger seedlings, nine to ten weeks old, both in competition with plants of the same age and species, and also

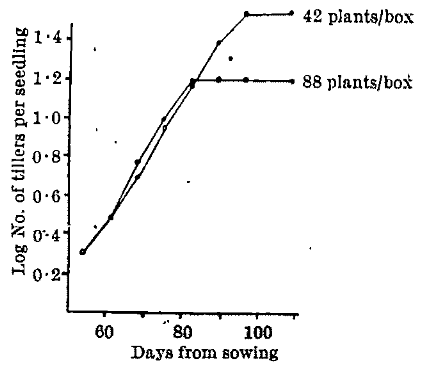

Fig. 1. MODAL SEEDLINGS FROM BOX POPULATIONS OF DIFFERENT DENSITIES. SOWN JAN. 20, 1947

when grown as single individuals with a limited root range and supply of soil nutrients.

In seedling studies on perennial ryegrass, attempts were made to obtain standard measurements of growth, which, unlike the usual dry-weight determination, did not involve destruction of the seedling, and could thus be traced throughout the life of the plant. Tiller number per seedling proved to be one of the most useful of these measurements, being highly correlated with dry weight, a typical box population giving $r = + 0{\cdot}7416$, $n = 41$, $P < 0{\cdot}001$. For these experiments, any tiller visible above its subtending leaf-sheath was given unit value.

During early seedling growth, tiller number increases exponentially with time for each plant (Figs. 1 and 2), the exponential rate of tiller production decreasing with decrease in temperature, until below 38–40° F. no tillering occurs. For any one set of environmental conditions, this rate of tiller production is similar in all seedlings of a population, high or low tiller counts being the result of early or late initiation of tillering (Fig. 2). There is a highly significant correlation between tiller number and rate of leaf production in the initial stages of seedling growth, as would be expected since the tiller arises as a bud in the leaf axil. A typical example gives $r = + 0{\cdot}6350$, $n = 35$, $P < 0{\cdot}001$.

When seedlings are grown with limited root range and soil nutrients, either in a box population or individually in small paper pots, after a time the initial exponential growth is sharply curtailed. Tillering ceases and leaf production is greatly reduced and may stop completely. This situation presumably corresponds to the 'inanition' observed in very young seedlings.

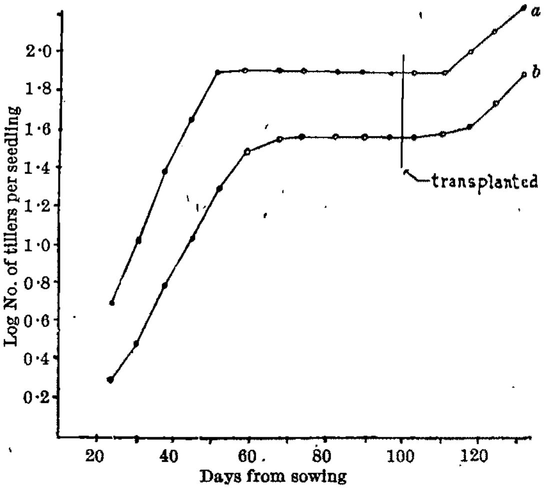

Fig. 2. EARLIEST (*a*) AND LATEST (*b*) TILLERING SEEDLINGS FROM INDIVIDUAL POTS. SOWN JUNE 29, 1947

Fig. 1 shows the increase in tiller number with time, for modal single plants from box sowings of Irish commercial ryegrass, at seedling densities of 42 and 88 plants per box. This gives an average root space per plant of 259 and 124 c.c. respectively. There is no difference in the exponential rates of tillering in the two boxes, but tillering ceases much sooner with the denser spacing. These seedlings were transplanted to the field 110 days after sowing and quickly began to tiller vigorously. In these box sowings there was no competition for soil moisture, water being supplied regularly. The other possible limiting factors were competition for light, root interaction, and competition for soil nutrients. To eliminate the effects of root interaction and competition for light, seedlings from the same sample were grown individually in small paper pots of cubic capacity 195 c.c. Fig. 2 shows the increase of tiller number with time, for the earliest and latest plant to begin tillering. There is again no great difference in the initial rates of tillering, and for each plant, tiller production suddenly ceases, presumably when the soil nutrients in the pot have become exhausted. In general, seedlings which begin tillering earlier reach a higher limiting tiller number, even in the absence of inter-plant competition, and also attain their limiting size earlier.

When tillering had ceased in all these seedlings, each was transplanted to a larger pot (2,025 c.c.), thus giving a further supply of soil nutrients. In each case, tillering recommenced after a short interval and proceeded exponentially. By the time growth started again, the most highly tillered seedling had remained in a state of 'inanition' for 60 days, without any apparent dying-back of any of the tillers.

These observations, although confined to perennial ryegrass, do suggest that this resistance to 'inanition' caused by lack of soil nutrients may be an important factor, not only in initial establishment, but also in subsequent competition in the sward.

Occurrence of Volcanic Bomb in the Agglomeratic Slates of Kashmir

THE specimen of volcanic bomb described here was collected in June 1946 by Mr. S. R. N. Rao, reader in geology, University of Lucknow, from a ridge near the village of Bren (lat. 34° 6½′ N., long. 74° 52¾′ E.) about 5½ miles north of Srinagar. It comes from the formation known as the Agglomeratic Slates, which form the lower part of the Panjal Volcanic Series. They are gritty or greywacke-like, and often grade into slates. In the fine matrix, angular fragments of quartzite, slate, porphyry, granite, etc., are distributed at random. The Agglomeratic Slates of Bren contain Lower Gondwana plants, associated with a series of sandstones and shales containing a marine brachiopod fauna[1] and *Eurydesma.*

Two views were put forward by Middlemiss[2] for explaining the origin of the Agglomeratic Slates of Kashmir: (1) that these rocks were a product of explosive volcanic activity and sub-aerial deposition; (2) that the deposit resulted from frost action under glacial conditions, the frost-weathered matter being transported to lakes through the agency of floating ice. Wadia[3], after a detailed study of the rocks, favours a pyroclastic origin for the Agglomeratic Slates.

VOLCANIC BOMB FROM BREN SPUR NEAR SRINAGAR, KASHMIR. 3/5 NATURAL SIZE

Our specimen appears to be the broken half of an ellipsoidal volcanic bomb. It measures 5·7 in. along the longer axis and 2·3 in. along the shorter. The structure is clearly revealed by the broken surface. There is an outer crust, of an average thickness of about ¾ in., enveloping a core of typically vesicular rock. The crust is compact, slightly earthy and greenish-yellow in colour. The core is yellowish-brown, with cavities which are elliptical or triangular in shape and aligned parallel to the length of the bomb. If the bomb had been completely preserved, its thickness through the centre would have been about 3·6 in. The outermost portion of the crust appears to have been of a deep brown colour. A small patch of this colour, about 4 mm. in thickness, can still be seen on one side.

A detailed petrological study reveals that the rock of the volcanic bomb is felso-andesite.

The discovery of a volcanic bomb in the Panjal Agglomeratic Slates proves beyond doubt that these rocks are due to explosive volcanic activity.

I am obliged to Mr. Rao and Dr. P. K. Ghosh, of the Geological Survey of India, for confirming my observations.

Proposed Central Publication of Scientific Papers

MANY of the problems of scientific publication that will be considered at the forthcoming Scientific Information Conference called by the Royal Society of London for June[1] could be solved by use of the method of auxiliary publication that has been in use in the United States since 1936 [2,3].

Auxiliary publication on demand does not interfere with the free and normal channels of scientific publication. The benefits of the central distribution of scientific papers proposed by Bernal can be obtained without the dangers of centralized control set forth by Sir George Thomson and Dr. J. R. Baker[4].

Some three thousand scientific papers, called 'documents', are on deposit with the auxiliary publication service of the American Documentation Institute at Washington, D.C., and additional material is being deposited constantly. A catalogue of such ADI Auxiliary Publications is available[5]. Primarily, the existence of the 'document' and its availability on order is notified to scientific men and others by publication of notices in the journals whose editors transmit the documents for deposit. 'Documents' are noted in abstract journals in the same manner as other articles. Those who desire a 'document' order it and receive it in microfilm or photoprint form.

The auxiliary publication plan has been adopted by such large-scale literature distribution operations as that of the Office of Technical Services of the U.S. Department of Commerce, which has on file more than five million pages of material, largely technical German documents, which it distributes in this manner. In the world organisation of scientific literature, it would be desirable to co-ordinate and provide interchange between auxiliary publication centres when they are established in various countries or geographical regions.

The detailed operation of auxiliary publication, applicable to original publications, translations, reference material, illustrations and tables alike, is as follows.

The editor of a journal can publish as much or as little of a technical paper as he wishes. In the case of a very specialized paper, it may be only an abstract or summary. He appends to the notice or article a note saying that the full article with diagrams, pictures, etc., can be obtained by remitting a certain price and specifying the document number under which this full article has been deposited at the central agency operating the auxiliary publication service. Orders are sent by readers directly to this central agency, which is the American Documentation Institute at Washington, D.C. Microfilms of the 'document' or, when desired, enlarged photoprints readable without optical aid are made only if and when ordered. In this way the 'document' is perpetually 'in print' but no extensive, space-consuming stocks need be stored—only the 'document' itself and the microfilm negative from which positives are made for distribution. The operation of the plan is simple and uncomplicated, and editors may use it when, how, and if they find it helpful. No financial participation or guarantees on the part of the editor or author are required. While the plan of auxiliary publication suggested could be used with other methods of duplication, microfilm is the least expensive and most universal, in that it will handle text and illustration of any sort.

MESONS AND NUCLEONS

By PROF. O. KLEIN
Institut för Mekanik och Matematisk Fysik,
Stockholms Högskolas

I SHOULD like to direct attention to an approach to the problem of the relation between mesons and nucleons, which, although speculative, seems to give a reasonable account of the main features of our present knowledge, including the fundamental work recently carried out at Bristol. The main assumptions, some of which have already been discussed by other physicists, are given below. We use the nomenclature employed by the Bristol observers for the different categories of mesons observed in photographic plates.

(1) The ordinary cosmic-ray meson (μ-meson), and its neutral counterpart, are particles of spin $\hbar/2$ with Fermi statistics. The decay of a charged meson is a true β-process, giving rise to a neutral meson, an electron and a neutrino.

(2) These particles interact by means of a Yukawa field corresponding to positively and negatively charged particles of integral spin, Bose statistics, and masses of mesonic order of magnitude. There being only charged particles of this kind, interactions of pair type will be essential. The role of these particles, and their properties, being similar to those of the photons, we may perhaps call them 'electro-photons', reserving the name meson for the particles mentioned in (1). Some σ-mesons may be of this kind, and they may be expected to occur in penetrating showers.

(3) π-Mesons, and possibly other mesonic particles of still higher mass[1], are supposed to be metastable compound systems of mesons, held together by means of the interaction mentioned above. Moreover, as a working hypothesis, we shall assume the nucleons themselves to be stable compound systems of mesons.

Having stated them, we shall now attempt a brief discussion of the arguments in favour of these assumptions, and the difficulties which they raise. Thus, in the first place, we encounter a well-known feature of any relativistic theory: the difficulty of forming a compound system with dimensions smaller than the Compton wave-length of the constituent particles. In the present instance, this length is of the same order of magnitude as the range of the forces. Dr. N. Hu has kindly pointed out to me that this difficulty is much more pronounced in an s-state than in one where the particle has an angular momentum. This may mean that a stable compound system contains only one particle in an s-state—two such particles involving a great increase in the strength of the field in which each of them moves—and, in addition, as many particles in states with an angular momentum, as is required to make the binding energy per particle as high as possible. Without a more developed theory of the interaction, it is, of course, difficult to predict how large the number of particles will be, but making use of the actual mass values of the particles in question, we may, hypothetically, regard a neutron as being built up of seventeen neutral mesons. We may assume that these particles form complete p-groups (six particles), d-groups (ten particles), and a single particle in an s-state. Of course, this classification of the separate particles according to their angular momentum is only valid in the Hartree approximation; nevertheless, it would seem to be a sufficient approximation in the present case. In order to balance the very high kinetic energy of these particles, contained in a volume of the order of magnitude $(\hbar/\mu c)^3$, where μ is a mass of mesonic order of magnitude, the forces must, of course, be much stronger than those occurring between the nucleons in the atomic nuclei. Since, however, in most nuclear force theories, a 'cut-off' procedure is applied at a distance comparable with the range of the forces, this may not require any particularly high value of the interaction constant g, but only a less violent 'cut-off'.

Suppose now that the rest mass, m_ν, of the neutral meson is 120 m_e, m_e being the electron rest-mass, a value which seems to be consistent with the conclusions of the Bristol workers. In fact, the values $m_\nu = 120\ m_e$, m_μ (mass of ordinary charged meson) $= 220\ m_e$, and m_π (mass of π-meson) $= 365\ m_e$, would correspond to a kinetic energy of the decay meson in the Bristol experiments of 4·4 MeV., and a ratio $m_\pi/m_\mu = 1{\cdot}66$. Comparing the value $17 \times 120\ m_e$ with the mass of the neutron, 1839 m_e, we obtain a binding of 100 MeV. for the neutron, a value which seems not unreasonable in view of the recent Berkeley experiments, which may perhaps be taken as an indication that nucleons can be broken up in collisions at an energy of some hundred MeV.

Since, according to the above assumptions, the decay of the ordinary meson is, so to speak, the prototype of all β-processes, it is important that the value of the life-time, $\tau = 2 \times 10^{-6}$ sec., and the energy available in the process $\sim 100\ m_e c^2$, fit in very well with the value to be expected from our knowledge of the β-decay. Let ε be the energy available divided by $m_e c^2$, and F (ε) the well-known Fermi function, which for large ε-values may be taken as $\varepsilon^5/50$. We then obtain for the product $\tau . F\ (\varepsilon)$—putting $\tau = 2 \times 10^{-6}$ sec. and $\varepsilon = 100$—the value 667, which is of about the expected magnitude. The value $\varepsilon = 100$ would also seem to be consistent with the energy values indicated by the small number of cloud-chamber pictures of decaying mesons. (The above considerations were essentially stimulated by a communication kindly made to me by Prof. J. Blaton in connexion with an interesting attempt to regard the π-meson as a compound system of a neutral and a charged meson. In this approach, the component particles were supposed to be of integral spin, and kept together by forces of the original Fermi type, corresponding to an interaction by means of electron-neutrino pairs. It was then found that the interaction constant corresponding to the meson life-time is of the same order of magnitude as that to be expected from Fermi's original theory of β-disintegration, a result which is, of course, identical with that of the above calculation; see also Konopinski[4].)

Proceeding now to the proton, we shall again assume a system of seventeen particles, but with a unit charge. Owing to the strong interaction with the Yukawa field, this charge would probably belong to the whole system rather than to any individual meson. Keeping in mind that the charged meson is about 100 m_e heavier than the neutral meson, the question arises how this difference can be more than compensated in the compound system, so as to give the observed difference in mass of the proton and the neutron. A possible explanation may be that the interaction corresponding to an exchange of a single electrophoton, in the interaction between unlike particles, has to be added to the pair interaction in the case of like particles. An estimate of the constant g of this interaction, required to compensate the mass difference in question, is seen to give a very reasonable value of the order of magnitude of the electronic charge. In fact, since the size of a nucleon is probably of the order of magnitude of, or even smaller than, the range of the forces in question, we may estimate this effect by considering the decrease of potential energy of a sphere of N particles each of electric charge g, to which a particle of charge $-g$ is added. This, now, will be equal to $\frac{3}{5}\cdot\frac{(2N+1)}{a}g^2$, if a is the radius of the sphere. With $N = 16$, we obtain thus the following approximate relation

$$\frac{3}{5}\cdot\frac{33g^2}{a} \simeq 100\, m_e c^2 = 100\,\frac{e^2}{a_0},$$

where a_0 is the radius to the electron; or, $g^2 \simeq 5\,\frac{a}{a_0}\,e^2$. From the well-known sizes of atomic nuclei, we get, as an upper limit to the value, $1{\cdot}2 \times 10^{-13}$ cm.; while $a_0 = 2{\cdot}8 \times 10^{-13}$ cm.; and thus $g^2 \lesssim 2e^2$.

The problem of the capture by nuclei would, of course, be a rather different one for the mesons and for the electrophotons. The latter particles would probably behave in accordance with the theories developed along the lines of Yukawa's original ideas, mesons taking now the role of nucleons. On the other hand, the former particles may either be captured in a way somewhat analogous to the K-capture (similar to suggestions put forward by Pontecorvo and Weisskopf[2]), with the emission of a neutral meson and a neutrino pair; or in an annihilation process of the Dirac type. As Dr. B. Bruno has kindly pointed out to me, this latter process will have a considerable probability, a point to which he hopes to return in connexion with a study of the problem of meson capture.

As to the Yukawa particles or electrophotons, their relation with the meson being similar to that of mesons and nucleons in the current meson theories, we should expect to observe their creation by *Bremsstrahlung*—in processes, for example, such as the impact between fast nucleons or mesons. Moreover, we should expect that mesons could be created in pairs by electrophotons as well as by photons of high energy, a phenomenon which may, perhaps, play a part in the penetrating showers. On the other hand, collisions between fast particles and nuclei may lead to the break-up of nucleons, whereby metastable compound systems like the π-meson may be formed. In such processes we should expect an excess of positive particles, although negative particles of this kind are perhaps not excluded, owing to the strong interaction of the mesons with the electrophotons. Nevertheless, we should expect the positive and negative mesons, like positrons and electrons, to be separated by an energy gap equal to twice the rest-mass energy. Just as the ordinary neutron is closely connected with the positive proton only, we should expect that there would be two kinds of neutral mesons, connected with the positive and the negative mesons respectively, which would probably have magnetic moments of opposite sense relative to the spin.

As regards the problem of the interaction of nucleons, the above considerations would imply some modifications of the theory by the introduction of a natural radius of a nucleon; that is, a strong repulsion when the distance between the nucleons gets below a certain value, $\simeq 10^{-13}$ cm. This may have some consequence for the scattering problem, as well as for the problem of the saturation of nuclear forces. Further, if a nucleon is a compound system of some seventeen particles, the value of the interaction constant for the force between two nucleons will have a less fundamental significance than in the ordinary meson field theory. Since the Yukawa theory of β-radioactivity would have to be applied to the mesons interacting with electrophotons, we shall expect the life-time of the latter particles to be considerably shorter than that of the mesons, which may account for the lack of evidence for the existence of these particles. It would perhaps be worth while, however, to consider the possibility that the large spread of the mass values obtained for the cosmic ray mesons may be partly due to some of the measured particles being electrophotons. In an attempt to regard the nuclear field force theory as a generalization of the relativistic field theory of electromagnetism and gravitation, I obtained the following expression for the rest mass μ_e of a charged Dirac particle, as compared with the rest mass of the corresponding neutral particle μ_n:

$$\mu_e = \sqrt{\mu_n^2 + \mu^2},$$

where μ is the mass of the electrophoton[3]. Apart from the ambiguity still present in the basic assumptions, this formula neglects possible self-energy effects on the masses of the particles. Still, it is interesting that, with the above values for μ_e and μ_n, it gives a reasonable value for μ, namely, 185 m_e.

According to the view developed here, the building up, as well as the destruction in any appreciable amount, of nucleons would require conditions differing even more from those prevailing in the known parts of the universe than those necessary for the building up and destruction of nuclei. Thus an equilibrium in which there is a considerable dissociation of nucleons into mesons would seem to require a temperature corresponding, at least, to $kT \simeq 100$ MeV. At this temperature, the mass density of meson pairs, as calculated from the ordinary Fermi distribution formula, would approach that in the interior of an atomic nucleus.

In concluding these remarks, it may be stressed that owing to the strong assumed interaction between mesons and electrophotons, and the size of the Compton wave-length as compared with the range of the forces, we are at the extreme limit of the region where it is permissible to speak about systems built up of individual particles. Although this would suggest that great caution should be observed in the handling of the problem, it would not seem, *a priori*, to make fruitless an attempt such as that under consideration.

Note added to proof. Since the above was written, definite evidence has appeared in favour of a mass value $\sim 300\ m_e$ for the σ-mesons; their production in the Berkeley experiments and their star-producing capacity making it, moreover, very probable that they are the true Yukawa particles or electrophotons. Their assumed identity with the π-mesons, which, if correct, would necessitate important alterations of the hypothetical postulates put forward in the above note, seems to me less evident, however; and it is perhaps not out of place to discuss the consequences of the opposite assumption in the light of the new results.

Thus it would seem natural to assume the mass m_σ of the σ-meson to be smaller than $m_\nu + m_\mu$, the sum of the masses of the two μ-mesons, charged and neutral; while m_π, the mass of the π-meson, would have to be greater than $m_\nu + m_\mu$. Using the values of the above example, we should have $m_\pi > 340\, m_e > m_\mu$, an inequality which does not seem contradictory to present experience. While on this assumption the σ-meson could not spontaneously give rise to a pair of μ-mesons (charged and neutral), such a process would be possible in the field of a nucleus, if the energy is sufficient—as it might easily be under the Berkeley conditions. It is suggested that this may be the explanation of the comparatively large number of μ-mesons observed in the Berkeley plates. While the most probable process under those conditions seems to be the formation of σ-mesons by *Bremsstrahlung*, the observed cases of π-decay might on the above view be due to a break-up of nucleons, a process which would be expected to occur with measurable probability, the energy quantum (frequency multiplied by Planck's constant), corresponding to the collision time, being of the same order of magnitude as the assumed binding energy of the nucleon.

Without entering more closely on the consequences of the opposite assumptions—the identity of σ- and π-mesons—for the above considerations, I should like to state that in my view the interpretation of the μ-meson as an $\hbar/2$-particle with an ordinary β-decay, which is, of course, independent of the hypothesis concerning nucleons and π-mesons, has not only a better foundation than the other assumptions of the above note, but also the more important bearing on the problem of the incorporation of meson theory in the general relativistic field theory. In this connexion it should perhaps be mentioned that the argument given in the note concerning the mass value of the electrophoton can only be expected to give the order of magnitude.

EXCITATION CURVES FOR THE γ-RADIATION FROM LIGHT ELEMENTS BOMBARDED WITH α-PARTICLES FROM POLONIUM

By Prof. HILDING SLÄTIS
Nobel Institute for Physics, Stockholm

A LARGE number of investigations have been carried out on the disintegration of light nuclei bombarded with α-particles. In several cases excitation curves have been obtained for the γ-radiation as a function of the energy of the α-particles. (A review of earlier polonium α-particle bombardments of light elements, particularly those which may be of interest for a possible γ-radiation, has been published by the present writer in *Arkiv. Mat., Ast. Fysik*, 35 A, No. 31 (1948). The results of different authors, however, are often inconsistent. For that reason I made use of an available polonium sample of about 40 mC. for observing the excitation functions of the γ-radiation from light elements bombarded with α-particles. The energy of the α-particles was varied by means of carbon dioxide.

Lithium, beryllium, boron, carbon, nitrogen, oxygen, fluorine, sodium, magnesium, aluminium, silicon, phosphorus, sulphur, chlorine, potassium, calcium and lead were investigated. γ-Emission was observed from lithium, beryllium, boron, nitrogen, fluorine, sodium, magnesium and aluminium. The intensity of the γ-radiation was measured as a function of the energy of the α-particles for all these except nitrogen (Figs. 1–2). The α-particle threshold values for γ-emission and the relative intensities (as percentage of the measured polonium γ-radiation background) of the γ-quanta are given in the accompanying table.

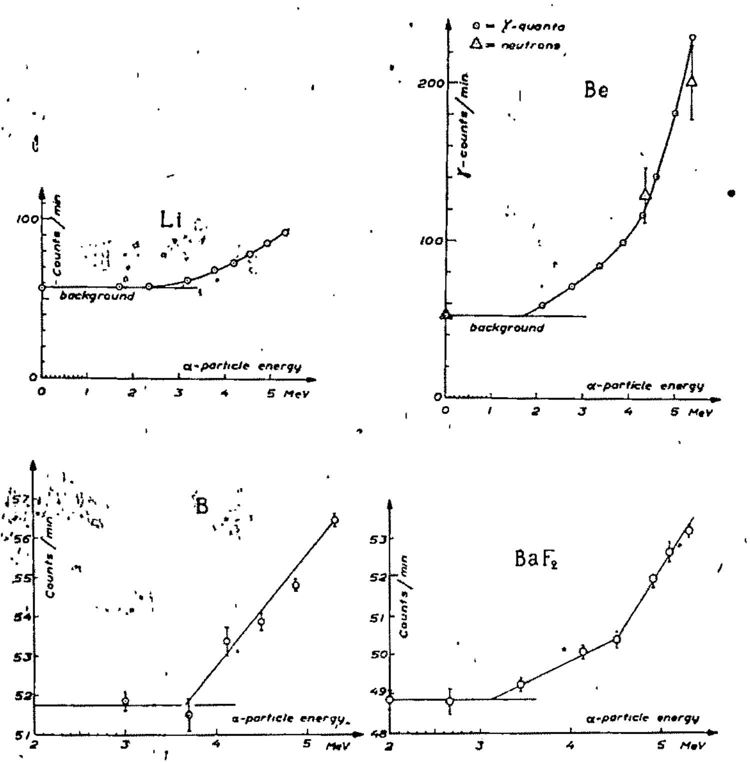

Fig. 1. Emission of γ-quanta (⊙) from lithium, beryllium, boron, fluorine, and neutrons (△) from beryllium as a function of the energy of the bombarding α-particles

Element	γ-Emission starts at the α-energy	Intensity of the γ-radiation for 5·3 MeV. α-particles
	MeV.	
Li	2·3	61
Be	1·7	340
B	3·7	9·0
N	—	2·7
F	3·1 (and 4·5)	9·0
Na	4·6	9·5
Mg	3·6	3·7
Al	4·1	7·9

The statistical errors are represented in all the diagrams except the γ-emission curves for lithium and beryllium, where the errors were too small to be

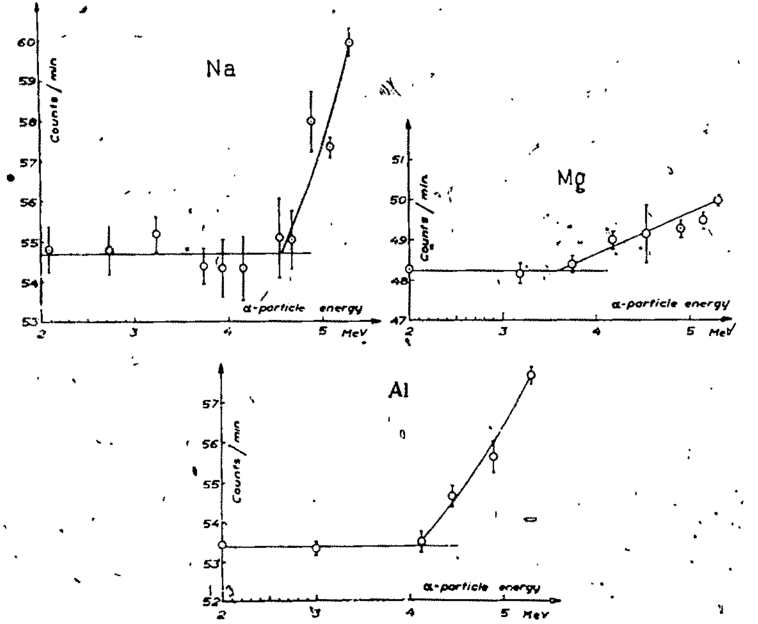

Fig. 2. γ-EMISSION FROM SODIUM, MAGNESIUM AND ALUMINIUM AS A FUNCTION OF THE ENERGY OF THE BOMBARDING α-PARTICLES

plotted ($\lesssim$ 1 per cent of the polonium γ-radiation background).

The neutron-emission from beryllium was measured for α-particles of energies 4·3 and 5·3 MeV. The results and the statistical errors are plotted on an arbitrary scale in Fig. 1.

$_3$Li. The γ-radiation is due to an excitation of the Li^7-nucleus by inelastic collisions with α-particles, as quoted, for example, in the paper by Siegbahn and Slätis[1]. The γ-radiation starts for α-particles of the energy 2·3 MeV., in agreement with the result of Schnetzler[2] but not with earlier investigations by Webster[3] (1·9 MeV.), Curie and Joliot[4] (3·1), Savel[5] (2·8–3·0).

$_4$Be. The γ-radiation maximum with 2·7 MeV. α-particles found by Becker and Bothe[6] could not be confirmed, nor the starting point of the γ-emission for α-particles of the range 1·7 cm. (3 MeV.). The neutrons seem to be emitted simultaneously with the γ-quanta, as predicted by Chadwick[7]. The energy (1·7 MeV.) of the α-particles at which the γ-emission starts is the same as Chadwick found for the beginning of the neutron emission, and is in fairly good agreement with the starting points for the γ-emission found by Webster[3] (1·9 MeV.) and by Szalay and Zimonyi[8] (1·62 MeV.). Rasetti[9] found 1·6 MeV. for the beginning of neutron emission and Curie and Joliot[4] 1·3 MeV. for neutrons and γ-quanta.

$_5$B. According to Becker and Bothe[6], the γ-radiation begins at the same α-particle energy for which the second proton group starts (also in agreement with v. Baeyer[10]). The corresponding α-particle range was 2·90 cm. (4·4 MeV.). This is not in agreement with the curve in Fig. 1, which starts at 3·7 MeV., or with the results of Webster[3] (1·9 MeV.), or those of Szalay and Zimonyi[8] (1·5 cm. = 2·7 MeV.), but in good accordance with Heidenreich[11] (3·6 MeV.) and Alichanow, Alichanian and Dzelepow[12] (2·1 cm. = 3·5 MeV.).

$_9$F. The first proton *pair* found by Chadwick and Constable[13] started at an α-range of 2·2 cm. (3·64 MeV.), the second pair at 2·7 cm. (4·2 MeV.). This result is not in agreement with my observations; I find that (Fig. 1) the γ-radiation starts at 3·1 MeV. with clearly a second component at 4·5 MeV. energy of the α-particles. The starting point 0·9–1·2 MeV., found by Savel[5], seems to be very improbable. Speh[14] discovered that the γ-radiation consisted of two components. The harder one started at 3·1 cm. α-particle range (4·6 MeV.), which is in good agreement with the second starting point of the γ-radiation shown in Fig. 1.

$_{11}$Na. According to Fig. 2, γ-emission starts at an α-particle energy of 4·6 MeV. This agrees neither with Savel's[5] result (3·7–4 MeV.) nor with Kovács's[15] (2·7 MeV. and 3·5 MeV.). König[16], however, found a proton resonance group, called *B*, which started at 4·8 MeV. This is in accordance with my result.

$_{12}$Mg. Klarmann's[17] first proton group started at an α-particle energy of 3·26 MeV., which may agree with my value 3·6 MeV. for the beginning of the γ-radiation (Fig. 2). Savel[5] found 4·3–4·5 MeV.

$_{13}$Al. Pose's[18] first proton group for an α-range of 2·50 cm. (4 MeV.) agrees well with the α-particle threshold value 4·1 MeV. for the γ-emission found by me (Fig. 2). Chadwick and Constable[13] found for the first proton pair a threshold value 4·2 MeV. for the α-particle energy, also in good accordance with my result. Savel[5] found 3–3·3 MeV. for the beginning of the γ-emission, Fahlenbrach[19] 3 cm. (4·5 MeV.) for the starting point of the (α, p)-process, Alichanow, Alichanian and Dzelepow[12] 3·4 cm. (4·9 MeV.) for the (α, n)-process. For the same (α, n)-process Waring and Chang[20] obtained 3·4 MeV. Pollard, Schultz and Brubaker[21] found possible resonance effects at 2·3 cm. (3·8 MeV.) and 4·8 cm. (6 MeV.). The former α-particle energy 3·8 MeV., as well as Fünfer's[22] value 2·3 cm. (3·8 MeV.) and the starting point 2·4 cm. (3·9 MeV.) for the γ-radiation, found by Szalay and Zimonyi[8], agree well with my α-particle energy value 4·1 MeV. for the beginning of the γ-radiation from aluminium.

REACTIVITY AND STRUCTURE OF MOLECULES

AN International Colloquium on Isotope Exchange and Molecular Structure was held in Paris during April 5–12 under the presidency of Mme. Joliot-Curie. It had been organised, with the support of the Rockefeller Foundation, by three French scientific workers well known for their contributions to these subjects, R. Daudel, M. Haïssinsky and P. Süe. About a dozen speakers had been asked to read papers; others had been invited to contribute to the discussions. A somewhat unusual feature was the friendly insistence by the organisers on French as the only 'official' language; but as the Paris colleagues had taken the trouble of translating papers before the congress started, all foreign authors bravely presented them in the language of their hosts. During the discussions most of them preferred to express, or to hear, the arguments in their mother tongue; this caused no difficulty, as good linguists were always present and willing to act as interpreters. (One of the most competent translators sometimes even quietly amplified what had actually been said by a speaker.) A further help was the distribution of the manuscripts in their original tongue to all the participants.

The discussions were lively and inspiring; they will be printed in full, together with the addresses, in *Le Journal de Chimie et Physique*. We shall confine ourselves here to a brief summary of the papers.

Although the main subject of the colloquium was the connexion between the structure of a molecule and its ability to take part in isotopic exchange processes, several of the papers dealt only with questions either of structure, or of exchange, leaving the conclusions to be drawn to the discussion or to further investigations. A contribution to the subject in its strict sense was the opening address by Prof. L. Pauling (Pasadena) on "Structure of Complexes and the Influence of Structure on Exchange Reactions"; according to his calculations, the replacement of one group in a complex molecule by another may occur readily if the co-ordination number of the complex is smaller than the maximum permitted by steric considerations. To the same group belonged the papers by P. Süe and G. Kayas (Paris) on "The Behaviour of some perfect Cobalt Complexes in Szilard-Chalmers Reactions"; by B. Pullman, P. Rumpf and F. Kieffer (Paris) on "Isotopic Exchange Reactions and Electronic Structure of Substituted Aromatic Hydrocarbons"; and by C. K. Ingold (London) on "Isotope Exchange and the Mechanism of Heterolytic Substitution". A theoretical paper on "Free Valence in Organic Reactions" was read by Prof. C. A. Coulson (London).

Prof. C. D. Coryell (Boston, Mass.) discussed the results of studies carried out in the Clinton Laboratories on the valency states of the elements selenium, tellurium, bromine, iodine and cerium, if produced by nuclear transformations and present only in tracer concentrations; he pointed out that the results are not yet numerous enough to offer themselves for broad generalizations. It is likely that each element will show peculiarities which can only be explored by detailed studies. An example of such an investigation of a single case was given by P. Süe in his work on the ions formed in sodium arsenite, sodium arsenate and sodium cacodylate under the impact of neutrons; it seems that in these reactions the lower valency state is favoured.

M. and Mme. Daudel, in collaboration with S. May, R. Muxart and O. Chalvet (Paris), presented a paper on "The chemical reactions which are the consequences of those nuclear reactions which do not change the nature of the element". Such a nuclear reaction may consist either in the absorption of neutrons with emission of γ-rays, or in a nuclear isomerization; in the first case the observed chemical reactions are easy to foresee as following from the production of free, fast-moving atoms; the chemical effects of isomeric nuclear changes have to be interpreted by a mechanism involving the re-arrangement of the electrons in the atom concerned. E. Broda (Vienna) discussed the various methods available for the determination of the yield of nuclear reactions of the (α, *n*) type; he showed that the Szilard-Chalmers effect of the emitted neutrons offers certain advantages over the alternative methods of the ionization chamber or photographic plate. In a second paper he discussed the phenomenon of 'retention' of activity in cases where one would expect the Szilard-Chalmers effect to give complete separation of the active atoms.

Two of the contributors dealt with heterogeneous exchange reactions. M. Haïssinsky (Paris) described experimental investigations carried out, together with M. Cottin and B. Varjadebian, on exchange between metal electrodes and their ions in solutions. Their object was to compare the exchange rates with the electrochemical potentials of the metals, taking into account also the possible effect of temperature, concentration, acidity, mechanical state of the surface, and all the other factors which may be of influence on exchange rates. The authors consider the imposing experimental material they have collected only as the beginning of further researches necessary for the full understanding of the exchange mechanism. In a second paper, M. Haïssinsky examined in a critical way the possible connexions between the exchange processes on the surface of the electrode and various electrochemical phenomena; he found that his experiments support Piontelli's distinction of two classes of metals. The other paper on heterogeneous exchange was read by F. A. Paneth (Durham). The exchange of ions between solution and crystal surfaces has, since 1923, often been used as a method for the determination of the extent of the surface area. In reviewing published and a few unpublished experiments, he has come to the conclusion that the exchanging part of the surface may be much smaller than the geometrical surface, but at the same time the only important one for the phenomena of adsorption and catalysis, and therefore well worth studying. This view was supported by Prof. M. Prettre (Lyon). Furthermore, the measurement of the equilibrium between ions in crystal surfaces and non-isotopic ions in solution may help to an understanding of the precipitation reactions of tracer elements without isotopic carriers.

The unfortunate absence of the authors did not diminish the interest taken in the papers by C. C. Evans and S. Sugden (London) on "Exchange Reactions and Electrolytic Dissociation", and by M. D. Kamen, J. W. Kennedy and O. E. Myers (St. Louis) on "Kinetic Studies on Isotopic Exchange Reactions" (both read by M. Haïssinsky), but naturally restricted the possibilities of a discussion.

At the end of the last session, before the concluding words of Mme. Joliot-Curie, Prof. G. v. Hevesy (Stockholm) summed up the proceedings by giving a brief résumé of all the contributions. During a break in the meetings the guests were given the opportunity of visiting the Laboratoire de Physique Nucléaire under the guidance of its director, F. Joliot (who was also an occasional contributor to the discussions), and the French Government's Atomic Energy Establishment at Châtillon, where preparations are far advanced for the erection of a heavy water–uranium oxide plant, and an impressive array of counting equipment of all types is being produced. Châtillon is an old fort in the outer defence girdle of Paris, and the skill with which the dark subterranean rooms have been converted into modern laboratories deserves admiration.

The last day of the congress was free from lectures and offered good opportunities to continue some of the discussions in smaller circles before the final dispersal of the participants of a very successful international meeting. F. A. PANETH

FAUNA AND FLORA OF PALESTINE

PALESTINE'S fast diminishing larger fauna is bound to suffer from the Jewish–Arab war; many species of great historic interest may be exterminated, and several, like the gazelle, the geographical races of which have not yet been fully worked out by the modern zoologists in the country, may be among them. Attention was directed to the serious reduction in the numbers of the larger mammals by modern 'hunters' in special surveys reported in the bulletins of the Jerusalem Naturalists' Club in 1946. The difficulty of human food supplies will be a serious threat to the remaining numbers of ibex already on the verge of extinction in the country; and the departure of the Palestine Police Force which alone enforced the British-made game laws—these prohibited the shooting of ibex, eagles, vultures, kestrels, owls, etc., and imposed certain close seasons and preserved certain forests against goat-grazing—will leave unrestricted the activities of 'hunters' and others. The grazing of these reserves by Beduin goatherds will have a serious effect upon plant life, for the ubiquitous goat is one of the most serious destroyers of flora in the country and a contributory factor to the costly menace of soil erosion.

Bab el Wad, which has been the scene of many recent news reports of a battle on the Jaffa–Jerusalem road, is a pine forest planted by the British authorities, twenty-four kilometres below Jerusalem. It consists mainly of *Pinus halepensis* and a large summer flora including *Varthemia*, *Centaurea cyanoides*, *Helichrysum sanguineum*, *Cistus vilosus*, *Acanthus syriacus* and many Labiates (Bull. 25, Jer. Nat. Club, p. 4), while W. F. W. Harding and E. Hardy collected and photographed in the forest the interesting amaryllid, *Pancratium parviflorum*, and *Narcissus Tazetta*, the Palestine iris, and various *Crocus*, *Cyclamen*, etc. (*J. Roy. Hort. Soc.*, 71, 3; 1946).

The bird-life of Palestine, like the mammals, may see the most immediate threat since the removal of law and order to the larger birds of prey; but the netting of quail, suppressed by the British authorities, will probably be resumed for food, together with the unrestricted shooting of the many wildfowl that visit Lake Huleh and the Jordan Valley. The nightjar is among the birds recorded at Bab el Wad in Hardy's 1946 "Handlist of the Birds of Palestine", and this work pointed out that the great bustard, the Egyptian goose and the Syrian ostrich are already extinct in the country, and the white stork, the lammergeier, the imperial eagle and the white-faced duck no longer nest there.

Among the more immediate threats to bird-life in the present emergency will be that to the nesting colony of purple herons at Lake Huleh, the young of which are eaten as food by the Arabs. Other scarce birds likely to be sought to augment the food supplies are the houbara or Macqueen's bustard of the southern and Jordan deserts, which no longer nests in the country, the red-billed chukor partridge of the central hills and the Hey's sand partridge of the semi-deserts. Quail-catching and the shooting of song-birds for food will probably assume the large extent they already reach in Syria. The Hebrew University has shown an active interest in plant and bird conservation, and they and the Arab Scout movement and several private individuals were active supporters of the efforts made by the now defunct Jerusalem Naturalists' Club to conserve the rapidly diminishing fauna of the Holy Land during the last few years of the British mandate, especially at Lake Huleh and in the Jordan Valley; but with the lifting of the central authority, it is to be feared that animal life will suffer from the extensive use of rifle and poison before law and order restore close seasons, game reserves and the control of fire-arms, which are essential if the large mammals like the leopard, ibex, wolf, cheetah and gazelle are to survive.

AFFORESTATION AS A WORLD PROBLEM

IN a brochure entitled "Forestry and Forest Products—World Situation 1937–1946", issued by the Food and Agriculture Organisation of the United Nations, a graphic exposition of the world's position was produced (see *Nature*, May 8, p. 710). Prof. H. G. Champion, professor of forestry, University of Oxford, also discussed this theme in a paper entitled "Afforestation as a World Problem" before the Royal Society of Arts on March 17. In this paper he discussed various aspects of forestry and forestry work. As he correctly says, "the majority of us pay little attention to the changes which have taken place in the past in the natural vegetation which covers most of the land not taken up by buildings, roads, gardens, mines or agricultural crops. We are barely conscious of the fact that in Britain almost every acre of cultivation and bare land—except on the hill tops and in the fens—has been cleared from the forest which once covered nearly the whole surface. From being a country almost entirely under forest, England has now a lower proportion than any other country in Europe." How often did a predecessor of Prof. Champion's at Oxford, Sir William Schlich, point this out to a deaf Government?

The respective positions of Western European countries, as shown by figures given by the Food and Agriculture Organisation, are contrasted. The interesting position of the Middle East, contrasted with its position in Biblical and Roman times, is discussed; also that of America, Central and South Africa and Australia. Here the picture is chiefly one of ruthless destruction of the forests, either in the interest of agriculture or stock raising, or due to the habits of the local and introduced populations of annual unchecked firing of the countryside for whatever purpose, and over-grazing. Such actions have produced serious conditions in temperate climates. In the tropics they are devastating. For example, Prof. Champion states that in Nigeria it has been estimated that 1,000 square miles of forest are being destroyed by shifting cultivation annually. This type of affairs is proceeding throughout many parts of Africa in British, French, Belgian and Portuguese Colonies. The author contrasts the nature of the vegetation which may clothe the soil when the forest is removed "if, indeed, the soil does get or retain a cover at all". Temperate and tropical conditions are dealt with. Prof. Champion particularly stresses grazing of domestic cattle and the damage caused. "In all but the wet tropical forests, grazing is liable to be second only to direct human action as a forest-destroying agency", a statement which must be known now throughout the world, though still requiring emphatically re-stating. Protection of endangered existing forest areas by closure, re-afforesting and so forth are the remedies which are imperative in many parts of the world.

As the report of the Food and Agriculture Organisation stressed, production is not the only aim of the forester. Indirect effects of the presence of the forest on a countryside are also aimed at, and one of the vital ones is protecting the forest or rebuilding a forest to check erosion, shelter agricultural lands and stock and so forth, and the protection of all water catchment areas, including the head waters of streams and rivers.

Finally, Prof. Champion considers the immediate objectives of the larger afforestation undertakings of the world under seven heads: briefly, stabilization of moving sands, increasing local supplies of timber and fuel, stoppage of erosion on hillsides through avalanches and of areas on hills liable to ravine formation, protection by forests or woodland belts of agricultural land and stock and buildings, re-afforesting of waste land and growing timber to supply industries for export trade or to maintain or build up stocks at home. These are discussed in some detail in the paper.

SOUTH AFRICAN COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

THE second annual report of the South African Council for Scientific and Industrial Research (Block 1, Central Mint, Pretoria) covering the year ended October 5, 1947, refers to progress in establishing the Council's national laboratories and services as exceeding expectation in many respects, although it will still be several years before all are fully working. Four industrial research associations, covering the leather, fish, paint and sugar-milling industries, are now in being and proposals for a fifth, to deal with the clay and ceramic industries and others interested in silicates, are being discussed. During its first two years the Council has signed contracts for twenty investigations for industrial and other sponsors to a value of £13,968, and of these seven have been completed. Arrangements for the support of research in universities and similar institutions operated satisfactorily during the year, but it is probable that the Council will have to consider further means of assisting the universities to provide the large number of scientific men and women of high qualifications which will be required.

The work of the Library and Information Division increased greatly during the year. The Library now includes about 70,000 books, pamphlets and reports on all branches of science and technology. A draft guide to authors in the preparation of abstracts has been prepared for the use of South African scientific periodicals the abstracts of which will be distributed overseas. The functions of the three main divisions of the National Building Research Institute have been more sharply defined, and sub-division of the Engineering Division into three sections—engineering, materials, and soil mechanics—is already visualized. The services of the soil mechanics section are already in embarrassing demand. Details of some forty-two projects in which work is already proceeding are given in the report, and among these may be mentioned foundation design for small houses, soil-cement construction, a study of expansive mortar failures in brickwork, standardization of wear-test for flooring, termite-proofing of buildings, comfort standards, tests for the thermal properties of building materials, roof ventilators, ventilation and natural lighting of buildings and a study of native housing.

Considerable progress has been made with the National Physical Laboratory, where the Spectrographic Section has made a satisfactory start. Work has already been commenced on the design and construction of instruments for aptitude testing, the measurement of soil pressures, the use of supersonic waves as a bactericide and on general acoustics. The Telecommunications Research Laboratory has measured and studied the characteristics of the ionosphere, and work on the measurement of radio noise-levels was contemplated. Measurements have been made of the propagation of radio waves in the Witwatersrand gold mines, and a micro-wave radar set has been developed for tracking thunderstorms. At the National Chemical Research Laboratory, the Microbiological Section, working at the Onderstepoort Laboratories, has investigated new yeast-like organisms from the rumen ingesta of sheep, and work is proceeding on the determination of degradation products arising from the action of moulds on wattle tannin extract. The fats, waxes, and proteins unit has been concerned with investigations on pilchard oil, the vitamin A content of liver oil from soupfin sharks and on marine fats.

Under the National Bureau for Personnel Research, the three main projects have covered selection and classification tests for operatives in the clothing industry, classification tests for native miners and 'boss-boys', and personnel research for the Union Defence Force. The development of screening and aptitude tests for the engineering branch of the G.P.O. continued during the year. A Liaison Division was formed during the year to provide liaison between the Council's laboratories and industry, including the handling of technical inquiries, visits to industrial firms and the organisation of co-operative research in industry. This Division is also responsible for handling contracts for sponsored research and the overseas scientific liaison offices and missions.

Seven senior bursaries or fellowships were awarded by the Council during the year to enable South Africans of outstanding ability and experience to carry out at least a full year of unencumbered research. Three senior bursaries were also awarded for research in the medical field, and details of these ten awards are given in the report. Twelve bursaries of £200 a year were also awarded for postgraduate research and five others for postgraduate medical research, and eighteen bursaries of £100 a year to undergraduate research students.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, June 7

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 8.15 p.m.—Dr. T. Paterson: "Explorations in the Canadian Arctic".

Tuesday, June 8

Research Defence Society (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 3.15 p.m.—Annual General Meeting: Prof. P. A. Buxton, F.R.S.: "Tsetse Flies and the Development of Africa" (Seventeenth Stephen Paget Memorial Lecture).

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.2), at 5 p.m.—Prof. Pie Laviosa Zambotti: "The Origin and Diffusion of Civilization".

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

Wednesday, June 9

Physical Society, Colour Group (at the Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 3.30 p.m.—Mr. R. W. G. Hunt: "The Effects of Daylight and Tungsten Light Adaptation on Colour Perception".

Institute of Petroleum (at 26 Portland Place, London, W.1), at 4 p.m.—Scientific Papers.

Manchester Statistical Society (at the Reform Club, King Street, Manchester), at 5.30 p.m.—Annual General Meeting.

Thursday, June 10

Chadwick Public Lecture (at the Chelsea Physic Garden, Swan Walk, London, S.W.3), at 4 p.m.—Prof. Frederick G. Gregory: "The Factors Controlling Reproduction in Plants".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. V. B. Wigglesworth, F.R.S.: "Insects as a Medium for the Study of Physiology" (Croonian Lecture).

Friday, June 11

Fertiliser Society (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 2.30 p.m.—Dr. W. G. Ogg: "Fertilisers in the National Economy".

Physical Society, Optical Group (in the Physics Department, Imperial College of Science, Imperial Institute Road, London, S.W.7), at 3 p.m.—Mr. T. Smith, F.R.S.: "The Computation of Large Numerical Aperture Telescope Objectives"; Prof. L. C. Martin: "The Boundary Wave Theory of Image Formation".

Saturday, June 12

British Psychological Society (in the Hastings Hall, Tavistock House, Tavistock Square, London, W.C.1), at 2.30 p.m.—Prof. A. B. Fitt: "Is Development Affected by the Season of Conception?"

Institute of Physics, Electronics Group (at the London School of Tropical Medicine and Hygiene, Keppel Street, London, W.C.1), at 2.30 p.m.—Discussion on "Substances of High Permittivity".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (Grade III) in the Department of Chemistry, with special qualifications in inorganic and physical chemistry—The Clerk, Birkbeck College, Breams Buildings, London, E.C.4 (June 12).

Lecturer in Civil Engineering—The Registrar, The University, Leeds 2 (June 14).

Soil Survey Officers in the Gold Coast to supervise the collection of information about the soils of the forest region in that territory—The Director of Recruitment (Colonial Service), Colonial Office, 15 Victoria Street, London, S.W.1 (June 15).

Agriculturist in the Southern Rhodesia Government Service—The Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (June 15).

Lecturers in Physics, Zoology, Botany, Chemistry and Mathematics, in the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (June 15).

Demonstrator in the Department of Zoology—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (June 18).

Assistant Technical Officers (temporary) in the Agricultural Lime Department of the Ministry of Agriculture and Fisheries—The Ministry of Labour and National Service, Technical and Scientific Register, Section K, York House, Kingsway, London, W.C.2, quoting G.186/48A (June 21).

Lecturer in Plant Physiology, a Lecturer in Mathematics, and a Lecturer in Botany (Bacteriology)—The Registrar, University College of South Wales, Cathays Park, Cardiff (June 21).

Assistant Poultry Officer (male), in the Department of Agriculture and Lands, Government of Southern Rhodesia—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (June 23).

Lecturer in Mathematics in the United College, St. Andrews—The Secretary, The University, St. Andrews (June 30).

Lecturer in Physical Chemistry, and a Lecturer in Physiology, in University College, Dundee—The Secretary, The University, St. Andrews (June 30).

University Lecturer and University Demonstrators (2) in Chemical Engineering—The Secretary, Appointments Committee of the Department of Chemical Engineering, Chemical Laboratory, Cambridge (July 1).

Leverhulme Research Studentship for research into some aspect of the history or archæology of London—The Secretary, London Museum, Lancaster House, St. James's, London, S.W.1 (July 1).

Lecturer in Mechanical Engineering in the University of Melbourne—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 1).

Professor of Mechanical Engineering, and a Professor of Botany, at the University of the Witwatersrand, Johannesburg—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 31).

Soil Analyst in the Soil Survey Branch of the Agricultural Department of the Gold Coast—The Director of Recruitment (Colonial Service), Colonial Office, 15 Victoria Street, London, S.W.1.

Assistant and Associate Professorships in the Department of Physics—The Head, Department of Physics, University of British Columbia, Vancouver, B.C., Canada.

Junior Laboratory Technician in the Pathology Laboratory—The Secretary, Marie Curie Hospital, 66 Fitzjohn's Avenue, London. N.W.3.

Field Officer by the East Africa High Commission in the Interterritorial Tsetse Reclamation Department—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.21363/3F.

Young Engineer or Science Graduate to assist in the administration of research programmes on the manufacture and use of wrought steel—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, endorsed 'Wrought Steel'.

Demonstrator in the Department of Chemistry—The Registrar, University College, Singleton Park, Swansea.

Laboratory Technician in the Department of Chemistry—The Secretary, University College, Gower Street, London, W.C.1, quoting Chemistry/4.

Metallurgist for investigation of problems in welding of structural alloy steels—The Director of Research, British Welding Research Association, 29 Park Crescent, London, W.1.

FOOD PRODUCTION AND LAND UTILIZATION

A DANGEROUS situation appears to be developing in world food production. Almost everywhere populations are increasing, and in many regions the area of land available for food production is shrinking: agriculturists are being faced with the problem of producing more and more food from less and less land. The population of England and Wales has gone up by about 14 millions since 1891, but the area of land under field and crops has shrunk by nearly 4 million acres. We now have little more than half an acre of cultivated land per head of population, and it required about 1·6 acres per head to produce the pre-war dietary. Our present reduced scale of feeding, with its cut of about 20 per cent of calorie supply, calls for less land per head, but even so we are producing on our present acreage only 40 per cent of our food. And the area of cultivated land still shrinks: housing estates, road widening, surface mining, demands of the Services and other activities absorb much land and often spoil more. Of the land still left in cultivation, little more than half can be called good; the rest is only moderate, and although we still have some reserve of potentially utilizable land, the cost of reclaiming it and keeping it in cultivation would be high, often very high. At the present rate of loss, we shall be fortunate if technical advances in agriculture enable us to continue producing as much as 40 per cent of our food, unless the public will tolerate a lower dietary.

So long as Britain was the chief buyer in the world's food markets, we had a considerable voice in fixing the price; but there are now other buyers, and the commercial arrangements are different; prices have moved against us and may rise still further. Europe (excluding the U.S.S.R.) was formerly almost self-supporting in food, importing less than 10 per cent of the grain consumed and having a small net export of meat and dairy produce. Now, however, the position is entirely different: the import requirement of grain is more like 20 million tons to satisfy the reduced—in many cases drastically reduced—rations now available. In so far as this situation is due to war devastation, one can hope that before long it will be remedied.

A new problem, however, is just beginning to emerge. It has already appeared in India and may soon appear elsewhere. Until recently India was practically self-supporting in food; there was, indeed, an export of wheat and of oil seeds, but also an import of rice. But, thanks to efficient health services organised by devoted British workers, the population has risen rapidly and enormously: in 1931 it was 338 million, but by 1941 it had increased to 389 million. It has now outstripped the present food-producing capacity of the land. India has ceased to export food and has begun to import it. Until recently the growth of world population was mainly met by bringing new land into cultivation; the late Sir Daniel Hall calculated that each new head of population in Great Britain brought into use an additional 2–2½ acres of land, the yields being lower than ours. Much virgin land was still available and easily utilizable. But that kind of land is now all taken up. A great deal of what remains will need large and costly development schemes to make and keep it productive. Unfortunately, too, as in Great Britain, much of the land that has been brought into cultivation has been lost, partly through the same causes as operate here, but largely through another cause from which happily we do not suffer greatly, namely, soil erosion. This has been particularly destructive in the rather dry regions well suited to wheat, and in the wet tropics where lie our largest reserves of potential food-producing land. Prof. C. B. Fawcett has estimated that the area of potentially cultivable land in the world is about 10,000 million acres. (H. L. Shantz's quite independent estimate is higher—17,000 million acres—but includes all land under a 'crop climate', while Fawcett has eliminated mountains and other areas physically unsuitable for cultivation.) About half of this may be regarded as fairly workable. The world population is estimated at something more than 2,000 millions and increases at the rate of 20–25 millions per annum. There appears, therefore, to be about 2½ acres of fairly workable land per head—but constantly shrinking while the population constantly increases. Prasolov estimates that about 10 per cent of the land surface of the world is already cultivated, that is, about 3,600 million acres, 1·8 acres per head.

Britain is for its size the most crowded country in the world, and the most dependent on outside sources of food. We are therefore vitally affected by this fact of decreasing available land and increasing demands upon it. To a large extent the situation is outside our direct control, but under the very able and energetic guidance of Sir John Boyd Orr, the Food and Agriculture Organisation has striven to arouse recognition of the urgency of the problems among all nations.

We can, however, try to do something in Britain itself. It is clearly essential that the remaining soil resources of the nation should be carefully assessed and that the destruction of food-producing land should be halted. Unfortunately, 'planning' has not been conspicuously successful in this direction. Perhaps some better procedure may be evolved, but in the meantime methods of evaluating different soils are being elaborated. This is by no means a simple matter; for soils, climate, and management are so interlocked in food production that it is impossible to express any of them numerically. Soils can, however, be grouped, and two methods have been adopted for doing this. One is by soil analysis. This has hitherto been used chiefly for indicating fertilizer and lime requirements, and for that reason was long subordinated to the advisory section of the county agricultural activities; only recently has it been given an independent status. Large numbers of analyses have been made, but few have been adequately discussed in publications generally available; this defect will, it is hoped, be remedied in time; but meanwhile, methods are continuously under review, and fuller knowledge of the soil factors involved in crop production is being gained. Much good work done in other countries is now available; the most recent summary is contained in the new edition (the fourth) of M. Demolon's well-known treatise "La Dynamique du Sol"; American, Canadian, Australian, Russian and other work has been collated and described by the Commonwealth Bureau of Soil Science.

The other method of evaluating soils is frankly empirical but of great practical value. It is based on their performance in the use to which they are actually put, and it necessitates accurate surveys to discover that use. Agricultural surveys, of course, have long been carried out in Great Britain; the most complete were those made by the first Board of Agriculture in the early years of the nineteenth century, which still remain unequalled. In recent years agricultural officials have collected a great mass of information which has been statistically summarized in the "National Farm Survey of England and Wales" (1946), a most useful publication which provides students, experts and officials with much valuable information, and would have been even better if the parallel survey for Scotland could have been made on the same lines and for the same period, so that the results could have been strictly comparable. It has, however, little descriptive detail, and one could wish that, having collected the material, the Ministry would issue a series of volumes comparable with the old ones. Another survey, more restricted in scope, but more homogeneous in execution, was made of the grass lands of Britain by Sir George Stapledon and his colleagues. The fullest land utilization survey yet made in Britain was carried out under Prof. Dudley Stamp and is discussed below. It is the outcome of much valuable study by British geographers which has not yet received the recognition it deserves, but which has revolutionized geographical science in Britain and has furnished a solid foundation on which a sound scheme of land utilization can be built up. The need is great, and time is pressing.

THE LAND OF BRITAIN AND HOW WE USE IT

The Land of Britain
Its Use and Misuse. By Prof. L. Dudley Stamp. Pp. viii+507. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1948.) 42*s*. net.

BRITAIN has been fortunate in its geographers. As soon as the subject emerged from the purely descriptive to the more scientific stage, the need was realized for detailed studies of the land to find out the uses to which it was being put, and to discover, if possible, why a particular use was adopted. Among the pioneers were H. J. Mackinder who, in his classical work "Britain and the British Seas", discussed the marked differences between the uplands and lowlands of Britain; and H. R. Mill who, in a paper before the Royal Geographical Society, prepared a specimen description of a 1-in. Ordnance Survey map sheet. But it was Patrick Geddes who gave definite form to the idea of setting out the principles on which a survey should be based: starting with a small area and studying it intensively. The idea was taken up with alacrity by teachers of geography throughout Britain: under the wise guidance of H. J. Fleure, they formed themselves into the Geographical Association, which co-ordinated the methods and arranged for periodical discussions and exhibitions of work. In the various colleges and university departments of geography, students were trained in the methods of detailed survey, the pioneers including besides H. J. Fleure, James Fairgrieve, Profs. Eva G. R. Taylor, C. B. Fawcett, S. W. Wooldridge, Dudley Stamp, S. H. Beaver and others. The Le Play Society, founded by Patrick Geddes to carry on the work of the French geographer Le Play, has through its able and energetic director, Miss Margaret Tatton, arranged for its members to make similar studies in various European countries, and these have furnished wider experience and new ideas. Quietly and unobtrusively a large number of surveys were made by the students and staffs of university departments, but owing to absence of means of publication most of them remained only in manuscript. Nor was the work confined to the universities: it penetrated to the schools and it gave a reality and vividness to the teaching of geography that the subject had never had before. Even village schools took the matter up, and some admirable local studies were made.

Those who had seen something of the work and had had an opportunity of studying some of the resulting maps and reports could not help regretting that so much valuable work should lie unappreciated and inaccessible to many to whom it would have been helpful and interesting. The task of collecting and co-ordinating it seemed well-nigh impossible of achievement. Fortunately, Dr. L. Dudley Stamp, on his appointment as Sir Ernest Cassel reader in economic geography at the London School of Economics, realized the great possibilities and was undaunted by the difficulties; he proceeded from 1929 onwards to develop a scheme for a unified survey of Great Britain—acre by acre, every field—to be based on the 6-in. Ordnance Survey Map. The results are published in nine volumes and a series of 1-in. maps, and they furnish a remarkably full record of the land utilization of Britain before the War: they contain much new and valuable information that the busy student would not easily find, and Prof. Stamp has had the happy idea of preparing this summary volume which includes the leading results and gives references to the relevant volumes of the complete survey.

One of the unexpected generalizations that emerges is the steadily increasing part that natural geographical factors play in determining land use, contrary to the general idea that science emancipates mankind from dependence on natural conditions. Interesting examples are given in the chapter on orchards, where the importance of a proper site, especially in relation to late frost, is well brought out. Were it not for its liability to frost, the Wisbech area could, the author states, supply all Britain's requirements in cooking apples; as it is, only a small proportion is grown. It might be thought that practical men would have known this themselves—and, of course, the best of them do—but the surveyors found a surprisingly large number of badly sited orchards, including much of the fruit planted in the eastern counties during the difficult 1930's. Nothing can now be done to improve them.

Market gardening is known to require a light soil and a water-table fairly near the surface; proximity to a steady market is an obvious advantage. The housing developments near London, however, have involved so much drainage that the water-level has fallen and the suitability of the land has therefore lessened. Overhead irrigation has largely met this difficulty, but naturally makes its heaviest demands on water in times of prolonged drought when water supplies are lowest. Supplies of town stable manure and of town refuse used to be important factors in determining the location of market gardens but are so no longer. Nor does the distribution of population much affect the distribution of market gardens, but rather the steadiness of the demand for produce: determined by such factors as freedom from spells of unemployment.

The effect of transport on land utilization is well brought out. The area east of Canterbury was formerly not easily accessible; now, however, motor lorries readily penetrate, and fruit-growing and market gardening have both greatly increased. The author thinks that other regions at present rather inaccessible might similarly be opened up: he mentions some of the outer Hebrides, which have a high average temperature, much sunshine, low rainfall and sandy soils, and might be well used for some types of cultivation.

A final section records the finances of the Survey, and one can only regret that so valuable a piece of work should have had to be so largely paid for by Prof. Stamp himself, a situation that surely calls for recognition. Meanwhile, the book can be cordially commended to all interested in the land of Britain.

E. JOHN RUSSELL

BRITAIN'S SCIENTIFIC WAR EFFORT

Science at War

By J. G. Crowther and R. Whiddington. Pp. vi + 185 + 51 plates. (London: H.M. Stationery Office, 1947.) 2*s*. 6*d*. net.

IN a foreword to this popular account of how science helped the armed forces to win the War, Sir Henry Dale explains that the object of the Scientific Advisory Committee to the Cabinet in securing approval for the preparation of this work was "to make available to the public an authoritative account of some of the more important aspects of the scientific contribution to the war effort, based on official archives, but so written as to be acceptable to the reader without special scientific education". Naturally, the whole field of the scientific war effort cannot be covered in a single volume, and the authors have chosen radar, operational research, the atomic bomb, and science and the sea, because of their wide interest, as typical illustrations. All four are essentially British contributions.

The purely scientific basis of radar had been established before the War; but it was the initial foresight of Dr. H. E. Wimperis and Mr. A. P. Rowe, the inventive genius of Sir Robert Watson-Watt, the timely brilliant production of the cavity magnetron by Prof. J. T. Randall and Dr. H. A. H. Boot, and the close collaboration of scientific workers, military users and industrialists, which first saved us from aerial destruction and then allowed us to attack the enemy with deadly accuracy. The story of radar will perhaps be told in more detail elsewhere, but certainly not so vividly as in "Science at War".

Operational research owed its inception to Mr. A. P. Rowe, then superintendent of the Telecommunications Research Establishment. It is concerned with the study of weapons, tactics and strategy, and the methods which were developed in war-time can be employed, in peace-time, in industry. It is interesting to learn that the first consistent exposition of the principles of operational research was given by Prof. P. M. S. Blackett.

The section on the atomic bomb is the first adequate exposition of the British contribution to the discovery of the atomic bomb and the release of atomic energy. It is good to be reminded that British men of science were the pioneers in nuclear research, and that up to 1941 Britain led the world in this sphere of fundamental research and development. The huge task of the production of the atomic bomb, a remarkable achievement in itself, had to be left to the United States. Mr. Crowther and Prof. Whiddington content themselves and their readers by confining their story to events before the commencement of the American project.

Finally, in "Science and the Sea", we are told how Asdic works, how the magnetic and acoustic mines were defeated, and all about depth-charges and frog-men.

The book is a remarkable half-crown's worth. Not only is the subject-matter presented in an exceedingly interesting fashion, technical and scientific accounts being given in a manner that even those with little technical knowledge can easily follow, but, in addition, the volume is profusely illustrated by numerous line drawings and excellent photographs. If only some of our scientific text-books were as well provided !

S. WEINTROUB

EMPIRES IN TRANSITION

Colonial Policy and Practice

A Comparative Study of Burma and Netherlands India. By J. S. Furnivall. Pp. xiii+568. (Cambridge: At the University Press, 1948.) 36*s*. net.

Soviet Economic Development since 1917

By Maurice Dobb. Pp. vii+474. (London: Routledge and Kegan Paul, Ltd., 1948.) 18*s*. net.

THE history both of the U.S.S.R. and of the colonial territories of European States illustrates the impact of the ideas and activities of the West upon less-advanced peoples, and these two books together provide material for a comparative study which is of particular interest at the present time.

The historian of the future is likely to find less cause for wonder at the changes that have taken place in Britain's imperial position in the last few years than at the fact that that position was ever achieved at all. The century of expansion which seems now to be closing has been, indeed, a remarkable period, and its final effects can no more be estimated yet than can those of the Bolshevik Revolution. Mr. J. S. Furnivall, who has already given us a notable study of Netherlands India, here takes one part of the story, the occupation of Burma, and endeavours to see it, not only as a part of the British achievement, but also, in a wider setting, as an illustration of the clash of cultures. In order to do this he has, in effect, combined several books in one. Of his 550 pages some two hundred are devoted to a survey and critical appreciation of British rule in Burma, and a further sixty to a summary of the material already made available in "Netherlands India". These two descriptive sections are followed by a long and valuable comparative study of British and Dutch policy, in which some comparisons are also drawn with conditions in Africa. Here Mr. Furnivall is, as he admits, "treading on uncertain ground", and the points he makes are largely drawn from the writings of Lord Hailey. Finally, there is what amounts to a political pamphlet, a discussion of current problems, with proposals for their solution. "If one would understand colonial practice", Mr. Furnivall writes, "one must study it both comparatively and historically", and it is "as a contribution to such a study" that the work is intended.

A full survey of colonial government must await the pen of another Toynbee ; but Mr. Furnivall has done much to clear the ground in one part of the world. What he says of Burma elucidates a situation that was already serious before the War and that came to a head under the Japanese occupation. But it does more, for Mr. Furnivall is concerned primarily to show that British rule in Burma, like Dutch rule in Netherlands India, arose as the result of economic and political forces ; that the differences between British and Dutch policy reflect differences in the aims and conditions of existence of the two peoples. The British, with their respect for law and individual activity, tried to establish a system which would leave free play within a system of order ; the Dutch from the first intervened much more directly and sought to mould society, while protecting it as far as possible from the pressure of economic forces by the development of social welfare.

The British method would seem to have failed, for it led, as Mr. Furnivall shows, to "the disintegration of social life through the inadequacy of law to control the working of anti-social economic forces". How far this disintegration had gone in corruption and lawlessness he makes only too clear, and in the preface, written some time after the rest of the book, while approving the recognition of Burmese independence as wise and bold, he feels that "it is impossible to contemplate the future without misgivings". Yet he hopes that Burma's need of help, and a sounder view on our part of our mutual interests, may enable us still to assist in the development of the country; and in his earlier book he has indicated his reasons for believing that the introduction of the "invigorating principles of Western social life" is perhaps "the best justification of European intervention in the East". There has certainly been no lack of ideals, though as Mr. Furnivall shows, in colonial affairs "the lofty aims of policy are continually frustrated in their practical application".

Underlying the whole work, however, is a criticism of colonial rule as such, which finds fullest expression in the following passage : "Contact with the outer world should furnish new sources of inspiration and enrich native social life, art and religion. But the people are not brought into contact with the outer world except in the sphere of economics ; they remain imprisoned in a dying civilization and their social life is impoverished and not enriched." This would seem to be the view of the intellectual leaders of both Burma and Netherlands India. Whether, given the opportunity now presented to them, they can achieve more, remains to be seen. Theirs is the task of reshaping society under the pressure of developments outside their own control.

How the task has been tackled in another society is the theme of Mr. Dobb's book, and the picture of a revolutionary *élite* successfully remoulding Russia and its Eastern territories emerges with the utmost clarity from his pages. The ground has been covered before, notably in Dr. Baykov's "Development of the Soviet Economic System", but Mr. Dobb has given flesh to the bones of Dr. Baykov's study, and produced a work which will have a wide appeal.

The first part surveys the situation before 1917, and the second is a careful study of the development of the Soviet economic system from the Revolution to the end of the Second World War, while the final four chapters contain an analysis of certain aspects of that system in practice. The aim of the book is clearly indicated in its title. Here is a survey of Soviet economic development since 1917: it is not, and is not intended to be, a critical appraisal, nor does it move beyond the range of economic policy, or attempt to estimate, in human terms, the results of the Soviet achievement. Under present conditions such an attempt could scarcely be made, for we are compelled to rely on Soviet statistics and declarations of policy, and cannot, therefore, calculate the significance of the actual achievement for other less advanced peoples of the world. It would be valuable to have more records of the type of Mr. John Scott's "Behind the Urals" (to which Mr. Dobb does not refer), but that we shall have no more of these for some years seems certain. Yet some indication of the conditions under which the Soviet system has worked is given by Mr. Dobb. Thus, in speaking of the difficult early years, he says "A more developed country can afford to brave uncertainty and to learn by trial and error, where a poorer country can bet only on a certainty". Given that this is true, we may ask who decides on the certainty, and how, and who settles the "given canon of social policy" referred to on p. 11, while we recognize that these are also questions that must be asked of colonial administrations.

Underlying the whole study, indeed, are the peculiar conditions—of geography, history, political and social development, resources, and something intangible in the very nature of the people—which have made possible the Soviet experiment (and, in another context, the British Empire). Mr. Dobb feels the force of these conditions, and especially the influence of the last-named, when he writes: "Many have marvelled that men and women could possess the endurance to do such things. . . . No mere heady propaganda or iron hand, but only a rare spirit forged in a people by its history, a boundless faith in their own ability to wring achievement from the future, is capable of inspiring men to endure and to strive as the Russian people have done".

Mr. Dobb is confident that Russia's experience has something of value to offer to the development of other parts of the world, and he makes some stimulating suggestions. But how great, in fact, Russia's direct influence will be we may well wonder, though the force of the Soviet idea is not to be doubted. Taken together, these two books are a valuable commentary on present problems.

It remains to be added that Mr. Dobb has provided useful maps and an index that is worthy of the name. Mr. Furnivall's index and single map are, unfortunately, unworthy both of his book and of the price at which it is published.

Maurice Bruce

A DESCENDANT OF BENJAMIN FRANKLIN

Alexander Dallas Bache, Scientist and Educator, 1806–1867

By Merle M. Odgers. (Pennsylvania Lives.) Pp. vii + 223. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1947.) 15*s*. net.

As the sub-title—"Scientist and Educator"—suggests, this is a biography of one whose influence and work not only enriched science, but also had a profound effect on educational development in the United States. In fact, in the words of Rear Admiral Leo Otis Colbert, the present director of the U.S. Coast and Geodetic Survey, Bache was "one of the great personalities of nineteenth-century America". This man of wide interests was the grandson of a Yorkshireman, Richard Bache, of Settle, and the great-grandson of Benjamin Franklin; it is not surprising that he took such an interest in the development of science and education in Europe.

The book gives an interesting account of Alexander Bache's many-sided activities—his classical education, his training as a cadet at the United States Military Academy, West Point, his European tour during 1836–38, and his activities as head of the Philadelphia Central High School and finally as superintendent of the United States Coast Survey, a post which he held from 1843 for a period of some twenty years. On leaving the Army in 1828, Bache had been appointed professor of natural philosophy and chemistry in the University of Pennsylvania, and in addition to teaching he found time for research and for participating in the activities of learned societies. It was, however, his election as president of Girard College that widened his interests in education and led to the tour through Europe to gather information of methods and institutions. Stephen Girard, merchant and banker, had died in 1831, and in accordance with his will the College was to provide a sound education including a variety of subjects—literary and scientific—and with special reference to "a pure attachment to our republican institutions, and to the sacred rights of conscience". This set a wide horizon to Bache's inquiries abroad, and although he did not ultimately become president of Girard College, his European tour, which included visits to nearly three hundred schools, provided ample material for educational research and forged a valuable link between the Old World and the New.

With regard to his scientific work, the earlier part of Bache's career revealed a great interest in terrestrial magnetism. During the two years that he was abroad, several observations were made by means of portable instruments, and an interesting list of recording stations, varying from Westbourne Green, in London, to the summit of the Faulhorn near Grindelwald, is given on pp. 124–25. Plenty of scope for scientific research was afforded by Bache's appointment as director of the Coast Survey, and after fifteen years work the verdict of the president of the Royal Geographical Society was that though the Americans were last in the field, they had leaped into the very first rank. Apart from survey of the coast, Bache was responsible for detailed study of the Gulf Stream; nor did he neglect geomagnetism. His numerous contributions to learned societies included a paper in the *Monthly Notices of the Royal Astronomical Society* on a new method of observing transits. In the defence of Philadelphia in 1863 Bache played his part in the Civil War, but never recovered from the strain that it entailed.

It is a welcome sign that books of this nature appear from time to time on both sides of the Atlantic. Too frequently the achievements of science have been separated from their background of history and human endeavour. The author is to be congratulated in maintaining a vivid interest in Alexander Bache—the man and his times. There are numerous extracts from original sources and an exhaustive bibliography is appended. H. D. ANTHONY

SCIENTIFIC MANAGEMENT

Time Study and Common Sense

A Critical Study of some Conceptions and Methods with Suggestions for Improvement. By Abraham Cohen. Pp. viii+112. (London: Macdonald and Evans, 1947.) 10*s.* net.

Skill and Management

By G. E. Milward. Pp. x+102. (London: Macdonald and Evans, 1947.) 8*s.* 6*d.* net.

"TIME Study and Common Sense" is a disappointing book. Mr. Cohen explains in his preface that it consists mainly of lectures given to "Time Study engineers" at Royal Ordnance factories. It may be that the book lacks some of the author's personal exposition which may have made his arguments clearer in the lecture room than they are in the book. There is so much misunderstanding and misrepresentation about time study, and so many rather ponderous text-books have been published about it, that a new examination in the light of common sense would have been especially welcome. It is very much to be regretted that Mr. Cohen's work adds nothing but a vague confusion to the subject.

The book is mainly devoted to a rather scathing denunciation of a number of authors of books on time study. Mr. Cohen brings little evidence to support his attacks, and such standard authors as Barnes, Hendry and Carroll scarcely need fear comparison with this unhelpful book.

One or two quotations which are typical illustrate the quality of Mr. Cohen's thought: on p. 5 he states, "a Time Standard is a vague conception", and a little later, a time standard is defined as "some potential output which our workers are supposed to achieve". This is vagueness indeed, but it is wholly of Mr. Cohen's importation.

The main theme of the book is to discredit the method of rating work, and the addition of rest allowances which are almost universally used in time study in Great Britain. Yet this is what Mr. Cohen tells us to do on p. 52 in the chapter on "How to Set a Time Standard": "we should remember that we have to rate the recorded time up, or to rate it down, to a time we consider to be the optimum at which we want and expect our workers to work all the time—on an average". It is to be hoped that time-study men in Royal Ordnance factories found some better basis for their ratings than this.

There is a list of other works on time study at the end of the book, but no subject index.

It is perhaps a pity that the author of the above book did not follow some of the admirable and workmanlike advice given by Mr. Milward in "Skill and Management" upon the way in which the results of an investigation should be presented in writing. This book is a brilliant little work of close and coherent reasoning. Although it is primarily written for the specialist in management, it is safe to say that it could be read with profit and interest by anyone who wishes to keep in touch with modern thought on organisation.

Early in his book, Mr. Milward makes a point of great relevance to current industrial conditions when he analyses the difference between 'effectiveness' and 'efficiency'. The modern tendency towards more and more functional specialization increases the effectiveness with which separate limited ends are pursued, but it is accompanied by a growing difficulty in maintaining managerial efficiency in the broad sense. But, writes Mr. Milward, "effectiveness of performance cannot be expected to survive loss of managerial efficiency for very long".

In addition to its original contribution of some hard, straight thinking, this very well-balanced book quotes freely and appropriately from some of the classical economists and philosophers. J. LEIGH

GAS TURBINES

Modern Gas Turbines

With Special Reference to Stationary, Aircraft, Locomotive and Marine Types and to the Supercharging of Internal Combustion Engines. By Arthur W. Judge. Pp. xi+311+19 plates. (London: Chapman and Hall, Ltd., 1947.) 28*s.* net.

THE published information on gas turbines is both voluminous and widely dispersed, a considerable part of the technical literature of Britain, the United States, Switzerland, Sweden and other countries having been devoted to this subject in recent years. The object of this latest of Mr. Judge's books appears to have been to collect together at least the most important of these articles and papers, and to offer explanations and comments. It is a pity that this worthy object should be marred by several fundamental errors in thermodynamics, such as the statement in Chapter 3 that the efficiency of the Carnot cycle ". . . can also readily be shown to be represented by the following relations:

$$E = 1 - \left(\frac{1}{r}\right)^{\gamma-1}, \quad . \quad . \quad . \qquad (10)$$

where r is the ratio of volume V_0 at 0 to V_1 at 1, i.e., the isothermal compression ratio". It is well known that the isothermal compression ratio has no influence whatsoever on the efficiency of the Carnot cycle, and that r in the equation should be, using the notation of the text, "the ratio of the volume V_2 at 2 to V_1 at 1, i.e., the adiabatic compression ratio".

In the same chapter, the same expression is derived for the efficiency of the Otto cycle and for the constant-pressure cycle. These expressions are correc as they stand, but, no note having been made to the contrary, leave the reader with the impression tha all three cycles amount to very much the same thing which is far from the case.

Far more serious, however, is the confusion which appears to exist in the author's mind on the subjec of entropy. On p. 62 the following statement appears: "The entropy of a given quantity of gas is defined as the ratio of its total heat to its absolute temperature. Thus, Entropy $\varphi = H/T$, where H = total heat reckoned from a given datum level, e.g., absolute zero, and T = absolute temperature". This is a misconception of the first magnitude which must be pointed out, as this book is likely to come into the hands of students whose imagination has been fired by the rapid development of the gas turbine, and whose knowledge of thermodynamics may not be sufficient to detect such errors. There are other errors in the text which make the chapter on thermodynamics unreliable.

However, the book improves when the author confines himself to descriptive work, the chapter on aircraft propulsion being very well done and containing some excellent illustrations.

It seems a pity that more emphasis was not placed on the vast difference between the aircraft gas turbine on one hand, and the land or marine gas turbine on the other. The design of the latter type of machine is a much more difficult proposition than that of the former, both because of the thermodynamic problems involved in converting the kinetic energy of the jet into useful work, and the metallurgical problems involved in finding materials to withstand the working temperatures, not for 500–1,000 hours as in the case of the aircraft turbine, but for ten to twenty years.

The book could serve a useful purpose if some of the errors, particularly in the chapters on thermodynamics, were corrected. One of the most useful features is the bibliography containing eighty-nine references. E. G. STERLAND

CHEMICAL ENGINEERING

Chemical Engineering Fundamentals

By Chalmer G. Kirkbride. (McGraw-Hill Chemical Engineering Series.) Pp. xi+419. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 30*s*.

THE intention of this book is to enable students with little knowledge of chemistry and mathematics and none of physical chemistry to begin the study of chemical engineering, or rather of what are termed "the five technical fundamentals". It opens with a chapter on human relations in chemical engineering; the next deals with "Useful Mathematical Tools". This is followed by "Important Concepts of Physics and Chemistry"—in fifty pages. Of these it might be said that never were so many facts (sometimes not strictly accurate) compressed into so few pages. The effect of reading this part of the book is one of bewilderment and a feeling of agreement with a statement made later that "dogmatism usually irritates most readers". It is doubtful if British students, who are trained to think rather than absorb facts, could take in all that is presented, or if it would be of any value to them if they did. They might well gain the impression, for example, that there are five important aromatic compounds represented by well-drawn formulæ, one of which, styrene, is used to make synthetic rubber. Whether it is a solid, liquid, or gas is apparently immaterial, as are its chemical reactions, other than polymerization.

Apart from this too intensive matter, there are many features in the book which are original and of much value to the discriminating teacher. The chapters on material balance, energy balance, static equilibria, dynamic equilibria and economic balance (though what balances in this case is not clear) are by no means elementary and contain numerous illustrative examples. The first and last chapters, on human relations in chemical engineering and the presentation of technical reports respectively, deal with subjects now recognized as of vital importance and, if not taken too literally, may be read with great advantage not only by teachers but also by those actually engaged in industry. The fifty pages of appendix with fifteen tables and twenty-nine graphs might have been more usefully devoted to the explanation of some of the statements in Chapter 3.

H. E. WATSON

RIVERS—A NATIONAL HERITAGE

Our Rivers

By J. W. Kempster. Pp. xi + 300 + 21 plates. (London, New York and Toronto: Oxford University Press, 1948.) 25*s*. net.

LIFE in Great Britain, while not at first sight greatly influenced by rivers, in actuality is very profoundly affected by them. At one time the rivers were far more than a convenient means of disposal of sewage, and there is an increasing deepening of interest in the restoration of the rivers to something like their pre-industrial condition. Government departments which are greatly interested in these matters include the Ministry of Agriculture and Fisheries (with wide interests in fishing and in the irrigation of farm lands), the Ministry of Health (which watches zealously those rivers which are used for water supplies to the public), the Department of Scientific and Industrial Research (which is interested in water pollution research, and also in the hydraulics), the Ministry of Transport (on account of inland transport, water power, and the dangers of pollution from tarred roads), and many others. Obviously the subject is one that is important to the engineers of towns and cities and to civil engineers in general in relation to land drainage.

The author of this book has dealt comprehensively, if briefly, with all aspects of the matter. As an angler he holds that migratory fish are the best judges of pure water, and he commences by dealing with the life-history of salmon and sea trout. As a natural development he then takes up the subject of obstructions in the rivers, and devotes a chapter to river management, and another one to pollution. There follow several chapters dealing with legislation affecting rivers, and these appear to be of very great value as they cover the activities of the various bodies entrusted by Parliament with the management and control of rivers; and the over-riding Acts of Parliament are summarized. Fifteen appendixes give a mine of varied information in compact form.

The author is an enthusiast on the subject of improvements in the rivers of Britain. He regards them as a national heritage, and seeks to enlist interest and support towards conserving their utility, natural beauty and enchantment. The book is commended to all who are like-minded.

A. T. DOODSON

Canada

A Study of Cool Continental Environments and their Effect on British and French Settlement. By Prof. Griffith Taylor. Pp. xiv+524+8 plates. (London: Methuen and Co., Ltd., 1947.) 25*s.* net.

A STUDY of the geography of Canada was much needed by students, who have little access to any objective consideration of that country. Prof. Griffith Taylor has supplied this want in great measure. The book is based on extensive travels in many parts of Canada and also in Newfoundland, which is included in the volume. Part 1 treats of the position, discovery and general physical features, including climate; part 2 considers the Dominion by natural regions; part 3 is a study of environments as related to man—a careful consideration of occupations and population problems. The whole is illustrated by a wide range of sketch maps and diagrams; many of which show great ingenuity.

Proximity to the North Polar regions has been a certain disadvantage to Canada in the past; but with the advent of aerial navigation may prove an asset, since air traffic is not restricted by ice-bound seas or lands. Great-circle routes are thus becoming of increasing importance. Prof. Taylor admits that he is somewhat of a determinist, that man can accelerate or retard the progress of a country's development, but would be unwise if he attempts to depart widely from the directions indicated by natural conditions. Thus he reaches the conclusion that, keeping to the standards of a rich new country, the population potentiality of Canada is some fifty million, or on general European standards twice that figure. These figures are reached by close reasoning which merits careful attention. The book is a valuable study and indispensable to students.

Surrey

By Eric Parker. (County Books Series.) Pp. viii+256+49 plates. (London: Robert Hale, Ltd., n.d.) 15*s.* net.

THE County Books aim at giving "a true and lively picture of each county and its people set against the background which has made it what it is". The present volume is one of the first of the series and its author is well chosen, being a field naturalist of repute and author of the well-known "Highways and By-ways of Surrey".

It is not a topographical work in the usual sense but contains much of the kind of information not found in guide-books. Without losing sight of his home county, the writer discourses pleasantly on themes which often carry him beyond it. He ranges from ancient camps to women's institutes and from the Pilgrims' Way (which he exposes as a fraud) to Brooklands. In separate chapters he discusses folklore, dialect, the economics of farming in 1850 and the vanished industries. He deals broadly (geologists might say summarily) with soil and structure, and generously with the scanty materials of Surrey archæology. Architecture he leaves to the photographer, and, except for museums and roads, ignores everything urban and suburban.

The greater part of the book is concerned with the author's own study of the life of the countryside. For so accessible a county Surrey has a surprising variety of wild life. Mr. Parker, from personal observation over many years, states that in 1939 it was richer in water birds than at any time in living memory, and he believes there are signs of recovery from the setback due to war-time defence measures. With much first-hand evidence he discusses the habits of nuthatches, crossbills, bullfinches, wrynecks and other rare birds, and, in controversial mood, propounds a theory of the drumming of woodpeckers. The red squirrel, he thinks, has been completely ousted by the grey, but many less familiar mammals—among them water-shrew, badger, polecat, pine marten and hare—still flourish. In similar vein he dilates upon butterflies, moths, dragonflies and the living population of woodland, garden and pond. These chapters contain much of interest for the naturalist and many suggestions to stimulate further inquiry.

The book is well printed and produced, with a good index and many fine photographs of landscape and architectural subjects. To conclude it with a featureless sketch-map dominated by roads and railways is anti-climax. W. E. S.

Introduction to Modern Physics

By F. K. Richtmyer and E. H. Kennard. (International Series in Pure and Applied Physics.) Fourth edition. Pp. xvii+759. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 36*s.*

THERE must be very few students of advanced physics who are unaware of the contents and scope of Richtmyer's important book. The appearance of the fourth edition is indeed most welcome and a matter of hearty congratulation to Dr. Kennard, who has kept the work so well up to date. The additions to the latest edition cover the more important advances of the last five years, and mainly take the form of extensive new sections on the properties of the nucleus, including details of the meson, fission and the transuranic elements, and on cosmic rays. Some basic portions of the chapter on atomic structure and optical spectra have been rewritten, with much advantage.

In the concluding paragraph of the final chapter we find the interesting statement that it will be a dramatic day when mesons are for the first time generated in the laboratory. It appears from recent notes that the announcement of this dramatic discovery was somewhat accidentally delayed, and the reviewer now awaits the announcement that someone with access to a cyclotron is attempting to measure the magnetic moment of a meson by a modification of the Alvarez and Bloch resonance method which was so successful with the neutron. L. F. BATES

Practical Biology for Medical and Intermediate Students

By C. J. Wallis. Second edition. Revised, enlarged and re-set. Pp. ix+396. (London: William Heinemann (Medical Books), Ltd., 1947.) 21*s.* net.

THE second edition of this book has been extensively revised and contains much new material which will, no doubt, add to its usefulness. More than a hundred of the illustrations are new and others replace some which were present in the first edition and which were taken from other text-books. Apart from those taken from other books, the illustrations are very rough sketches which are not improved by crude shading such as one would not welcome in the work of the students for whom the book is intended. They are by no means always accurate, especially in the section on embryology, in which two transverse sections appear to have been drawn upside down, and in which Fig. 197 will do little but mislead. This is not a book which the reviewer would be happy in recommending to students. P. D. F. MURRAY

EFFECT OF PRESENT-DAY WHALING ON THE STOCK OF WHALES

By J. E. HAMILTON
Stanley, Falkland Islands

IN November 1946, the *Norsk Hvalfangst Tidende* (*Norwegian Whaling Gazette*), which is an authoritative journal, published an article on Antarctic pelagic whaling in the season 1945–46. This article contains the ominous statement[1] that although the proportion of mature females taken in the catch shows an increase on the seasons immediately preceding the War, the percentage of mature females which were pregnant shows a marked decline. In blue whales, this percentage was only 20·7 per cent and in fin whales 23·2 per cent. Percentages of pregnant females are also given for five pre-war seasons, the lowest figure appearing in 1934–35 and being 28·7 per cent for blue whales and 33·1 per cent for fin whales.

It is generally believed that the cows become pregnant in alternate years, and therefore one might expect about 50 per cent of the adult females to be in calf; or since the newly mature are, in theory at least, pregnant, the percentage might be somewhat higher. How much higher would depend on the proportion of newly mature cows to those which had already established the breeding rhythm. A drop in this percentage must be the result of three factors: (1) killing of young mature females before they have had time to be impregnated; (2) depletion of the stock of adult females in previous seasons; and (3) depletion of the total stock of adult whales so that a perceptible number of females are not fertilized.

The 1930–31 season was a record in the annals of pelagic Antarctic whaling, and 28,000 blue whales were taken. Succeeding seasons showed an increasing decline in the quality and quantity of the catch, and consequently in 1937 the minimum lengths at which whales were to be killed were fixed by international agreement. These lengths should be compared with the lengths at which whales become sexually mature; Mackintosh and Wheeler[2] published the following figures in 1929, and Mackintosh[3] produced revised lengths in 1942.

			1929	1942	
Blue	whales,	male	74 ft. 2 in.	74 ft. 2 in.	(no change)
,,	,,	female	77 ft. 9 in.	77 ft. 1 in.	(reduced 8 in.)
Fin	,,	male	63 ft. 8 in.	63 ft. 0 in.	(,, 8 in.)
,,	,,	female	65 ft. 7 in.	65 ft. 3 in.	(,, 4 in.)

Matthews[4] gives the following lengths for the humpback whale:

Males	39 ft. 4 in.
Females	41 ft. 0 in.

Now the figures decided upon by international agreement as the minimum for permissible killing are:

Blue whales	70 ft.
Fin whales	55 ft.
Humpback whales	35 ft.

In every case the length is well below that at which the animal attains sexual maturity, and consequently the young cows will not have had time to reproduce.

Since the period of gestation is stated to be just over ten months for blue whales and eleven and a half months for fin whales, and the addition of the suckling period of six or seven months gives a total of about eighteen months from conception before the calf can fend for itself[2], it is obvious that the legal size limit has been fixed too low to be effective in preserving the stock. In fact, the habitual killing of immature whales of both sexes is a particularly and obviously efficient way of exterminating a species, although the effect may not be noticeable until a fair proportion of adults are dead, either naturally or by modern whaling methods.

The season 1940–41 was the last of the 'pre-war' series and the catch was comparatively small; eleven factory ships taking 12,744 blue and fin whales. A number of ships were captured or destroyed, but some of the records, at least, have survived; one factory ship went to the Antarctic whaling grounds in each of the seasons 1943–44 (837 whales) and 1944–45 (1,595 whales). However, speaking generally, there was a 'rest' from the depletion of the stock for four and a half years during 1941–45. In this period, mature females could each have produced two calves and could have become pregnant again by 1945–46, when whaling was resumed on a large scale. Now, in spite of this 'rest', the percentage of blue whales in the 1945–46 catch was only 30·7 per cent, "the lowest hitherto met in pelagic whaling in the Antarctic"[1].

The practice of the whalers is to try to catch the largest whales—the gunner who does this gains in reputation; but any whale is better than none, since the factory ships have to be filled with oil. Since the average length of the whales killed is decreasing, it must be concluded that either the larger whales are becoming more difficult to catch or that they have been pretty well killed off. The former assumption cannot stand, for against powerful modern catchers the bolting whale stands no chance. It must take frequent breaths while travelling at speed, remaining practically at the surface all the time, and so can be easily followed and run down. With regard to the latter assumption, the remarks made to me after the last Antarctic season by a very experienced whaler are pertinent. He told me that blue whales were not what they used to be, and that the enormous animals of past years were either extremely scarce or non-existent. I can remember one day in South Shetland when five or six whales were brought in, one male of 89 ft., the rest being females all 90 ft. or more. The inevitable conclusion is that the larger animals have been killed off, and that the survivors do not live long enough to attain the great size of former years. Absence or rarity of the largest examples of a wild species which is habitually hunted is a sign of a diminishing stock[5].

In making returns in the whaling industry it is customary to express the catch in 'blue whale units'. This is a deceptive practice, and does not give a true summary of the whales taken. At no time in the history of Antarctic whaling has there been a pure blue whale catch. Two principal species, the blue and fin whales, are hunted and contribute to the catch; and at one time a third species, the humpback, was also caught, but now seems to be thoroughly reduced in numbers. In the 'blue whale unit' system, the following equivalents are used:

1 blue whale = 2 fin whales = 2½ humpbacks = 6 sei whales.

These are valid equivalents; but the important point is this—the agreed figure for the last two whaling seasons of 16,000 'blue whale units' for the contracting parties may well mean that a full catch involves the killing of many more than 16,000 animals. For example, in 1945–46 the Antarctic catch was returned[6] as 8,304·8 'blue whale units', but was, in fact, made up of 13,381 whales (3,604 blue, 9,184 fin, 238 humpback and 81 sei whales, as well as 239 sperm whales and 35 "sperm and others"). This last might include some bottlenose or *Berardius*. The catch for 1946–47 has been returned[7] as 15,230·7 'blue whale units'. This represents 8,870 blue, 12,857 fin and 2 sei whales, a total of 21,729 whales[8].

There is obviously a serious danger of losing sight of the reality of the position by continued contemplation of the 'blue whale unit' value of a catch, since the number of animals killed will always be greater than the number of units allowed. An industry of this sort cannot be regulated by reference to abstractions, when it depends entirely upon a stock of wild animals, over the lives and breeding habits of which there is no control.

In the presence of vast and unestimated numbers of animals which it is desired to exploit commercially, nothing is easier than to persuade oneself that the stock is so great that it is impossible to injure it, still less to destroy it. But it is my opinion that the stocks of blue whales are showing clear signs of reduction: (1) in the rarity or absence of the huge animals of earlier seasons; (2) in the reduced proportion in the total catch of this species; and (3) in the reduced percentage of mature females which were pregnant. It is also certain that a parallel reduction of the stock of fin whales is now in progress.

The position with regard to sperm whales is somewhat different. These animals are polygamous, and there are therefore spare bulls which can very well be utilized. The sperm whales occurring outside the warm waters of the breeding grounds are almost invariably large males, which have not been able to keep their place in the herds. There is, however, no information as to the size of this stock of spare bulls, or whether they are resident in the Antarctic. Hence, the present increased killing may simply be using up the accumulation of years, either of a resident male stock, or of an annually visitant herd. The appropriate literature is not available here; but I have the clearest recollection that in the days of the old sperm whalers, certain solitary bulls were known to haunt particular areas of the sea, and continued to do so for years. Such whales, like the authentic 'Moby Dick' and 'Paita Tom', attacked boats at sight.

Finally, it may not be out of place to recall to memory the fate of the North American bison and the passenger pigeon. The former was brought to the verge of extinction and the latter completely exterminated by man for commercial purposes, in spite of the almost incredible numbers in which they both existed a little more than a century ago.

THE ENZYME-SUBSTRATE COMPOUNDS OF CATALASE AND PEROXIDES

By BRITTON CHANCE*

Biochemical Department, Medical Nobel Institute,
Stockholm, and Molteno Institute, University of
Cambridge

CATALASE is a hæmatin enzyme found in relatively large concentrations in erythrocytes, liver, kidney, etc. Its extremely efficient catalysis of the destruction of hydrogen peroxide and its ability to catalyse the oxidation of alcohols by hydrogen peroxide have been recognized for some time, but very little direct evidence for the mechanisms of these reactions in terms of the theory of enzyme-substrate compounds has hitherto been obtained.

Using a micro form of the method of Hartridge and Roughton[1] and Millikan[2] for rapid spectrophotometric studies[3] of the reaction kinetics and equilibria of the unstable compounds of catalase with hydrogen peroxide and methyl or ethyl hydrogen peroxide, the catalytically active enzyme-substrate compounds of catalase with these substances have been discovered. In addition, corresponding inactive forms of the compounds of catalase with hydrogen peroxide and methyl hydrogen peroxide have been revealed. The catalase – ethyl hydrogen peroxide complex which had previously been studied by Stern[4] is shown to be one of these inactive enzyme-substrate compounds. The three active enzyme-substrate complexes share a common property of oxidizing substances such as alcohols, and in this case catalase functions as a peroxidase. But the active catalase – hydrogen peroxide complex has the unique property of acting 'catalatically', that is, of decomposing hydrogen peroxide directly into water and oxygen. These studies have shed some light on the mechanisms of these reactions.

Spectra of the Primary and Secondary Compounds

The colour of the three active or primary (I) enzyme-substrate compounds of catalase is pale green, and they have an absorption band at about 670 mμ. The Soret band is decreased in intensity and is slightly shifted towards the visible region of the spectrum, giving an isobestic point at about 435 mμ[5]. At 405 mμ the decrease of extinction coefficient per mole of hæmatin iron bound by peroxide is the same for the three primary complexes. Under suitable conditions the green compounds change into inactive or secondary (II) red compounds having two bands, at 536 and 572 mμ, approximately in the positions found by Stern[4] for catalase – ethyl hydrogen peroxide. The green-red shift of the hydrogen peroxide compounds superficially resembles that found by Theorell[6] for horse-radish peroxidase and hydrogen peroxide. By analogy with his views, the green primary compounds are ferric iron peroxide complexes with ionic bonds, and the red secondary compounds are ferric iron peroxides with covalent bonds.

* John Simon Guggenheim Memorial Fellow.

Molecular Composition of Catalase – Hydrogen Peroxide

In the primary compound of erythrocyte catalase and hydrogen peroxide three out of four hæmatin-iron groups of catalase can still react with cyanide ion or alkyl hydrogen peroxide. Thus the maximum concentration of catalase – hydrogen peroxide found under any condition corresponds to only one of the total number of hæmatins present in the catalase molecule. But the alkyl hydrogen peroxides combine with all four hæmatins, as is shown by the inability of their catalase compounds to combine with cyanide. This difference in composition of the primary hydrogen peroxide and alkyl hydrogen peroxide compounds causes a four-fold difference in the decrease of the intensity of the Soret band of catalase when these compounds are formed.

While a catalase in which all four hæmatin groups are combined with alkyl hydrogen peroxide is relatively stable except in the presence of alcohols, the attachment of more than one molecule of hydrogen peroxide to catalase results in an as yet undetected complex which rapidly decomposes. It is this 'catalatic' activity which limits the saturation value of the primary catalase – hydrogen peroxide complex to one hydrogen peroxide molecule per catalase molecule. This complex is the enzyme-substrate compound concerned in the decomposition of hydrogen peroxide, but it does not exhibit the properties of a Michaelis intermediate compound because the hydrogen peroxide not only unites with catalase to form the enzyme-substrate complex but also reacts again with this complex to cause the decomposition of hydrogen peroxide. Therefore, no Michaelis saturation effect is to be expected, and the velocity of destruction of hydrogen peroxide by strong catalase solutions is directly proportional to the hydrogen peroxide concentration, at least up to 0·3 *M*[7]. The previous evidence for a Michaelis constant of 0·025 *M* appears to be an artefact due to the inactivation of catalase.

Kinetics of Formation and Decomposition and the Enzyme-substrate Affinity

Of the three primary complexes, that with hydrogen peroxide forms the most rapidly ($k_1 \sim 3 \times 10^7$ M^{-1} sec.$^{-1}$ (see ref. 5), that is, in a 1 *M* hydrogen peroxide solution the complex would be half-formed in about $\frac{2\cdot3 \log 2}{3 \times 10^7}$ sec.) and the larger the peroxide molecule, the slower the reaction ($\sim 1 \times 10^6$ and $\sim 1 \times 10^4$ $M.^{-1}$ sec.$^{-1}$ for methyl and ethyl hydrogen peroxide respectively). This decrease is much greater than could be expected solely upon the basis of diffusion velocities and must be attributed mainly to a steric effect, due possibly to restricted accessibility of catalase hæmatin to these substances. In these three reactions, the kinetics of the formation of the primary complexes clearly represent the direct combination of catalase with peroxide without the formation of any detectable intermediates. The primary complexes are not stable ; they decompose spontaneously into free catalase with a velocity constant of about 0·02 sec.$^{-1}$ (the half-time for the reaction is $\frac{2\cdot3 \log 2}{0\cdot02}$ sec.) even in the complete absence of alcohols.

Catalase shows the highest affinity for hydrogen peroxide 10^{-9} *M* (that is, a steady-state concentration of about 10^{-9} *M* hydrogen peroxide is required for half-saturation of the primary catalase – hydrogen peroxide complex). This high affinity is not obtained when hydrogen peroxide 'from the bottle' is added to catalase, for then the value is $1\cdot6 \times 10^{-6}$ *M* (at a $3\cdot4 \times 10^{-6}$ *M* catalase concentration[5]), due to the partial destruction of hydrogen peroxide during formation of the primary catalase – hydrogen peroxide complex. Catalase has an affinity equivalent to about 10^{-8} *M* for methyl hydrogen peroxide and about 10^{-6} *M* for ethyl hydrogen peroxide. These values are all increased in the presence of substances such as alcohols which cause the decomposition of these complexes.

The secondary compounds of catalase and these peroxides are formed from the primary compounds comparatively slowly, are much more stable than the primary compounds, and do not appear to react directly with alcohols. They are thus inhibitors of the catalytic activity of the primary complexes.

Reactions of the Primary Complexes with Alcohols, etc.

Keilin and Hartree[9,10] have demonstrated that catalase and hydrogen peroxide or ethyl hydrogen peroxide can oxidize alcohols. These studies show that the primary catalase peroxide complexes are the active agent in these oxidations and are true Michaelis compounds since they fulfil the tests applied to the peroxidase – hydrogen peroxide complex[8]. The reaction-velocity constants for the reaction of the primary compounds with alcohols, etc. (calculated from the formulæ developed for peroxidase[8]), are very nearly independent of whether hydrogen peroxide or methyl or ethyl hydrogen peroxide is bound to catalase, and have values which decrease with the increasing size of the alcohol molecule, as is the case with the increasing size of the peroxide molecule. The velocity constant with ethanol or methanol is $k_4 \sim 1000$ M^{-1} sec.$^{-1}$ (the turnover of the primary compounds in the presence of 0·001 *M* ethanol is $1000 \times 0\cdot001$ times per sec.). The reactions of these three catalase peroxides with alcohols are not inhibited by carbon monoxide.

Direct spectroscopic measurements of the primary compound of catalase and hydrogen peroxide have been obtained in the presence of notatin, glucose, and oxygen. The absolute spectrum of the compound has been obtained with the Beckman spectrophotometer in the region 370–460 mμ and completely confirms the spectrum obtained using 'bottle' hydrogen peroxide and the rapid flow technique[5].

The direct spectroscopic studies of the turnover number of the catalase peroxides in presence of different alcohols agree with Keilin and Hartree's data obtained in coupled oxidations[10]. In such coupled oxidations the saturation of the catalase – hydrogen peroxide complex is found to be small in spite of the extremely high affinity of catalase for hydrogen peroxide. Therefore, the steady state hydrogen peroxide concentration during efficient coupled oxidations is only about 10^{-9} *M*. Only under these conditions is all the hydrogen peroxide utilized for alcohol oxidation and no molecular oxygen is evolved.

Two other biologically important substances have been found to react with catalase peroxides just as rapidly as do ethanol or methanol. These are formaldehyde (probably as methylene glycol) and formate. By a combination of the chromotrophic acid method[11] for formaldehyde production or disappearance and an acidimetric method using brom-cresol purple for formic acid production and disappearance, the conversion of methanol to formaldehyde and formic acid, and the destruction of the latter, have been determined using ethyl hydrogen peroxide as the substrate. Similarly, carbon dioxide production from formate can be demonstrated in 'coupled oxidations' in which hydrogen peroxide is the substrate (Keilin and Hartree, personal communication).

The reaction of catalase – ethyl hydrogen peroxide with ethanol apparently gives acetaldehyde from ethanol and ethanol from ethyl hydrogen peroxide; the supply of ethanol is not at all depleted during the oxidation, and a small initial ethanol concentration may cause the reduction of a large amount of ethyl hydrogen peroxide. The destruction of strong ethyl hydrogen peroxide solutions by catalase studied by Stern[4], in which catalase is almost completely converted into the secondary compound, can be explained on the basis of a small percentage of the primary compound in equilibrium with the secondary compound. This primary compound reacts rapidly with ethanol present in ethyl hydrogen peroxide, and a small initial ethanol concentration will therefore cause the reduction of all the ethyl hydrogen peroxide. Thus the normal reactions of the primary compound were masked by the presence of Stern's inactive red complex.

The fact that catalase has a high affinity for ethyl hydrogen peroxide appears to contradict the results obtained by Stern[13], who failed to find appreciable inhibition of the destruction of hydrogen peroxide by catalase until about 0·1 *M* ethyl hydrogen peroxide solutions were used. However, these spectroscopic measurements show the 'stripping off' of alkyl hydrogen peroxide groups bound to catalase hæmatin upon the addition of hydrogen peroxide, with the result that only the catalase – hydrogen peroxide complex remains. In experiments in which hydrogen peroxide is continuously generated by notatin, glucose and oxygen, the rapid turnover of a large amount of catalase-bound alkyl hydrogen peroxide is observed spectroscopically. Thus hydrogen peroxide can take the place of an alcohol and can react with catalase alkyl peroxides. It does so with about the same velocity as it reacts directly with catalase. Therefore hydrogen peroxide has a reactivity of about 30,000 times $\left(\frac{3 \times 10^7}{10^3}\right)$ that of ethanol.

By a comparison of the activity of catalase-peroxides towards methanol, methylene glycol, and formic acid (all three are equally active) and ethanol, acetaldehyde, and acetic acid (the latter two are nearly inactive), it is concluded that both a hydroxyl group and a hydrogen atom attached to the one carbon atom are required of a suitable oxygen acceptor. The acceptor action of hydrogen peroxide constitutes an exception to this rule. Since the reaction velocity of both substrate and acceptor decreases with increasing size of the acceptor or substrate molecule, the acceptor molecule may have to pass through the same 'hole' as the substrate and may momentarily become attached to or near the catalase iron peroxide complex.

Secondary Compound of Catalase and Hydrogen Peroxide

When catalase is continuously supplied with hydrogen peroxide by means of notatin, glucose, and oxygen, the slow conversion of the primary to the secondary complex ensues, and the two-banded spectrum (536 and 572 μ) may be seen in the hand spectroscope. Since these bands are close to those reported by Lemberg and Foulkes[14] for a compound of catalase and ascorbic acid, and since hydrogen peroxide formed by autoxidation of ascorbic acid has already been shown to give rise to the primary complex[5], there appears to be little evidence for the existence of this catalase – ascorbic acid complex.

The secondary complex has not yet been observed spectroscopically by adding 'bottle' hydrogen peroxide to catalase owing to the decomposition of the hydrogen peroxide in a fraction of a second. Under the conditions used in the determination of Kat *F*, catalase is in contact with 'bottle' hydrogen peroxide for ten minutes or more. The observed slow decrease of activity during this time has been proved to be due mainly to the formation of the secondary complex, since after the secondary complex has been formed by notatin, glucose, and oxygen, the diluted solution has only half the Kat *F* of the untreated solution. Furthermore, at *p*H 3·5 the rate of decrease of activity[7] and the rate of formation of the secondary complex in the presence of notatin, glucose, and oxygen are both accelerated. The extent of inactivation of catalase depends upon the number of catalase hæmatins converted to the secondary complex, and this varies with the experimental conditions.

This explanation of the inactivation of catalase by hydrogen peroxide justifies the new method for the determination of catalase activity, in which strong enzyme solutions are used so that the reaction is complete in a few minutes[7]. In this procedure there is insufficient time for the formation of the secondary complex and a nearly constant activity is therefore observed.

Reaction Mechanisms

The nature of the reaction velocity constants obtained in these experiments suggests the following overall equations. The symbol "Cat" represents the four ferric-iron atoms of catalase hæmatin to which the peroxides become attached. The hydroxyl group found by Agner and Theorell[15] is considered to be replaced by the peroxide group. The equations are written in terms of methyl hydrogen peroxide and ethanol for simplicity, but similar reactions have been measured with ethyl hydrogen peroxide as substrate, and with several lower alcohols, formaldehyde, and formate in place of ethanol.

$$\begin{aligned}\mathrm{Cat(OH)_4} + \mathrm{4CH_3OOH} &\xrightarrow{1 \times 10^6\ M^{-1}\ \mathrm{sec.}^{-1}} \mathrm{4H_2O} + \\ \mathrm{Cat(-OOCH_3)_4} - \mathrm{I}^* &\xleftrightarrow{<0{\cdot}01\ \mathrm{sec.}^{-1}} \mathrm{Cat(-OOCH_3)_4} - \mathrm{II}. \quad (1)\end{aligned}$$

$$\begin{aligned}\mathrm{Cat(-OOCH_3)_4} - \mathrm{I} + \mathrm{4C_2H_5OH} &\xrightarrow{1100\ M^{-1}\ \mathrm{sec.}^{-1}} \\ \mathrm{Cat(OH)_4} + \mathrm{4CH_3OH} &+ \mathrm{4CH_3CHO}. \quad (2)\end{aligned}$$

Thus the oxidation of alcohols by the primary catalase alkyl hydrogen peroxide complexes follows the simple theory of Michaelis and Menten, where $\mathrm{Cat(-OOCH_3)_4-I}$ is the Michaelis compound. The conversion of this primary compound into the secondary compound is negligible when the alcohol concentration is large and the peroxide concentration is small.

In Stern's experiments[4] the ethyl hydrogen peroxide concentration exceeded the ethanol concentration, and catalase was mainly in the form of the secondary complex which he mistook for the active enzyme-substrate complex.

The oxidation of alcohols by the primary catalase hydrogen peroxide complex may also be regarded as following the Michaelis theory if proper allowance is made for the reactions of this complex with hydrogen peroxide (see equation 5) and for the fact that only one of the four catalase hæmatins is bound to hydrogen peroxide in this complex.

$$\mathrm{Cat(OH)_4 + H_2O_2} \xrightarrow[<0{\cdot}02\ \mathrm{sec.}^{-1}]{\sim 3 \times 10^7\ M^{-1}\ \mathrm{sec.}^{-1}} \mathrm{H_2O} +$$
$$\mathrm{Cat(OH)_3(-OOH) - I^*} \longleftrightarrow \mathrm{Cat(OH)_3(OOH) - II.} \qquad (3)$$

$$\mathrm{Cat(OH)_3(OOH) - I + C_2H_5OH} \xrightarrow{1000\ M^{-1}\ \mathrm{sec.}^{-1}}$$
$$\mathrm{Cat(OH)_4 + CH_3CHO + H_2O.} \qquad (4)$$

The overall mechanism for the destruction of hydrogen peroxide by catalase is represented:

$$\mathrm{Cat(OH)_4 + H_2O_2} \xrightarrow[<0{\cdot}02\ \mathrm{sec.}^{-1*}]{\sim 3 \times 10^7\ M^{-1}\ \mathrm{sec.}^{-1}}$$
$$\mathrm{Cat(OH)_3(-OOH) - I^*} \longleftrightarrow \mathrm{Cat(OH)_3(OOH) - II.} \qquad (3)$$

$$\mathrm{Cat(OH)_3(OOH) - I + H_2O_2} \xrightarrow{\sim 3{\cdot}5 \times 10^7\ M^{-1}\ \mathrm{sec.}^{-1}}$$
$$\mathrm{Cat(OH)_4 + H_2O + O_2.} \qquad (5)$$

Although similar equations were previously proposed (for a summary see Sumner[16]), it is only now that they find experimental support. First, each step in equation 3 has been observed spectroscopically, and kinetic data have been obtained. Secondly, the reactions of $\mathrm{Cat(OH)_3(-OOH)-I}$ with alcohols according to equation 4 have been followed spectroscopically, as has the following reaction of catalase-bound alkyl hydrogen peroxide with hydrogen peroxide:

$$\mathrm{Cat(-OOCH_3)_4 + 4H_2O_2} \xrightarrow{3 \times 10^7\ M^{-1}\ \mathrm{sec.}^{-1}}$$
$$\mathrm{Cat(OH)_4 + 4CH_3OH + 4O_2.} \qquad (6)$$

It is therefore concluded that the second step of 'catalatic' activity is a second-order reaction of $\mathrm{Cat(OH)_3(-OOH)-I}$ with a second molecule of hydrogen peroxide according to equation 5. Thirdly, equations 3 and 5 indicate that, prior to the formation of appreciable amounts of the secondary complex, the overall velocity of decomposition of hydrogen peroxide will increase linearly with initial hydrogen peroxide concentration over a wide range. This is true at least up to 0·3 M, since the Michaelis constant of 0·025 M is an artefact[7]. In addition, the rapid and slow phases of catalase activity found by George[17] probably represent catalase activity in the absence and in the presence of the secondary complex.

In efficient coupled oxidations, the steady-state concentration of hydrogen peroxide is so low that the reaction velocity according to equation 5 is negligible compared with that according to equation 4. Therefore no molecular oxygen is evolved and hydrogen peroxide is utilized quantitatively in the oxidation of alcohol to aldehyde.

The reactions 1 and 2, 3 and 4, and 1 and 6, representing the 'peroxidatic' activities of catalase, can be analysed according to the Michaelis theory; but equations 3 and 5, representing the 'catalatic' destruction of hydrogen peroxide, cannot, since consecutive reactions of hydrogen peroxide with catalase and catalase–hydrogen peroxide are involved, and the saturation value of the catalase–hydrogen peroxide complex depends upon the relative velocities of these reactions. The formation of a catalase hydrogen peroxide complex containing one hydrogen peroxide molecule per four catalase hæmatins can be explained in two ways:

A purely 'kinetic' explanation is that the ratio of the velocity constant for the hydrogen peroxide reaction of equation 5 to that of equation 3 is 3 : 1; hence the maximum concentration of the catalase–hydrogen peroxide complex is a quarter the enzyme concentration. In this mechanism for equation 5, the hydrogen peroxide molecule may collide directly with the peroxide group attached to hæmatin or may collide with one of the three free catalase hæmatins to give, in either case, oxygen, water and free catalase. In the latter case, a catalase with only one hæmatin group would be 'catalatically' inactive (for a more detailed discussion see Theorell[18]). A second explanation assumes 'special properties' of the catalase–hydrogen peroxide complex. The existence of this complex is necessary for the decomposition of hydrogen peroxide into free oxygen and water or into radicals at the free catalase hæmatins, but the complex itself is not decomposed by these reactions. The complex may, however, decompose spontaneously or on reaction with alcohols, etc. In this case also a one-hæmatin catalase would be 'catalatically' inactive. These two mechanisms give very nearly identical mathematical solutions over the ranges of experimental conditions that can now be investigated with accuracy, and therefore a final conclusion on the exact mechanism for 'catalatic' activity is not yet possible.

A comparison of equations 2, 4 and 6 with equation 5 indicates that there is no fundamental difference between the 'peroxidatic' and 'catalatic' reactions; 'catalatic' activity appears to be the special case of peroxidatic activity when the substrate and acceptor are identical.

Complete papers on these experiments will be published elsewhere.

I wish to acknowledge my gratitude to those who have taken an active interest in the progress of this research and who have made many useful criticisms and suggestions: Profs. H. Theorell, L. Pauling, D. Keilin and F. J. W. Roughton, and Dr. E. F. Hartree. I am indebted to Dr. R. K. Bonnichsen for supplying the bulk of the catalase preparations used in these experiments.

THE TELECOMMUNICATIONS RESEARCH ESTABLISHMENT, MALVERN

AN exhibition of the work carried out at the Telecommunications Research Establishment of the Ministry of Supply was held at Great Malvern during May 25–27. This was the first occasion on which this well-known establishment has been open to the public. The Telecommunications Research Establishment, or T.R.E. as it is generally called, became famous during the war years on account of the pioneering research on radar carried out there. It developed from the small research group at Bawdsey originally under Sir Robert Watson-Watt to become one of the largest Government research establishments and attracted many of the leading scientific workers in Britain.

During the War, T.R.E. was responsible for research and development of most of the radar equipment for the Royal Air Force. The story of this work is now very well known. At the close of hostilities many of the leading scientific workers at T.R.E., as was indeed expected, returned to academic life. A considerable number of war-time recruits, however, stayed on in the Government Scientific Service and have carried on the tradition of T.R.E. After the War the activities of the Establishment were broadened in scope and a considerable part of the effort on military problems was turned to civil problems and to fundamental research.

The Establishment is now divided into three Departments—Physics, Radar and Engineering. The Physics Department is mainly concerned with fundamental research on the properties of extremely short radio waves, on infra-red radiation and on various fundamental problems in electronics. It includes a theoretical physics group. Some research on supersonics is also being carried out and the application of radar techniques to various problems in meteorology is being studied. A considerable part of the work of the Physics Department is supported and financed by the Department of Scientific and Industrial Research. The Radar Department is responsible for research and development of radar equipments for the Royal Air Force, the Naval Air Arm and the Ministry of Civil Aviation. Examples of projects on which research is taking place are the location by radar of bombing targets, the location and attack of enemy aircraft, radio navigational aids and the use of radar for the control of air traffic. The Engineering Department is responsible for the design and construction of apparatus to the requirements of the scientific staff and for investigating new materials, finishes and component techniques to meet the wide variations of temperature and humidity encountered at high altitudes and in various parts of the world. It includes the Engineering Unit, which is one of the largest and best equipped workshops in Britain.

The Ministry of Supply School of Electronics is situated within T.R.E. Technical instruction is provided in the School for craft and engineering apprentices. Radar courses are arranged for all classes of new entrants, and advanced refresher courses for internal staff. A department of the Atomic Energy Research Establishment is also at present situated at T.R.E. It is concerned with the development of high-energy particle accelerators for nuclear physics and medical research work, and with electronic instrumentation for measuring all forms of radiation in the field of nuclear physics.

The exhibition was opened on May 25 by the Right Hon. G. R. Strauss, Minister of Supply. On that day leading representatives of the Fighting Services, the Civil Service, universities and industry, together with representatives of the Press, were shown a selection of the work of the Establishment. On May 26, about 1,400, representing other Government establishments, industry, and the universities and technical colleges, attended the exhibition. On May 27, senior science scholars from local schools and members of the public from Malvern and nearby towns attended the exhibition. This was made an occasion for the formal opening of the Ministry of Supply School of Electronics by Mr. J. Freeman, M.P., Parliamentary Secretary to the Ministry of Supply.

It was clearly possible to show only a selection of the work of T.R.E. This selection was representative of that carried out in all departments, and items were chosen which were free from any security restrictions. A few of the more interesting exhibits are described below.

Application of Radar to Meteorology

A number of exhibits illustrated the application of radar techniques to meteorology. Photographs of rain clouds and of the radar echoes obtained from them were shown. A light-weight microwave radar equipment, for installation in large civil aircraft, was demonstrated. This equipment is to enable aircraft to avoid dangerous clouds, particularly those of the cumulo-nimbus type. Fortunately this type of cloud gives an excellent radar echo at a wave-length of 3 cm. at which the equipment operates. An interesting problem in the study of rain is the determination of the size of raindrops, particularly immediately below precipitating clouds. A method of making this kind of measurement by use of a specially designed microphone in an aircraft was exhibited. An interesting application of pulsed light to the measurement of the height of the cloud base was also shown. Another application of radar techniques is the radar sonde. Radar is used to locate the position of the sonde carried on a balloon. Thus observations of wind speed can be made from a single station. Meteorological information as determined by the instruments carried in the sonde is transmitted to the ground by the train of radar pulses.

New Developments in Microwave Technique

A number of exhibits illustrated the development of microwave technique for wave-lengths near 3–10 cm. These included demonstrations showing the improvement of receiver performance and the development of very high power transmitters, both aimed at increasing the range of detection by radar equipment. The development of techniques to enable even shorter wave-lengths to be used was illustrated. One exhibit, for example, showed the method of construction of valves for wave-lengths of the order of 8 millimetres and of the associated microwave components.

D.C. Amplifier using Magnetic Modulator

The amplification of small direct currents is much more difficult than that of small alternating currents, and the technique generally adopted is to turn the direct current into alternating current before amplification. A new type of amplifier which uses a magnetic modulator to effect this conversion was exhibited. The apparatus is particularly suitable for amplification of small signals from low-impedance sources such as thermocouples.

Electronic Digital Computing Techniques

An electronic 'memory' for a computing system was demonstrated. This is based on the storage of an electrostatic charge distribution produced on the fluorescent screen of a cathode ray tube by a bombarding beam of electrons. Many binary numbers of 32 digits can be simultaneously remembered by this system, which has been developed in association with Prof. F. C. Williams of the University of Manchester. A binary number arithmetical unit was also shown which will add together two 32 digit binary numbers in a time of the order of 350 microseconds.

Infra-red Research

A number of exhibits illustrating the use of infrared radiation for the detection of temperature differences were shown. For radiations in the range of 1–3 microns the very rapid response of the lead sulphide type of cell makes it useful for the detection of temperature changes which are very short-lived. One exhibit illustrated its use for the detection of hot spots caused by friction. These may last only a small fraction of a millisecond but are clearly shown by the lead sulphide detector. The use of an electronic A.C. amplifier operating at a frequency of 5 cycles per second in conjunction with a thermocouple of special design was shown as an example of an extremely sensitive detector of radiation arising from bodies having only a small difference in temperature from their surroundings. The amplifier is thought to be the best of its type designed so far and is capable of showing the Johnson noise from a 1-ohm resistance in a band-width of 1 cycle per second.

Automatic Recording Spectrophotometer

An automatic recording spectrophotometer which has been designed for the Medical Research Council was exhibited. This instrument enables an ultraviolet absorption spectrum of a substance in liquid solution to be obtained as a trace on photographic paper. The wave-length scale and absorption are simultaneously recorded on the photographic paper so that on development complete information is obtained without further calibration. This enables specimens to be examined with extreme ease and rapidity. The instrument provides an excellent example of the use of electronic servo mechanisms.

Automatic Following Telescope

A working model of an astronomical telescope locked by electronic means to a star at which it is pointed was shown. The telescope contains a device capable of determining the position of a star in its field of view, and any deviation of the star from the centre of the optical system produces correcting signals which drive the telescope to keep the star centrally aligned.

Air Traffic Control

By means of radar equipments sited at Malvern and near London airport a display showing the position of air traffic in the southern half of England was shown. The exhibit illustrated the control of aircraft arriving at a busy airport using radar information.

Airborne Radar

A number of exhibits showed the latest improvements in a number of radar navigational aids developed during the War. Another exhibit showed the radar equipment used in a modern bomber. This included the *H2S* equipment for obtaining a radar map of the ground over which the aircraft is flying, and the automatic gun-laying equipment used in the rear turret. The latter equipment enables a rear gunner to open fire at an approaching fighter which he cannot see visually. Some recent developments in the radar equipment for night fighters were also shown. The equipment enables the fighter to locate and follow an enemy bomber in the dark and to manœuvre into such a position that the pilot can see the enemy aircraft and attack it. A device was also shown which enables the radar information to be projected on to the pilot's windscreen so that he can at the same time view it and look out for the enemy aircraft.

Suppressed Aerials

As aircraft speeds increase, the drag of external aerials becomes more and more intolerable, and as sonic speeds are approached it is impossible to have external aerials at all. Methods of suppressing aerials by use of plastic fittings to the aircraft and by the use of slot aerials were illustrated. These methods represent considerable advances in aircraft aerial technique.

Ultrasonic Research

A number of applications of ultrasonics were illustrated, such as the measurement of ultrasonic absorption in metals as a means of determining the grain size, and the detection of obstacles and flaws by means of ultrasonic technique. The methods used were based on radar principles and employed pulses of ultrasonic energy.

Electronics for Atomic Energy

The exhibitions of the Atomic Energy Electronics Group included an electron accelerator operating on the synchrotron principle and producing electrons having an energy of 15 million electron volts. Various instruments were also demonstrated which are used for the measurement of radiations met with in nuclear physics research. In particular, a number of instruments called 'health monitors' were shown which are used to ensure that workers are not being exposed to an amount of radiation sufficient to cause appreciable bodily harm.

The Ministry of Supply School of Electronics gave a display of equipment illustrating the historical development of microwave technique. An exhibition arranged by the Engineering Department illustrated the development of new types of radio components designed to withstand extreme climatic conditions and also showed some of the latest types of miniature radio components which have been developed with the view of reducing the size and weight of airborne radio equipment. In addition, a number of films, including "RDF to Radar", were shown.

OBITUARIES

Mr. J. J. Shaw, C.B.E.

The death on May 23 of Mr. John Johnson Shaw at the age of seventy-four severs yet another link with the pioneers of the study of earthquakes in Great Britain.

J. J. Shaw was born at Gornal, near Dudley, educated at King Edward's School, Birmingham, and then apprenticed to an engineer. During the latter part of his engineering studies, he designed some gas and some steam pumps, and although he soon forsook his engineering to become a pawnbroker, he never lost his love for engineering. It was in the year 1908 that he read a newspaper article on the recording of earthquakes, and this encouraged him to visit Dr. John Milne, who, having retired from his professorship at Tokyo Imperial University, had settled in the Isle of Wight and set up a seismological observatory there. John Milne and J. J. Shaw became friends, and Shaw, on returning home, set up his first seismograph, which included as components an old treacle tin as drum, a wheat straw as pointer and a driving mechanism taken from an old German clock costing 1*s.* 11*d.* This instrument recorded some violent, world-shaking earthquakes, including the Messina earthquake of December 28, 1908, and with this early success and John Milne's encouragement, Shaw set about improving his instrument. The task became a life study, and in each Milne-Shaw seismograph made under Shaw's personal supervision some improvement on the previous one was embodied. Milne–Shaw seismographs are now working in many observatories throughout the world and are excellent for recording strong distant earthquakes.

Microseisms are now thought to be largely due to storms at sea. They gave ever-recurring trouble to the early observers, and Shaw suggested that data concerning them could best be obtained by the use of the tripartite seismograph station (British Association Seismological Committee Report, 1920), a method which in the hands of Father J. E. Ramírez at St. Louis, U.S.A., and later workers has given such good results.

Shaw, like John Milne, never lost an opportunity to make a friend for seismology. He fitted an electric bell to the seismograph system at his home in West Bromwich, so that he could be ready with instrumental results when any newspaper reporter rang him up about an earthquake. Reporters were often surprised at his perpetual cheerfulness over the telephone at any time of the day or night, and at the fact that his seismograph and his reference files often gave earlier information than their own telephone systems. A few years before the Second World War, Shaw was particularly pleased to set up one of his instruments in Selfridges' Store in London, so that any passer-by could see an earthquake being recorded should one occur at the instant he happened to be near the instrument. This instrument was suspended from one of the main structural steel pillars of the building, and since the steel went deep into the ground the pendulum recorded waves from distant earthquakes but was unaffected by street traffic or the movement of people in the store. This instrument is now in the Science Museum at South Kensington.

Shaw first became a member of the British Association Seismological Committee in 1914, probably having been proposed by his friend John Milne just prior to the latter's death in July 1913. John Milne had been honorary secretary of the Committee for many years, and Prof. J. Perry had taken over the duties of secretary as a temporary measure on John Milne's death. At Manchester on September 8, 1915, Prof. Perry resigned the secretaryship and J. J. Shaw took over. He continued as honorary secretary until July 26, 1946, and was a member of the Committee until his death. As a member of the Seismological Committee of the British Section of the International Union of Geodesy and Geophysics, J. J. Shaw took part in many international meetings and established a world-wide reputation as an instrumental seismologist. He was also a popular scientific lecturer of considerable renown in the Birmingham district, having an infectious enthusiasm for popular science in general and instrumental seismology in particular; being a kindly, forthright man, he made many friends. He was made C.B.E. in 1931, and awarded an honorary M.Sc. by the University of Birmingham a year later.

Mr. Shaw had suffered from knee trouble for some years, and on May 22 one leg was amputated; the operation was successful, but he had a relapse and died the next day. He will be missed by many people not only in his home town and district, but also by a wide circle of friends and acquaintances throughout the world. His son, Mr. Harold V. Shaw, is expected to continue the observatory.

ERNEST TILLOTSON

Dr. J. M. Dalziel

Dr. J. M. Dalziel, whose death was recently reported, was educated in Edinburgh and spent the first years of his career in South China as a medical missionary with the English Presbyterian Mission. His interest in natural history was evident even then. He eventually transferred to the West African Medical Service, where his work during many years took him to all the British West African Colonies. His greatest love was for Northern Nigeria in general, and the Hausas in particular. He was a good Hausa scholar, and also had a considerable knowledge of Fulani. He was a keen observer, and collected a number of new species, especially of Northern Nigerian plants, although he collected animals as well, and recorded their vernacular names. He tried to record the vernacular names and the uses of every plant he encountered, and his field notes were always most thorough and painstaking. His Hausa names of plants, with scientific equivalents, and often with derivations of the names, were published in 1916 as "A Hausa Botanical Vocabulary", an invaluable work, unfortunately now out of print, and in which the majority of the information given is still accurate. During that period Dalziel helped, with his field notes, in J. H. Holland's monumental "Useful Plants of Nigeria".

In zoology Dalziel was a keen bird watcher, as his little booklet "Bird Life round Accra" testifies. He also collected insects of importance as vectors in tropical medicine, and presented his carefully prepared specimens to the University of Edinburgh.

On his retirement from the West African Medical Service, Sir Arthur Hill, then director of the Royal Botanic Gardens at Kew, secured his services to help Dr. J. Hutchinson in the production of the "Flora of West Tropical Africa", a work which occupied the years 1923–36. It was a fortunate choice, for Hutchinson had a great knowledge of the African material in the Kew Herbarium, and Dalziel had a wide field knowledge in West Africa.

But it was the appendix to this flora, entitled "The Useful Plants of West Tropical Africa" (1937), which came to be Dalziel's *magnum opus*. The amount of information and local names he collected was amazing; there were 10,000 vernacular names from Nigeria alone. His information covered all the West African Colonies, including much information from the French West African Colonies. His thorough recording of the medicinal uses, for example, could only be done effectively at that stage by one who, like Dalziel, combined a thorough knowledge of both the plant life and the tropical diseases of the area, together with the necessary persistence and thoroughness in recording his own observations and those supplied to him by others. His correspondence during these many years of compilation must have been immense, and his critical faculty in dealing with it adequately must have been exceptional.

His work is a sound basis for all future work on the uses of West African plants, and he quotes all the authorities he used. This work was his main scientific work, done with endless care, at financial loss to himself, and with inadequate recognition in his life-time. Dalziel has put into the hands of educated Africans, as well as into those of European research workers, the requisite means for further research in the subject, which is of vital importance for the future welfare of West Africans themselves. In his work of recording the medicinal uses in particular, he has laid a foundation on which those of us who follow him can build with confidence.

F. R. IRVINE

Mr. G. L. Overton

MR. GEORGE LEONARD OVERTON, who had been keeper of the Department of Air and Water Transport at the Science Museum during 1926–35, died at his home in London on May 15. Born at Coventry on May 18, 1875, he was educated at Bradford Technical College and passed to the Royal College of Science, London, where in 1897 he graduated in physics and for a year held the post of assistant in the Astronomical Department.

In 1898 Overton was appointed to the then South Kensington Museum by competitive examination—in which he figured with high distinction—and was concerned with the presentation of various scientific subjects, notably time measurement, which for him was a hobby as well as a serious study. He was a fellow of the British Horological Institute and of the Physical Society, and in 1922 published a book on clocks and watches.

Overton had the analytical type of mind that is appropriate to museum work. He was a purist; not only in choice of words, but also in all matters pertaining to the restoration and preservation of exhibits. His regard for accuracy was so great that it tended to limit his output; but the official publications of which he was the author evinced a standard of precision rare even in technical literature.

A serious operation during the latter years of his service handicapped him, but it made his admirable custodianship of the collections for which he was responsible even more praiseworthy. He was one of the very few officers surviving who constituted the higher technical staff of the Science Museum on its separation from the Victoria and Albert Museum in 1909 and inception as a separate entity. The tradition so ably established by Overton and his contemporaries is the foundation upon which that national museum of science and industry is to-day erected. All who knew him, admired his knowledge, and experienced the kindness and generosity of his personal relationship, will deeply regret his passing.

M. J. B. DAVY

NEWS and VIEWS

Royal Society of London: New Foreign Members

ON May 27, Prof. D. W. Bronk, Prof. L. E. J. Brouwer, Prof. M. J. G. C. Caullery and Prof. L. C. Pauling were elected foreign members of the Royal Society of London.

Prof. D. W. Bronk is known not only for his own researches in biophysics but also as the director of the Eldridge Reeves Foundation for Medical Physics since its foundation in 1929. This Foundation forms a part of the University of Pennsylvania, and has acquired an international reputation under his direction and become a flourishing centre of research under his genial and skilled guidance and produced many distinguished pupils. In his own work, his early physical training shows in the precision and definition which he has brought to many biological problems. His particular contributions have been on electrical phenomena in nerve, following his work with Adrian in 1929 on the mode of discharge of impulses by motor nerve cells; he elucidated the functions of the carotid sinus and brought light to many problems of sensory physiology and of synaptic transmission. His work during the War was concerned with many applications of science to the Services, especially those relating to night vision. He was indefatigable in travelling to theatres of war and across the Atlantic as a co-ordinator of research between the laboratory and the field.

L. E. J. Brouwer, professor of mathematics in the University of Amsterdam, may be regarded, along with Cantor and Poincaré, as one of the founders of modern topology if only on account of his proof in 1911 that dimensionality is a topological invariant. Brouwer's life work has, however, been concerned with a theory of the nature of mathematics, which he put forward in its first state in 1907. This theory, known as intuitionism, denies in particular the universality of the law of the excluded middle, and has aroused much controversy.

Prof. Maurice Caullery is the most distinguished of French zoologists. During his long and active career, his students have included many of the present holders of zoological chairs in France and many other well-known biologists, including some in Great Britain. Until 1939, he held the chair of biology at the Sorbonne. He is a member of the Institut de France, member of the Belgian Royal Academy, foreign member of the American Academy of Arts and Sciences, LL.D. of St. Andrews, and has been exchange professor of Harvard University. He was president of the Société de Zoologie and of the Société de Biologie of France. He is president of the Permanent Committee of the International Zoological Congress, and honorary fellow of the Zoological Society and foreign member of the Linnean Society, which awarded him its Gold Medal in 1947. Caullery's 'Jubilé Scientifique' on his seventieth birthday in 1939 was the occasion of remarkable tributes to him and his work paid by many distinguished men of science. His contributions to zoology and general biology are remarkable for their positive and fundamental nature, their wide range and their stimulating character. He has made great contributions to parasitology in a variety of distinct groups of animals. It was he who discovered the Haplosporidia, a new order of Sporozoa. He worked out the life-cycles and relationships of parasites in many groups, particularly Crustacea, Turbellaria and Orthonectidæ. His studies have thrown much light on the biological relations of a parasite to its host.

Prof. L. C. Pauling, professor of chemistry in the California Institute of Technology, is distinguished for his researches on valency and on structural organic and inorganic chemistry. Through his profound knowledge of physics and mathematics he has been able to apply quantum mechanics to problems of chemical valency bonds. His comprehensive work is embodied in his book, "The Nature of the Chemical Bond" (1939), which is now recognized as a classic in chemistry. For this, and other cognate researches, Prof. Pauling was awarded the Davy Medal of the Royal Society in 1947.

Pontifical Academy of Science: New Members

The following have been appointed members of the Pontifical Academy of Science: Prof. J. M. Albareda-Herrera, professor of geology and director of the Institute of Edaphology, Ecology and Plant Physiology, University of Madrid; Sir Edward Appleton, secretary of the Department of Scientific and Industrial Research, London; Prof. E. Cruz-Coke, professor of physiological and pathological chemistry, University of Santiago; Prof. A. De Castro, professor of clinical medicine, University of Madrid; Prof. Edward A. Doisy, professor of biochemistry, St. Louis University School of Medicine; Prof. Herbert S. Langfeld, Stuart professor of psychology and chairman of the Department of Psychology, Princeton University.

Physiology at St. Andrews: Prof. P. T. Herring

The retirement of Prof. P. T. Herring from the Chandos chair of physiology in the University of St. Andrews brings to a close a long term of office, for he has occupied the chair for forty years. Prof. Herring was educated in New Zealand and later at the University of Edinburgh, where he came under the influence of Sir Edward Sharpey-Schafer, with whom he later collaborated. His first researches, published in 1908, concerning the development and structure of the pituitary gland, quickly gained recognition and gave the histological background for many of the earlier investigations on the function of this body. The colloid bodies he described are still referred to as 'Herring's bodies', and illustrations of his original preparations demonstrating the vascular bed of the pituitary are to be found in current textbooks. Later, the structure and function of the thyroid claimed his interest, and again he was responsible for contributing much valuable knowledge. Prof. Herring went to St. Andrews in 1908 with a reputation as a lecturer of great distinction, and during his tenure of the Chandos chair he has systematically developed the Department of Physiology and the teaching courses in accordance with current physiological thought. He himself has invariably undertaken the greater part of the teaching in his Department, and there will be many at this time who will recall his clear and stimulating lectures. In addition to his other duties, Prof. Herring has taken a large and vital part in the administration of the University of St. Andrews. He acted as dean of the Faculty of Science during 1921–39 and served as an assessor of the Senatus on the University Court for four periods. His colleagues and the many students who have gained so much from his kindly interest and help will wish him long years of quiet and happiness in his retirement.

Dr. A. E. Ritchie

Dr. A. E. Ritchie, who has been appointed to the chair of physiology in the University of St. Andrews in succession to Prof. P. T. Herring, has had a wide training, having graduated M.A. and B.Sc. in mathematics, zoology and physiology at the University of Aberdeen, and later, in 1940, obtained the M.B., Ch.B. in the University of Edinburgh. In 1945 he was awarded the Gold Medal for his M.D. thesis on the electrical diagnosis of nerve injury. His postgraduate work began when he was holding a Carnegie Scholarship in the Physiology Department of the University of Edinburgh. In that Department he has stayed, combining varied teaching experience with original research. His most important contribution, both to physiology and medicine, has been to design a reliable and relatively simple and compact electronic apparatus for the determination of strength-duration curves, thus converting a laboratory procedure into a practical clinical one. This apparatus is valuable in the diagnosis of nerve injury. Thus Dr. Ritchie's interests lie in the fields both of physiology and of clinical medicine. He has published a number of papers on muscle and nerve reactions both in health and disease, and has contributed an article on muscle reactions in the forthcoming "Encyclopædia of British Surgical Practice".

Proposed Central Publication of Scientific Papers

Mrs. Lucia Moholy, of 127 Sloane Street, London, S.W.1, writes: "In describing American methods of auxiliary publication in *Nature* of June 5 (p. 896), Mr. Watson Davis speaks with authority on the practical value of certain organised measures adopted in the United States to a larger extent than in some other countries. If corresponding methods have not yet attained comparable popularity in Great Britain, it does not follow that the question of systematically using and organising photographic reproduction to assist science and learning has not been taken care of. Not only have suggestions for extensive uses been put forward on many occasions, but also a specific study has been made of the part photographic reproduction can play in relation to Prof. J. D. Bernal's project. With the Royal Society's Scientific Information Conference in sight, a formal statement setting out the merits of these methods for alternative and supplementary services was drafted and, upon Prof. Bernal's request, submitted to the appropriate quarter. This followed an outline of these methods and their potential uses for the publication and distribution of scientific papers, at a meeting on Apr. 21, at the Society for Visiting Scientists. An earlier approach, also with specific reference to Prof. Bernal's project, was made at the Conference on the Publication and Classification of Scientific Knowledge, held at Trinity College, Cambridge, on October 25, 1947.

"The use of documentary reproduction for auxiliary publication, and its eminent suitability as an aid to science and learning in general, were the subject of two articles in *Nature* (157, 29, 38; 1946), where a new type of service was forecast to 'keep men of science currently informed of all the literature published on their respective subjects'. It was there, also, that the setting up of central agencies was suggested and interchange of services and close co-operation with bibliographical centres and scientific institutions was advocated. A memorandum to this effect was also submitted to Unesco (through the offices of its predecessor, the Conference of Allied Ministers of Education, 1945). In a paper read to the Royal Society Empire Scientific Conference, 1946 (Report, vol. 1, pp. 717–721), and another put before the Co-operation Committee of the Library Association in the same year, the setting up of a Central Office of Documentary Reproduction was recommended to act as a co-ordinating centre for Great Britain and the British Commonwealth and Empire; while a renewed appeal for the co-ordination of policy in Documentary Reproduction on a world scale was made to the Sixteenth Conference of the International Federation of Documentation in Paris, November 1946 (F.I.D. Communicationes, 13, Fasc. 4, 60; 1946). For the furtherance of these ideas, Mr. Watson Davis' letter has provided valuable evidence which should bring closer to realization some of the services for which the plans have been prepared in former years."

British Commonwealth of Nations Scientific Liaison Offices

The British Commonwealth of Nations Scientific Liaison Offices (London) have been opened on the third floor of Africa House, Kingsway, W.C.2. This is one of the measures to facilitate co-operation in the civil aspects of science within the Commonwealth decided on by the British Commonwealth Scientific Official Conference held in London in 1946. For a number of years several of the Commonwealth countries have maintained scientific liaison offices in London, and these, together with the ones now being established, will have their headquarters in Africa House. Each of these offices will continue to operate as in the past, retaining complete independence of action; but the convenience of occupying adjacent premises will facilitate co-operation between them on matters of common interest. For ease of reference to the group of independent offices as a whole, the title given above has been chosen, with the abbreviation B.C.S.O. (London) for common use. The offices taking part in the scheme are those of Australia, Canada, Central African Council, India, New Zealand, South Africa and the United Kingdom. Pakistan and the Commonwealth Agricultural Bureaux will be represented, and the Overseas Liaison Division of the U.K. Department of Scientific and Industrial Research will work in Africa House. In Washington the scientific liaison offices of the Commonwealth countries are associated under a similar scheme.

British Seismological Observatories

The Stonyhurst College Observatory has now ceased to record earthquakes, as has also the Royal Observatory at Edinburgh. Mr. E. W. Pollard has moved from the Isle of Wight to Dorking, Surrey, and hopes to set up his seismograph at his new home. He has presented a seismograph with mass 40 lb. to the County Secondary Grammar School at Newport, Isle of Wight, where the instrument has been set up and is being standardized. It is hoped to install good time-keeping apparatus shortly.

International Seismological Summary

Since the British Association meeting in September 1947, the United Nations Educational, Scientific and Cultural Organisation has given a substantial grant-in-aid to the International Union of Geodesy and Geophysics for the International Seismological Summary (see *Nature*, April 17, p. 616). The staff of the I.S.S., consisting of Mr. J. S. Hughes and two assistants, have been at work at Kew for more than a year now, and the full issue for the year 1936 has been produced and partly distributed. In addition, much work has been done on the Summary for 1937, portions of this being in the hands of the printers. We are informed by Dr. Wang Ging-Hsi, of the Natural Sciences Section of Unesco, that the Organisation will assist similarly with another grant in the present year.

Natural History Journals

One by one some of the journals whose light flickered and went out in 1939 are being revived. The latest is the *Scottish Naturalist* which now enters on its fifth stage under the joint editorship of Prof. V. C. Wynne-Edwards and Dr. J. W. Campbell. The first volume of the new series is mainly devoted to birds of Scotland. That country has also produced a new journal, *Scottish Zoo and Wild Life*; this has been inaugurated by the Zoological Society of Scotland for the benefit of its fellows and all who are interested in animal life. Cordial wishes for their success are extended to both these journals while naturalists everywhere will also wish to congratulate the *North-Western Naturalist* on reaching its twenty-first anniversary under the able editorship of Mr. A. A. Dalliman.

National Advisory Council for Education in Industry and Commerce

The following have been elected to serve on the Standing Committee of the National Advisory Council for Education in Industry and Commerce: Lieut.-General Sir Ronald Weeks (chairman), Sir Samuel Gurney-Dixon (vice-chairman), Sir Graham Savage, Mr. E. L. Russell, Mr. A. Ballard, Dr. Percy Dunsheath, Prof. F. H. Garner, Prof. R. G. Batson, Sir Robert Wood, Dr. T. J. Drakeley, Dr. H. Schofield, Mr. J. Wilson, Dr. J. E. Myers, Sir Charles Tennyson, Sir Arthur Smout, Mr. G. S. Heaven, Sir Arthur Fleming, Mr. B. J. Ewing, Mr. G. H. Lowthian, Mr. W. T. Mainwaring, Mr. M. F. Titterington, M.P., Mr. E. G. Gooch, M.P., Dr. F. C. Toy, the Hon. Josiah Wedgwood, Captain A. M. Holbein. Sir Samuel Gurney-Dixon was also elected vice-chairman of the Council.

Institution of Mining and Metallurgy: Awards

The Gold Medal of the Institution of Mining and Metallurgy, the highest distinction which the Council of the Institution has power to grant, has been awarded to Mr. G. Carleton Jones, resident director in South Africa of New Consolidated Gold Fields, Ltd., in recognition of his distinguished services to the gold mining industry of South Africa, and in particular to the development of the West Rand. Honorary membership of the Institution has been conferred on Dr. William Cullen, Dr. T. A. Rickard and Prof. S. J. Truscott, in recognition of their long and valued services to the mining and metallurgical profession and to the Institution. The "Consolidated Gold Fields of South Africa, Ltd." Gold Medal has been awarded jointly to Dr. Anthony Caplan and Mr. J. K. Lindsay, for their work on the effect of high temperatures on working efficiency in deep mines.

Institution of Civil Engineers: Officers

The following have been elected officers of the Institution of Civil Engineers for the Session 1948–49: *President*, Sir Jonathan Davidson; *Vice-Presidents*, Sir Reginald Stradling, V. A. M. Robertson, Dr. W. H. Glanville, A. S. Quartermaine; *Other Members of Council*, H. E. Aldington, Sir Stanley Angwin, Sir Donald Coleman Bailey, Prof. J. F. Baker, G. Baxter, W. S. Cameron, J. Chambers (India), H. F. Cronin, E. L. Everatt (Pakistan), A. Gray (Canada), A. C. Hartley, Prof. Douglas Hay, G. H. Humphreys, Sir Claude Inglis, L. Leighton, L. A. Mackenzie (South Africa), G. M. McNaughton, H. J. B. Manzoni, W. L. Newnham (New Zealand), Prof. A. J. S. Pippard, J. Rawlinson, W. P. Shepherd-Barron, T. H. Silk (Australia), J. C. L. Train, D. M. Watson, Sir Arthur Whitaker.

University of London: Appointments

The following appointments in the University of London have been announced: Prof. J. W. S. Blacklock, professor of pathology in the University of Glasgow, to the University chair of pathology tenable at St. Bartholomew's Hospital Medical College as from October 1; Mr. James Whillis, reader in anatomy in Guy's Hospital Medical School, to the chair of anatomy tenable at the School as from October 1; Dr. Hugh Ford, technical director, Paterson Engineering Group, to the University readership in applied mechanics tenable at the Imperial College of Science and Technology as from May 1.

The following titles have been conferred in respect of posts at the Colleges mentioned: professor of social studies in the University on Mrs. Barbara Wootton (Bedford College); reader in biochemistry in the University on Dr. H. W. Buston (Imperial College of Science and Technology); reader in biochemistry in the University on Mr. Wilfrid Lawson (Middlesex Hospital Medical School); reader in morbid anatomy in the University on Dr. D. M. Pryce (St. Mary's Hospital Medical School).

The degree of doctor of science has been conferred on Mr. B. H. Crawford, of University College.

Thirteenth International Congress of Zoology

The Chief Cashier, Exchange Control, Bank of England, states that a special allotment of the equivalent of £36 in foreign exchange will be provided to approved persons to enable them to attend the International Congress of Zoology in Paris during July 21–27. Anyone wishing to obtain this special allotment should submit an application on Form *T.2*, quoting the reference *I*/392 *EC* 902, through the medium of their own bankers, from whom the necessary forms may be obtained. The Bank of England authorities state that they would only be prepared to consider names sponsored by the Zoology Section, International Union of Biological Sciences, and therefore any applicants are advised also to notify the president of the Section, Dr. Edward Hindle, Zoological Society, Regent's Park, N.W.8.

Announcements

The Lord President of the Council has appointed the following to be members of the Chemistry Research Board of the Department of Scientific and Industrial Research for a period of four years: Mr. A. L. Bacharach, head of Nutrition Unit, Glaxo Laboratories, Ltd.; Prof. H. J. Emeléus, professor of inorganic chemistry, University of Cambridge; Prof. D. M. Newitt, professor of chemical engineering, Imperial College of Science and Technology, London.

The following have been appointed to the Advisory Council on Scientific Research and Technical Development, Ministry of Supply, which advises on the important scientific and technical problems with which the Ministry is concerned: Sir Howard Florey, professor of pathology, University of Oxford; Prof. J. L. M. Morrison, professor of mechanical engineering, University of Bristol; Prof. L. Rosenhead, professor of applied mathematics, University of Liverpool.

The Royal Astronomical Society wishes to direct the attention of authors to the fact that arrears of papers accepted for the *Geophysical Supplement* of the *Monthly Notices of the Royal Astronomical Society* have now been published. It is anticipated that in future the average delay between the acceptance and publication of geophysical papers will only be a few months. The arrears of papers accepted for the *Monthly Notices* are now all in print and will be published and distributed in the near future; after which the average delay between acceptance and publication should not be more than three or four months.

The Animal Health Trust has made a research grant to Mr. J. Steele, of Australia, for work at the Trust's Canine Research Station near Newmarket. Mr. Steele's work will be in connexion with the fundamentals of electro-cardiography as applied to domestic animals and with nervous diseases of dogs.

The Council of the Institution of Mining and Metallurgy is arranging a symposium on the "Refining of Non-ferrous Metals" to be held in London on July 7 and 8, thus preceding the Fourth Empire Mining and Metallurgical Congress. The papers to be presented will be issued as preprints, so that most of the time available at the meeting may be devoted to discussion. Further information can be obtained from the Secretary, Institution of Mining and Metallurgy, Salisbury House, London, E.C.2.

The third annual Electronics Exhibition organised by the North-West Section of the Institution of Electronics will be held in the College of Technology, Manchester, during July 20–22. There will also be an exhibition of scientific films arranged by the Manchester Scientific Film Society. Admission to the Exhibition will be by ticket only, obtainable from Dr. J. A. Darbyshire, 'Melandra', 1 Kershaw Road, Failsworth, Manchester.

A summer school for youth leaders is being held at Haywards Heath, Sussex, during July 26–August 1, under the auspices of the National Association of Girls' Clubs and Mixed Clubs. The theme of the conference will be "The Club Programme and Informal Education" and it will be directed by Dr. J. Macalister Brew. Further information can be obtained from the Education Secretary, National Association of Girls' Clubs and Mixed Clubs, 30–32, Devonshire Street, London, W.1.

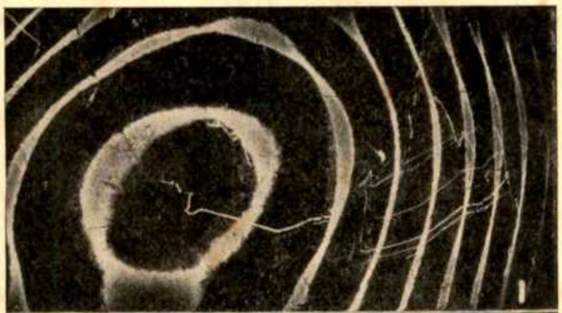
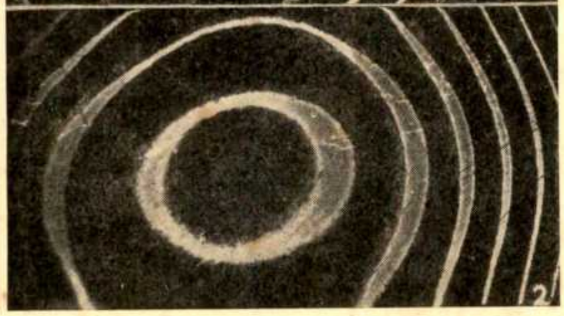
Application of Multiple-Beam Interferometry to the Study of Oscillating Quartz Crystals

WE have succeeded in applying multiple-beam interference methods to the study of the surface movements of oscillating quartz crystals, and the striking results obtained indicate that this has opened up a considerable field for investigation. The technique is simple. The quartz crystal (kindly prepared for us by Dr. W. G. Radley of the Post Office Research Laboratory) was polished to a slightly higher degree than that usually adopted for oscillators, in order to give sharp interference fringes. It was silvered very lightly on one side, and on the opposite face with a high reflecting silver layer. The high reflecting face was placed resting in contact with a silvered optical flat, and electrical connexion made (by gentle contact) between the lightly silvered face of the crystal and the silver layer on the flat. The two connecting leads were taken to an oscillator circuit. There were no constraints on the crystal.

On illumination with correctly collimated monochromatic light (5461 A.), sharp multiple-beam Fizeau fringes form in the air film between the surfaces of the crystal and the flat, providing the crystal is not oscillating. The particular crystal used was rectangular, 3 cm. × 1 cm., and about 3 mm. thick. The final optical polish was such that the face in contact with the flat had a slight curvature, as a result of which the field of view, when the crystal was not oscillating, was covered by a few sharp, yet highly dispersed approximately circular fringes. When oscillations are excited, the fringes take on the remarkable appearance shown in the accompanying reproductions. Fig. 1 shows about three-quarters of the crystal surface, the remainder (the left-hand quarter) being obscured by the particular microscope stage available. One can see in a striking manner the whole distribution of oscillation on the crystal surface. More than one type of oscillation can, of course, be excited, and in that illustrated in Fig. 1 it can be clearly seen that there exist clear-cut nodal lines which are roughly the diagonals of the rectangular crystal face, forming a St. Andrew's cross. Other secondary features are readily interpreted from the interferogram, the fringe-width at any point being an exact measure of the local amplitude of oscillation. In Fig. 2, an oscillation of another type is illustrated, different nodal regions being readily discernible. Under the particular excitation conditions employed here, observed amplitudes vary from zero to a maximum of about 750 A.





A remarkable feature is the extreme sharpness of the fringes in the nodal positions. It is evident that in these regions the fringes remain quite undisplaced over the length of the time of exposure (several minutes), and indeed from visual observation they appear to remain quite still indefinitely. An amplitude of oscillation of only λ/100 can certainly be detected even with the relatively imperfectly surfaced crystal used here. This quantity is about 50 A.; hence the nodal regions have certainly less amplitude than this small amount, if any at all, and may quite possibly be at rest to within the dimension of the crystal lattice spacing. It should be possible to test this conjecture by using the high-dispersion crossed fringe technique already in use in this laboratory; but such an approach requires a higher surface finish than that of the crystal used. When sufficiently well-worked surfaces become available, this sensitive technique will be adopted.

A surprising feature is the complete stability of the fringe pattern given by the oscillating surface, particularly when the sensitivity of the multiple-beam fringes is recalled. It is clear to us that an intensive programme of investigation is called for, and this is being undertaken. We intend also to attempt to extend the technique by the application of stroboscopic methods of illumination. We note here that some earlier attempts in this direction have been reported, using two-beam interference methods (see Vigoureux, "Quartz Oscillators and their Applications" (1939)), but of course, as is always the case, the sensitivity of a two-beam interference method is not to be compared with that of the far more powerful multiple-beam technique.

A fuller report, including details of measurements, will be communicated elsewhere at an early date.

Transfer Rates in Liquid Helium Films

THE superfluidity of liquid helium II can be very conveniently studied by making observations on the flow of the thick mobile films ('Rollin films'[1]) which cover all surfaces in contact with the liquid. In previous investigations of these films by Daunt and Mendelssohn[2], the rate of flow was observed to be almost independent of such factors as the pressure head or the height of the film, and varied only with the temperature, rising from zero at the λ-point to $7 \cdot 5 \times 10^{-5}$ cm.^{3}/sec. per cm. width of film below 1·5° K. We have extended these investigations and

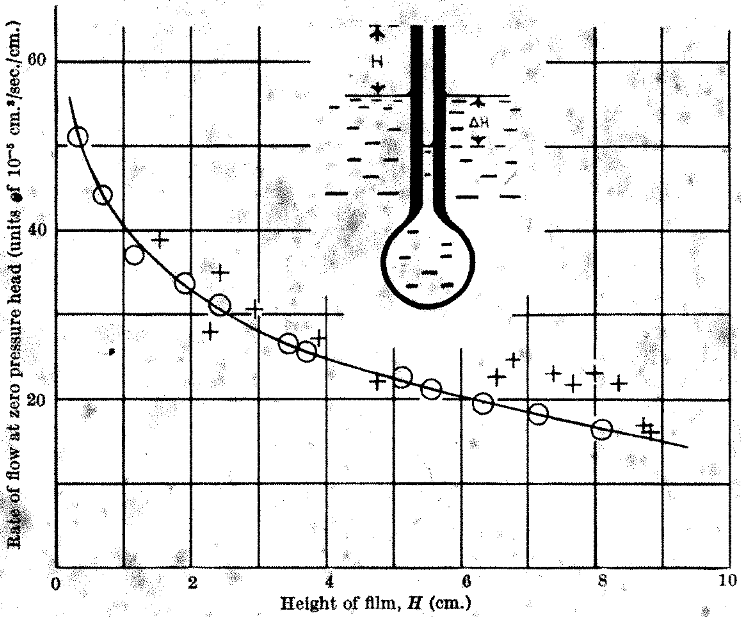

Fig. 1. ○, filling; +, emptying; temperature, 1·347° K.

have observed: (*a*) that with some experimental arrangements the rate of flow varies considerably with the height of the film; (*b*) that there is an effect which simulates a dependence upon the pressure head; and (*c*) that much higher rates of flow, up to 10^{-3} cm.^{3}/sec./cm., can occur.

In the first type of experiment an apparatus such as that shown in Fig. 1 was used. It consisted of a straight glass capillary of internal diameter 0·54 mm., open at its upper end and blown out into a closed bulb of diameter 3 cm. at its lower end. The capillary was partially immersed in a bath of liquid helium II, and that part of the glass surface protruding above the bath became covered with the film. When the vessel was raised or lowered, transfer took place through the film until the inner meniscus returned to its equilibrium position very close to the bath-level. The rate of filling was independent of the difference in height, ΔH, between the two levels, but the rate of emptying decreased as ΔH decreased in such a way as to suggest that the determining factor was not the pressure head but the height H of the top of the capillary above the higher of the two levels. During a filling the higher level was, of course, the bath-level which remained stationary so that H remained constant; but during an emptying the higher level, being the inner level, was falling rapidly and H was increasing as ΔH was decreasing. The rate of emptying extrapolated to $\Delta H = 0$ was approximately the same as the rate of filling; but both quantities varied rapidly with the height of the film, H, as will be seen from Fig. 1. This variation with H might be an effect depending upon the length of the film as in the case of viscous flow through tubes, but it is also possible, as suggested by Bijl, de Boer and Michels[3], that the thickness of the film is a function of height. The rate of transfer for a particular value of H varied in a complicated way with the radius of the capillary and even with the volume of the bulb, which suggests that the driving force was not a hydrostatic pressure but a temperature difference arising from the various thermal effects which are known to occur in liquid helium II.

It was, in fact, possible to initiate these high rates of transfer thermally, using the apparatus shown in Fig. 2. The small glass Dewar flask had a ground lip against which was pressed a glass cap with a ground flange. The only communication between the helium bath and the inside of the Dewar flask was via this ground joint, but the width of the gap was much greater than the thickness of the film. Heat was supplied electrically to the inside of the Dewar flask, so that the temperature there rose above the bath temperature and consequently liquid flowed into the flask via the film because of the thermomechanical effect[4]. The temperature difference associated with this flow was measured by means of two phosphor-bronze resistance thermometers, one inside the Dewar flask and the other in the bath. A set of readings was taken for a constant value of the film height, H, and the rate of flow was always measured when the flask was filling and the inner level was within a few millimetres of the bath-level. Fig. 2 shows such a set of readings for a film height of 0·9 cm. It will be seen that the flow became saturated

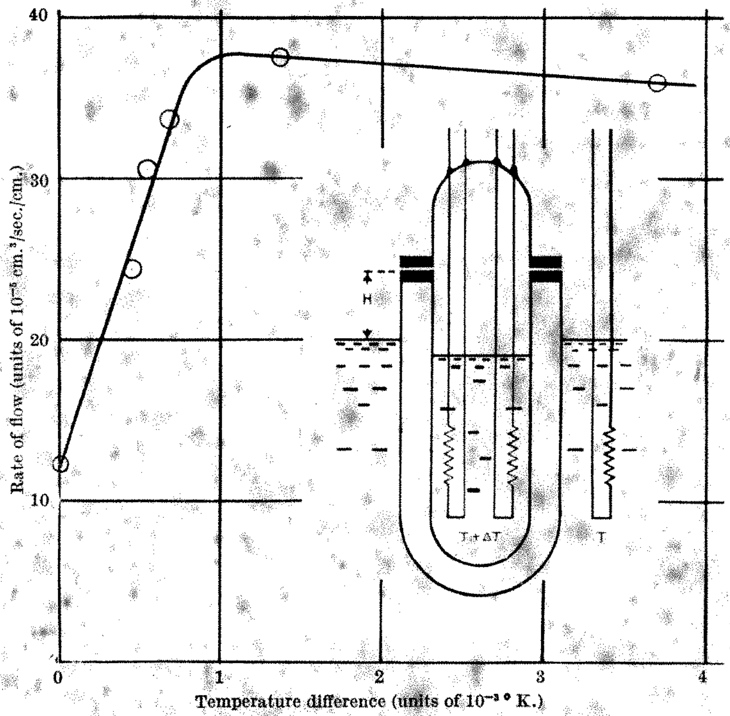

Fig. 2. Height of film, H, 0·9 cm. Temperature, 1·49° K.

at about 38 × 10^{-5} cm.^{3}/sec./cm. and then began to decrease slowly, presumably because evaporation of the liquid inside the Dewar flask was not entirely prevented by the ground joint. Preliminary measurements have shown that the maximum rate of flow is a function of the height of the film, being only about 26 × 10^{-5} cm.^{3}/sec./cm. for a film of height 4 cm. In order of magnitude these rates of flow agree satisfactorily with the data of Fig. 1.

It is worth noticing that saturation occurs at a temperature difference of approximately 10^{-3} ° K. which, according to H. London's[5] thermodynamic formula, corresponds to a thermo-mechanical pressure head of only 3 cm. of helium at this temperature. When no electrical power was supplied, a transfer of 12 × 10^{-5} cm.^{3}/sec./cm. was observed and was probably caused by unwanted heat inflow to the system. It was not possible, however, to decide whether this transfer took place under zero temperature difference or whether it required a temperature difference of the order of 10^{-4} ° K.

I should like to thank Prof. J. F. Allen for valuable help and discussion.

Diffraction of Light by Very High Frequency Ultrasonic Waves

IN two recent notes[1], we reported that ultrasonic waves of frequencies as high as 100 Mc./sec. were generated. The diffraction patterns produced by such waves were found to exhibit interesting features. Since then, by using a tourmaline plate and specially designed circuits, we have been able to push up this frequency to nearly 180 Mc./sec., and to study the diffraction effects produced when progressive waves of such high frequencies are maintained in a column of water. Results for the velocity of sound, measured at two different frequencies, are given below. In obtaining these, it has been assumed that the velocity in water is 1,504 metres per second at 15 Mc./sec. and 26·5° C. If the slightly higher temperature of the medium when the highest frequency is used is taken into account, it will be noticed that there is no dispersion of ultrasonic velocity.

It is well known that the first-order lines on both sides are easily obtained at normal incidence when low frequencies are used, and we have found in our earlier work that this feature persists even at 50 Mc./sec. Moreover, when the crystal is tilted, the line on the appropriate side increases in intensity and attains a maximum at the corresponding reflexion angle. The line on the opposite side decreases in intensity but generally does not vanish altogether, showing that if we regard the phenomenon as a reflexion, the angular region in which it occurs when moderate frequencies are used is not at all sharp. In the present experiments, we have made special arrangements to reduce the power supplied to the crystal at moderate frequencies to such an extent that the first-order diffraction lines obtained are as weak as those obtained at 177·2 Mc./sec. Even under such conditions, both lines appear at normal incidence and they exist simultaneously over practically the entire range as the tilt of the sound wave-front is varied from the reflexion position on one side to the reflexion position on the other.

Order of harmonic	Frequency, ν (megacycles per sec.)	Fringe width, d (cm.)	ν/d	Velocity (metres per sec.)	Temp. (° C.)
9	15·29	0·1237	123·6	1504	26·5
83	140·9	1·140	123·6	1504	26·5
107*	177·2	1·441	122·9	1511	27·9

* The plate distance in this case is slightly different from that adopted in the other two.

On the other hand, the diffraction patterns at the very high frequencies employed disappear altogether when the sound wave is exactly normal to the incident light. The crystal holder has to be tilted to the correct angle on one side or the other so that the first-order diffraction line on that side may appear. At these high frequencies, the first-order lines on both sides are never present simultaneously. It may even be said that the appearance of the first-order line is quite critical. The tilt angle measured in our experiments with different frequencies has been found to be in agreement with the value derived from the equation $\lambda/\lambda^* = 2\mu \sin \theta$. In accordance with this formula, we find that the sound wave-front has to be tilted from the normal position by 1° 29′ in the case of 177·2 Mc./sec. in order that the first-order line on one side may appear. So small a deviation as about 8′ from this position results in complete disappearance of the line. The wave-length of sound in water corresponding to 177·2 Mc./sec. employed in the present investigation is 0·000849 cm., which is only about fourteen times as large as the wave-length of sodium light.

A New Hot-Wire Vacuum Gauge

IT is known that the range of a hot-wire vacuum gauge may be extended to 10 mm. mercury pressure or above, if by some means the current supplied to

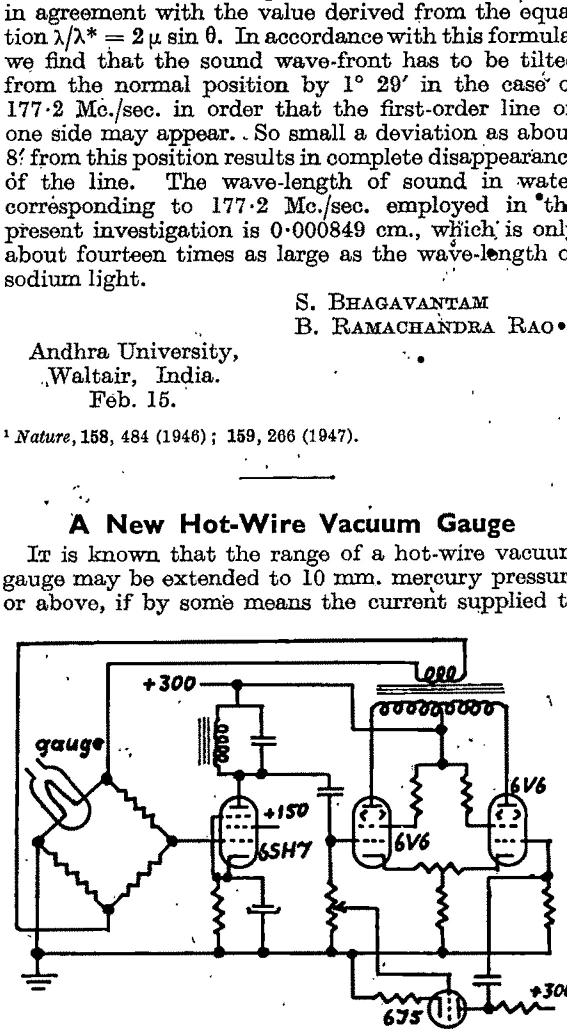

Fig. 1

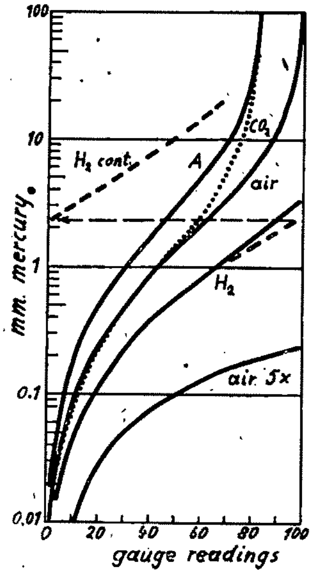

Fig. 2

the wire is increased with increasing pressure[1,2]. Attempts have been made to do this with the aid of automatic devices. Such a gauge becomes easier to handle, and there is then no danger of overloading. One of these circuits (suggested in principle by Mr. G. von Dardel) (Fig. 1) consists of an amplifier tuned on 800 c.p.s. A regenerative feed-back is provided by a bridge containing the hot wire. The amplitude of oscillations adjusts itself to keep the temperature of the wire approximately constant at all pressures. The amplitude is read by a diode circuit. Two ranges of sensitivity are provided. The output meter is protected from dangerous overloading by a rectifier which, however, distorts the readings slightly.

It is essential to use a very thin wire. An extended spiral of 0·01 mm. tungsten wire is employed here. The length is approximately 5 cm., cold resistance 90 Ω, working resistance about 120 Ω. The heating current ranges from 4 to 35 mA. The spiral is mounted inside a capillary in order to save space. Calibration curves are plotted in Fig. 2.

The gauge responds immediately to changes in pressure. In cases where for some reason it is not suitable to use a gauge with a fluid, the hot-wire gauge can be used.

Electron Tracks in Photographic Emulsions

Electron range. In a recent note[1], R. W. Berriman reported on a new photographic emulsion with which electron tracks can be recorded. Attempts have been made to relate energy and range of electron tracks in this type of photographic material, referred to as the *NT2a* plate. The electron tracks were obtained by exposing the plates to heavily filtered X-rays generated at increasing kilovoltages. The tracks were scanned under the microscope, and the number of grains of each track counted was plotted against the frequency of tracks. The curves so obtained show a shift of the maximum frequency towards greater numbers of grains with increasing kilovoltage. In a few cases where the tracks were at almost glancing angle to the plane of the plate, length measurements of the curved path of tracks were made. The maximum number of grains and lengths of tracks for each kilovoltage are shown in the accompanying table (columns 2 and 3).

1 kV.	2 Max. number of grains	3 Range in microns (curved path)	4 Schonland and Varder (calc. in microns)	5 Column 3 × 1·4 (curved path in microns)
35	13	8	6·1	8·4
50	18	14	10·6	14·8
65	16	—	16·7	23·4
69*	18	—	18·6	26·0
80	—	—	23·1	32·0
100	18	—	—	—
130	28	35	—	—
200	27	—	—	—

* This refers to monochromatic radiation (K_α of platinum).

It will be seen from this table that the maximum numbers of grains counted between 50 and 100 kV. are almost identical. A possible explanation might be the rising proportion of Compton recoil electrons, which have on the average a considerably shorter range than the photo-electrons. The range quoted in column 3 refers to the curved path of the electron tracks. The thickness of various metals necessary to stop electrons of different velocities was determined by Schonland[2] and Varder[3]. This was found to be dependent only on the mass per unit area. The range values of Schonland and Varder were converted into lengths in microns for the mass per unit area of *NT2a* emulsion, and these values are quoted in column 4. The curved paths in the metal should be on the average some 40 per cent greater than the thickness of the foil[4]. Column 5 shows the values of column 4 multiplied by 1·4.

From the values in column 4 and from the explanation regarding the constancy of grain numbers between 65 and 100 kV., it can be concluded that the maximum energy of electrons which can be recorded with the *NT2a* emulsion will be at about 80 kV. This figure might serve as a guide until more accurate measurements have been made by means of an electron spectrograph.

Fig. 2

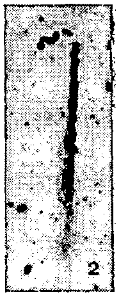

Fig. 1

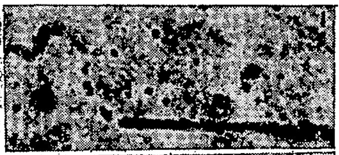

Fig. 4

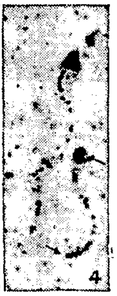

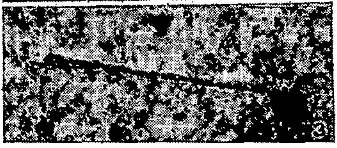

Fig. 3

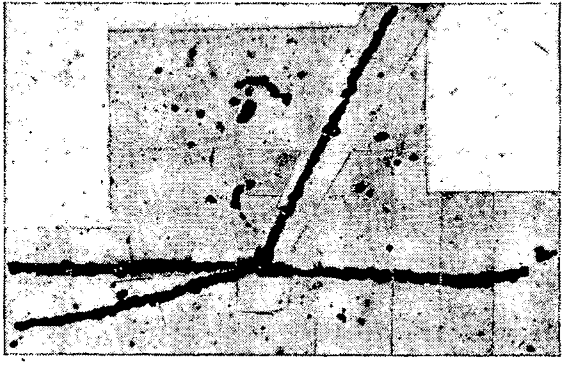

Fig. 5

Electron track records in radioactive decay. *NT2a* emulsions were soaked in dilute thorium and uranium nitrate solutions, and electron tracks were recorded at the origin of alpha-tracks. Figs. 1 and 2 show photomicrographs of alpha-tracks of uranium I with beta-tracks probably due to the decay of uranium-X_1. The beta-ray energy (Fig. 1) should, according to the table, correspond roughly to 35 kV. Fig. 3 represents an alpha-track due to thorium-C, and the beta-particle is due to the parent element thorium-B, which has been ejected before the alpha-emission. A second beta-particle is believed to be seen as being ejected from the same origin. This may be attributed to the beta-emission from thorium-C$''$. Fig. 5 is a photomicrograph-mosaic of a plane-projection of a three-dimensional radiothorium star at the origin of which an electron track is seen. The second electron track visible in this photograph may be the end of a track of an electron of higher energy arising from the same origin.

Auger tracks. While scanning the electron tracks it was observed that some tracks show clumping of grains at the beginning and at the end of tracks (see arrows in Fig. 4). This phenomenon can probably be attributed to the Auger effect. Although the specific ionization is greater at the end of the tracks, in some cases branching of short secondary tracks will be recorded in the emulsion by heavier ionizations at the beginning of the tracks.

I am indebted to Messrs. E. B. Kennedy and G. P. Cooke for their assistance in this work.

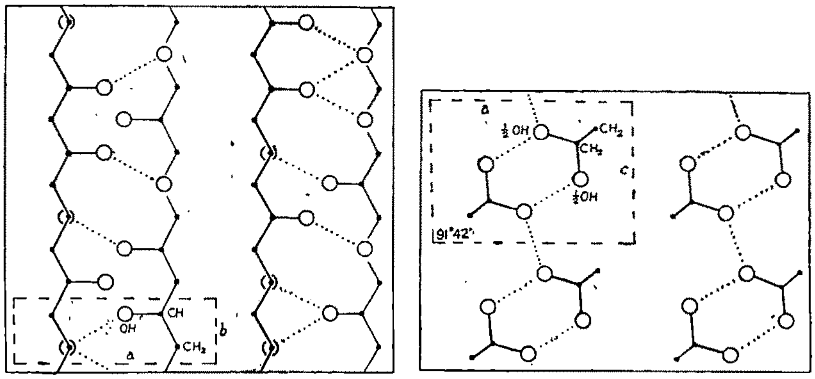
Crystal Structure of Polyvinyl Alcohol

IT has often been said (by me[1] as well as by others) that the molecular repeat distance (from X-ray diffraction photographs) of polyvinyl alcohol—2·52 A.[2]—indicates not only that the chain has a simple plane zigzag configuration, but also that all the hydroxyl groups (in the section of a molecule in one crystallite) lie on the same side of the zigzag plane. This is not necessarily true; so far as X-ray diffraction is concerned, the observed repeat distance is equally compatible with a molecular structure in which hydroxyl groups are randomly placed in left- and right-hand positions. This possibility was not considered until recently; it was assumed that the high degree of crystallinity of polyvinyl alcohol implied regularity of molecular structure. Recently, however, it has been found[3] that interpolymers of ethylene and vinyl alcohol are crystalline; thus hydroxyl groups may replace hydrogen atoms at random on a carbon chain without destroying crystallinity; the high crystallinity of polyvinyl alcohol cannot, therefore, be regarded as evidence against the idea of stereochemical irregularity in this molecule.



c-Projection *b*-Projection

DOTTED LINES, HYDROGEN BONDS

To determine whether the hydroxyl groups are randomly or regularly placed, the interpretation of X-ray diffraction patterns of polyvinyl alcohol fibres has been considered in detail. In agreement with Mooney[2], a two-molecule monoclinic unit cell is found to account for the positions of X-ray reflexions; this cell has $a = 7\cdot 81$ A., $b = 2\cdot 52$ A., $c = 5\cdot 51$ A., $\beta = 91^\circ\ 42'$; these figures agree fairly well with those of Mooney, who, however, gives $\beta = 90^\circ$. No structure embodying regular molecules gave correct relative intensities for the X-ray reflexions; all possible arrangements (including that proposed by Mooney) and all possible molecular parameters were considered. But a particular arrangement of molecules with hydroxyl groups randomly placed in left- and right-hand positions accounts in a highly satisfactory way for the entire X-ray diffraction pattern: calculated intensities agree very well with those observed. This arrangement has the symmetry $P2_1/m$ with C (of CH_2) at $0\cdot 190\ a$, $0\cdot 250\ b$, $0\cdot 806\ c$, C (of CH) at $0\cdot 277\ a$, $0\cdot 750\ b$, $0\cdot 708\ c$, half the oxygen atoms at $0\cdot 451\ a$, $0\cdot 750\ b$, $0\cdot 782\ c$, and the other half at $0\cdot 267\ a$, $0\cdot 750\ b$, $0\cdot 450\ c$. The arrangement, which is illustrated in the accompanying projections, may be described as a layer structure; a double layer of molecules is held together by hydroxyl bonds; between one double layer and the next the weaker Van der Waals forces operate. The hydroxyl bond distances (2·8 and 2·9 A.) are greater than in pentaerythritol[4] and resorcinol[5] (2·7 A.) and therefore the bonds are presumably weaker than in those substances; this is perhaps connected with the fact that owing to the random positions of the OH groups, some of the possible bonds are not made at all, while in other cases an OH group is faced with too many possibilities (up to four) of hydroxyl bond formation.

This is an example among high polymers of the sort of randomness which has been reported recently by Clews and Cochran[6] in a monomeric crystal (2-amino-4-methyl-6-chloro-pyrimidine); but in view of the difference of size of the hydroxyl group and the hydrogen atom, polyvinyl alcohol is a more extreme case. The implications in the theory of crystallization (or non-crystallization, as the case may be) of high polymers have been referred to in an earlier communication[3]. Here, I need only remark that polyvinyl acetate, from which polyvinyl alcohol is prepared, probably has a corresponding (stereochemically random) molecular structure, but, unlike polyvinyl alcohol, does not crystallize; this is presumably because the difference of size between acetate groups and hydrogen atoms is much too great for them to occupy equivalent positions in a crystal structure.

The Tollens Naphthoresorcinol Reaction for Uronic Acids

The mechanism of colour production in the Tollens test[1] for glucuronic acid is not definitely known, and since this reaction is frequently used for the determination of glucuronic acid in biological materials[2], an attempt should be made to understand its chemistry. Some of our preliminary results to this end are now reported here.

Since the reaction is carried out by heating naphthoresorcinol (1 : 3-dihydroxynaphthalene) and glucuronic acid in 5–6 *N* hydrochloric acid, furfural may be formed which may condense with naphthoresorcinol to give a pigment. We find, however, that furfural gives a different and less intense colour than glucuronic acid.

Mayer, Bloch and Chaffee[3] in a brief abstract suggested that the pigment of the Tollens test may be a xanthene derivative. Our observations (see below) appear to support this view, and the following mechanism is suggested for the Tollens reaction (cf. the formation of pyronine and phthaleine dyes).

Some of our observations were:

(*a*) Heating naphthoresorcinol, m.p. 119°, and *d*-glucurone, m.p. 176° (or *d*-galacturonic acid), together in the dry state at a low temperature, 100–120°, yields the same dark-blue solid as obtained in the Tollens reaction. In ethanol the blue solid obtained either way shows spectral absorption bands at 595, 335, 302 and 243 mμ.

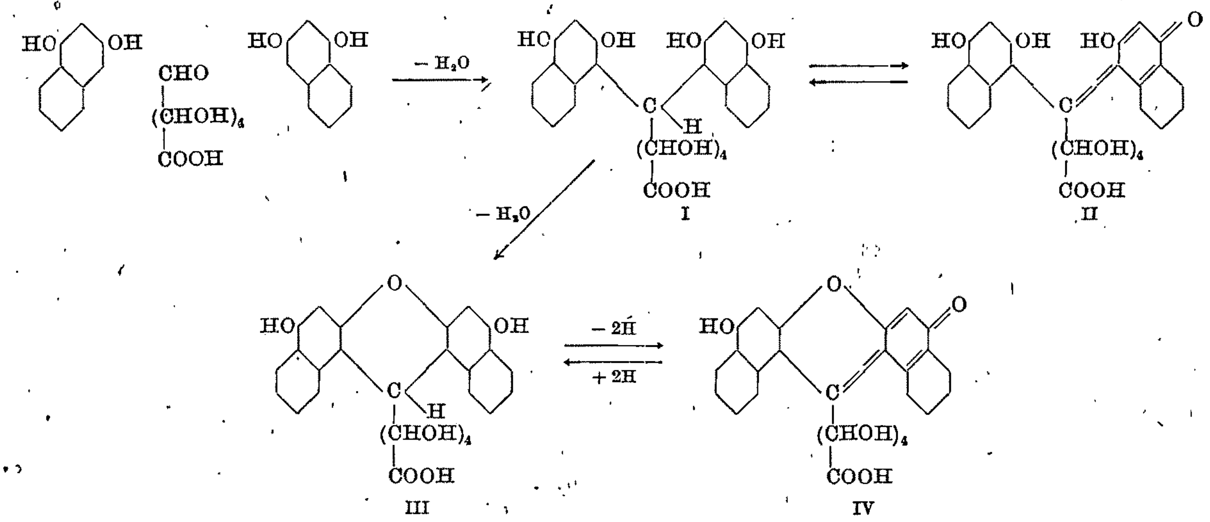
(*b*) If dry naphthoresorcinol and *l*-menthylglucuronide are heated together, no blue solid is obtained unless crystalline oxalic acid is added to the melt. This experiment suggests that the aldehydic group of the uronic acid must be free for pigment formation.

(*c*) The solid pigment is soluble in dilute alkali, from which it is precipitated by acid as dark-blue flocks, that is, it is acidic.

(*d*) A solution of the pigment is readily decolorized by sodium hydrosulphite, forming the leuco dye I or III, and the colour can be restored (to the quinones II or IV) by an oxidizing agent such as chloramine-*T*.

(*e*) If naphthoresorcinol is replaced in the Tollens reaction by monocyclic *m*-dihydric phenols such as resorcinol or orcinol, only very weak colours are obtained unless an oxidizing agent is also present. Thus if orcinol and glucurone are heated in 5–6 *N* hydrochloric acid, on extraction with amyl alcohol a weak green colour is obtained; but if the reaction is carried out in the presence of chloramine-*T*, a very intense green results. To obtain an intense colour with naphthoresorcinol an external oxidizing agent does not appear to be necessary, although Mayer, Bloch and Chaffee[3] state that the colour intensity is increased by potassium persulphate. It should be noted that the two possible formulæ, II and IV, suggested for the naphthoresorcinol pigment could form several resonance structures; these would tend to stabilize the pigment and render its production from the leuco-form relatively easy. This suggests that *m*-diols of polycyclic hydrocarbons such as anthracene-1 : 3-diol may be even better than naphthoresorcinol for detecting uronic acids, for in such compounds more resonance structures are possible.

We believe that the pigment of the Tollens reaction could be either a dinaphthylmethane (II) or a xanthene derivative (IV). We have found the isolated pigment difficult to purify, and we cannot as yet rely on elementary analyses for confirmation of the structures suggested. Analysis of a partially purified



sample gave C, 63·4; H, 3·8 per cent; $C_{26}H_{22}O_{10}$ (II) requires C, 63·2; H, 4·45 per cent; and $C_{26}H_{20}O_9$ (IV) requires C, 65·55; H, 4·2 per cent.

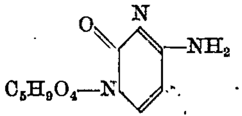
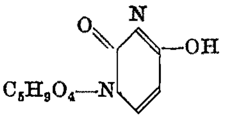
Separation of Pyrimidine Nucleosides by Synthetic Resin Ion-Exchangers

Four nucleosides—guanosine, adenosine, cytidine and uridine—are formed in the hydrolysis of yeast ribonucleic acid by aqueous pyridine, and Bredereck *et al.*[1] have described a method of isolating the nucleosides from the hydrolysate. Although this method is adequate for the production of guanosine and adenosine, we have been unsuccessful in isolating the pyrimidine nucleosides in the pure state and in good yield by this method, and believe this to be due to the method of isolation adopted by Bredereck.

In consequence, a technique has been developed for the separation of cytidine and uridine using a cation-exchange resin.



Cytidine



Uridine

Cytidine would be expected to be retained by a cation-exchange resin due to the basic amino-group ($pK'_b = 9{\cdot}78$)[2]. Uridine, on the other hand, would be expected to have little or no tendency to remain on the resin as the enolic hydroxyl group is acidic ($pK'_a = 9{\cdot}17$)[2]. 'Zeo-Karb 215' was selected for trial because of its strong proton-donating sulphonic acid groups and because of its stability to alkaline solution (*v. infra*). The above expectations were realized when aqueous solutions of cytidine and uridine were separately percolated down columns of 'Zeo-Karb 215'. In the former case, cytidine was afterwards eluted from the column by dilute aqueous ammonia.

A mixture of cytidine and uridine in aqueous solution (0·05 *M* with respect to each nucleoside) was therefore passed down a column of the same resin.

The percolate and aqueous washings were evaporated to dryness, giving crystalline uridine (*c*. 99 per cent recovery), m.p. 162–165° C. The column was eluted with *N*/10 aqueous ammonia and the eluate evaporated to dryness, giving crystalline cytidine (71–78 per cent recovery), m.p. 208–211° C.

An attempt is being made to obtain the pyrimidine nucleosides from deoxyribonucleic acid using the above technique. A fuller account of this work will be published elsewhere.

Isolation and Separation of the Pyrimidine Nucleosides of Yeast Ribosenucleic Acid

Improved methods have been sought for the isolation and preparation of the purine and pyrimidine nucleosides of yeast ribosenucleic acid as a preliminary to the study of the constitution of the nucleic acids of normal and malignant tissues.

Bredereck *et al.*[1] were able to prepare adenosine and guanosine by enzymatic or aqueous pyridine hydrolysis of the acid, and claimed to have separated cytidine and uridine. The yields of these latter were low and no characterization data were given. Gulland and Smith[2] failed to obtain cytidine by Bredereck's method, and the yield of uridine was augmented by deamination of any cytidine present. Isolation of the four nucleosides from the same nucleic acid sample has not hitherto been satisfactorily achieved even from hydrolysates of as much as 100 gm. nucleic acid.

Preliminary experiments showed that cytidine and uridine could be satisfactorily isolated and separated in one operation, not only from artificial mixtures, but also from the pyrimidine nucleoside fraction of the nucleic acid hydrolysate. Cytidine, having a basic amino group ($pK = 4{\cdot}22$)[3], is retained from dilute aqueous solution on percolation through a column of ion-exchange resin 'Zeo-Karb 215', activated by hydrogen ions. Uridine, on the other hand, with an acidic hydroxyl group ($pK = 9{\cdot}17$)[3] is not so retained.

Hydrolysis of 20 gm. yeast ribosenucleic acid (Pharmaco-Chemical Products Co.) with 50 per cent aqueous pyridine, by the method of Bredereck *et al.* (*loc. cit.*), gave comparable yields of guanosine (m.p. and mixed m.p. 237–240°) and adenosine (m.p. and mixed m.p. 228–229°). The residue was hydrolysed with 2 per cent sulphuric acid, and the liberated purine bases removed with silver sulphate. Excess silver ions were precipitated as silver sulphide, and sulphate ions as barium sulphate. Percolation of the solution (1 l.) through a column containing the minimum quantity of prepared resin and concentration *in vacuo* of the effluent and 1 l. water washings gave 2·4 gm. uridine, as colourless needles (m.p. and mixed m.p. 165–166°; α_D^{21} + 10° ± 2°; *c*, 1·6245 in water). Elution of the exchanger with 2 per cent aqueous pyridine gave 150 mgm. cytidine (crystallized as sulphate, m.p. and mixed m.p. 224–225° (dec.); α_D^{21} + 37·5 ± 2°; *c*, 1·498 in 1 per cent aqueous sulphuric acid).

A volumetric procedure has been developed for the estimation of dilute aqueous solutions of uridine and/or cytidine which may be used to determine the extent of elution or degree of exhaustion of the exchanger.

These experiments are described in detail in a paper submitted and accepted for publication in the *Journal of the Chemical Society* on January 20, 1948.

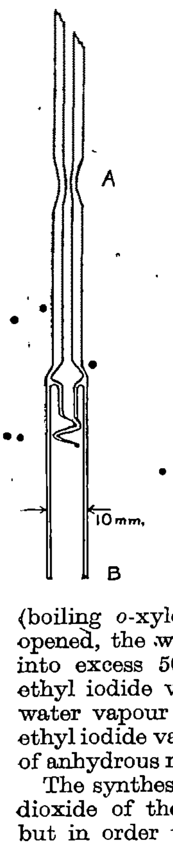
Microsynthesis of C^{14}-Labelled Ethyl Iodide

CARBON dioxide labelled with C^{14} can be converted in good overall yield to ethyl iodide by way of acetylene and ethylene on the scale of about 10 micromoles. Acetylene can be produced from carbon dioxide[1] in 90–95 per cent yield, and it may be reduced almost quantitatively to ethylene by the method of Traube[2,3], in which it is shaken for an hour with a large excess of freshly prepared chromous chloride solution at room temperature. The chromous chloride solution is prepared by the rapid reduction of a solution of 1 part green chromic chloride hexahydrate in 2 parts 25 per cent hydrochloric acid with zinc wool, until the solution turns almost a copper sulphate blue. About 0·4 ml. of this solution is pipetted into a glass reaction vessel (see diagram), frozen in liquid nitrogen and evacuated. The acetylene is condensed into the tube which is then sealed off at *A* and allowed to warm to room temperature. After agitation for an hour, carried out by intermittent rotation about its axis of the reaction vessel held horizontally, the vessel is sealed on to the high vacuum apparatus at *B* and the break-seal opened. All the dissolved gas is boiled from the chromous chloride solution, and ethylene condensed at liquid nitrogen temperature into a trap connected with a McLeod gauge, water and any residual acetylene being held back in a U-tube at liquid oxygen temperature. The yield in terms of standard gas volume is 96–98 per cent in this stage, and the remaining few per cent of acetylene can be recovered from the oxygen-cooled trap.

The direct addition of hydrogen iodide to ethylene is not easy, but can be carried out with about 90–95 per cent yield on the 10-micromole scale by sealing up ethylene with a few drops of saturated hydriodic acid in a tube similar to that used for reduction of acetylene but of about half the internal volume. The closed tube is then heated for one hour at 144° C. (boiling *o*-xylene). After the break-seal has been opened, the whole contents of the tube are distilled into excess 50 per cent caustic soda, from which ethyl iodide vapour can be recovered, most of the water vapour being held back at −78° C., and the ethyl iodide vapour finally dried over about 100 mgm. of anhydrous magnesium perchlorate for five minutes.



The synthesis is intended for use with radiocarbon dioxide of the highest obtainable specific activity; but in order to obtain a preliminary check on the yield in terms of radioactivity, several samples of C^{14}-labelled carbon dioxide of exceedingly low activity were converted to ethyl iodide by the method, this ethyl iodide being burnt and the carbon dioxide from it introduced into a Brown and Miller type β-counter[4]. It was found that whereas overall yields for $CO_2 \rightarrow C_2H_5I$ were about 80 per cent in terms of gas volume measurements, in terms of radioactivity they were generally some 10 per cent lower. About half the loss in radioactivity was found to occur in the stage $CO_2 \rightarrow C_2H_2$, and the other half in the stage $C_2H_4 \rightarrow C_2H_5I \rightarrow CO_2$. No loss of activity at all occurred in the stage $C_2H_2 \rightarrow C_2H_4$. In two particular experiments, the overall volume yields were 83·5 and 84 per cent, and the yields calculated from radioactivity measurements, 72 and 75 per cent. The activities of C^{14} available in each experiment were only about three times the background of the counter and were insufficient to pursue further the small losses, the first of which was probably due to an unidentified exchange reaction. In fact, the total amount of C^{14} available was 2×10^{-3} microcuries, of which half had to be used for calibration of the counter.

Catalytic reduction of acetylene to ethylene has been found to be possible on this scale, and yields are about 75 per cent. The method of preparation of the palladized palladium catalyst is critical, however, and it is easily poisoned. Chromous chloride reduction is much to be preferred.

We wish to acknowledge grants from the Therapeutic Research Corporation, the Royal Society and the Central Research Fund of the University of London, and to thank the Medical Research Council for grants and for a specimen of radioactive barium carbonate. Effect of Insulin on Intestinal Glucose Absorption in Alloxan Diabetic Rats

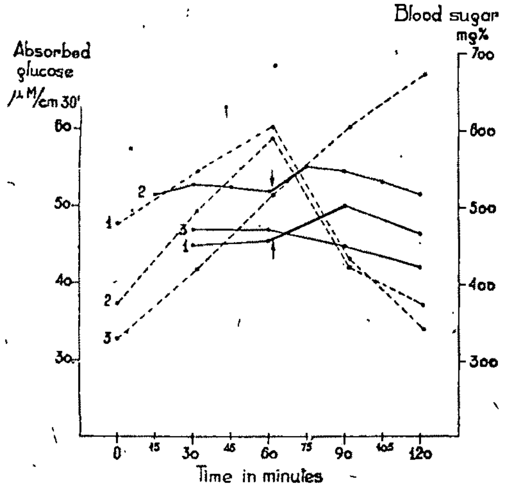
INTESTINAL absorption of glucose is increased in the diabetic rat[1,2]. According to Laszt and Vogel[2], this increase is not observed when alloxan diabetic rats are submitted to insulin treatment, suggesting that insulin has an inhibiting action on intestinal glucose absorption.

In the diabetic animal, as a consequence of the lack of insulin, changes are produced in the enzymatic systems, some of which might themselves modify absorption. To determine whether insulin has a direct influence on the mechanism of absorption, we have investigated the intestinal glucose absorption in alloxan diabetic rats before and after intravenous injection of insulin in the same animal, by the Sols and Ponz method of successive absorptions[3].

Diabetes was produced by intravenous injection of 5 mgm. of alloxan per 100 gm. body-weight. The animals were tested four to eight days after this injection. Previous to testing, a blood-sugar level greater than 300 mgm. per cent was recorded.

Within a period of 2½–3 hours, two or four absorption experiments (of 30 and 15 min. duration respectively) were done; then an intravenous injection of 2 units of insulin per 100 gm. body-weight was given, and immediately afterwards further absorption experiments, all other circumstances being kept constant. By way of control, the blood-sugar level was estimated periodically, usually once after each absorption experiment.

As a control of the absorption capacity in diabetic rats during the experimental period (about three



CURVES OF ABSORPTION (———) AND OF BLOOD-SUGAR LEVEL (– – –) IN ALLOXAN DIABETIC RATS.
(1) FOUR ABSORPTION EXPERIMENTS OF 30 MIN. DURATION.
(2) EIGHT ABSORPTION EXPERIMENTS OF 15 MIN. DURATION.
IN BOTH SETS AN ARROW MARKS INSULIN INJECTION. (3) CONTROL ANIMAL WITHOUT INSULIN INJECTION
THE INTERVALS BETWEEN ABSORPTION MEASUREMENTS (ABOUT 5 MIN. EACH) ARE NOT RECORDED

hours), several animals were examined in the same way, without insulin injection.

The accompanying figure shows three typical cases. These show that the immediate effect of insulin[1,2] is not to produce a decrease of intestinal absorption of glucose in diabetic rats, but rather a slight increase during the first half-hour; this contrasts with the tendency to decrease, with time, shown by diabetic animals[3]. In twelve animals, this increase showed an average value of 8 per cent.

We would emphasize that the maximal absorption does not correspond to a minimal blood-sugar value: one hour after insulin, the blood-sugar level is lower than after half an hour, whereas absorption is already returning to original values.

Respiratory Quotient of the Mammary Gland

DETERMINATIONS by the arterio-venous method of the respiratory quotient of the lactating udder of the goat[1,2] and cow[3,4,5] have given mean values greater than unity, which have been interpreted[1,2] as evidence of the formation of fat from carbohydrate. A feature of these studies, commented upon in at least one instance[5], has been the excessive variability of arterio-venous differences in oxygen and carbon dioxide and in the corresponding respiratory quotient values. No undue variability was, however, observed in a small series of determinations carried out on lactating cows in this laboratory[6], in which the blood samples were collected over mercury; in eight experiments in which no detectable hæmo-concentration occurred, the mean respiratory quotient was 1·25 ± 0·12 (95 per cent fiducial limits). Variance has also been diminished by working on anæsthetized goats[2], for which a mean respiratory quotient of 1·09 was obtained. This mean quotient can scarcely be regarded as significantly greater than unity; but it was raised to 1·18 by application of a correction (incidentally slightly incorrect[7]) for the carbon dioxide supposedly used for the synthesis of urea by the mammary gland. By contrast, values obtained on anæsthetized cows[4] could scarcely be considered as satisfactorily uniform.

The high mammary gland respiratory quotient indicated for the lactating gland by the arterio-venous technique is of obvious interest; but in view of the criticisms which this technique has to face[8,9], and since the high value has not always been confirmed by studies on perfused glands[3,5], it seemed desirable to investigate the question by the tissue slice method, which hitherto has not, so far as we know, been applied to the mammary gland. Accordingly we report below some preliminary results on the respiration and respiratory quotient of mammary gland slices from the lactating rat.

Satisfactorily reproducible slices of this difficult tissue were cut by the microtome of Stadie and Riggs[10], and the respiratory quotient determined by the method of Dickens and Šimer[11] in 3-hr. experiments in bicarbonate-Ringer (pH 7·4) containing 0·2 per cent glucose as substrate. The results of twenty-six determinations on slices from ten rats, given in the accompanying table, are satisfactorily consistent and in all cases much greater than unity. Taken together, they are appreciably higher than any of the mean (but not the extreme) values reported for the arterio-venous method. A few determinations by the direct Warburg method in phosphate-Ringer-glucose also gave results well above unity. On the other hand, six experiments (five rats) in bicarbonate medium in which no glucose was present gave a mean quotient of 0·78, so that it seems possible that fat and perhaps protein are being oxidized under these conditions.

The respiration figures are much higher than those reported for pieces (not slices) of rat mammary tissue by Kleiber, Smith and Levy[12] in so far as they are comparable; but our results, like theirs, indicate a tendency for the Q_{O_2} to increase as lactation advances and therefore as the milk yield increases[13] (mean values of $-Q_{O_2}$ (glucose) for slices from the three of our rats killed at three to six days and the remaining

RESPIRATORY QUOTIENTS OF RAT MAMMARY GLAND SLICES

Substrate	No. of rats	No. of determinations	$-Q_{O_2}$		R.Q.	
			Mean	Range	Mean	Range
0·2 per cent glucose	10	26	7·6 ± 0·4	3·5–11·5	1·54 ± 0·03	1·30–1·86
None	5	6	5·0 ± 0·4	4·1–6·3	0·78 ± 0·03	0·71–0·87

Rats: Hooded Norway. Medium: bicarbonate-Ringer (pH 7·4). Temperature: 37° C. Gas mixture: 95 per cent oxygen, 5 per cent carbon dioxide.

seven killed at 15–21 days *post partum* were respectively 5·6 and 8·4; $P = 0{\cdot}03$).

The validity of determinations of respiratory quotient on tissue slices extending over 3-hr. periods has been questioned[14], but we have evidence which indicates that the quotient is high from the outset, so that there is no reason to suppose that our values are far from the truth.

Our results point with satisfactory consistency to a quotient for lactating rat mammary tissue which is clearly much greater than unity, and thus lend needed support to the high values claimed for the lactating bovine udder on the basis of a technique which suffers from many disadvantages. Speculation in detail about the interpretation of these results in terms of postulated reactions occurring in the active mammary gland must await further work, but it seems reasonable to conclude that mammary tissue is noteworthy in its ability to effect considerable synthesis of oxygen-poor substances from carbohydrate *in vitro*. The interesting possibility, thus opened up, of using mammary gland slices for the study of fat synthesis *in vitro* is being further investigated.

We are indebted to the Agricultural Research Council for a research grant to one of us (T. H. F.).

Influence of Solvent Movement on Sedimentation

Due to the fact that in sedimentation the hydrodynamic volume of the particles moves towards the bottom of the vessel, the medium is caused to flow in an opposite direction. The sedimentation volume is the sum of the volume of the sedimenting particles and the volume of the medium which accompanies the particles.

In calculating the rate of sedimentation we use the following symbols: M_{I}, the molecular weight or particle weight of the sedimenting substance I; v_{I}, the partial specific volume of I; c_{I}, the concentration of I in gm./cm.³; Φ_{I}, the specific sedimentation volume of I in cm.³/gm. substance I; v_1, the partial specific volume of the solvent 1; x, the distance from the axis of rotation; ω, the angular velocity; $s_{\text{I}} = \frac{1}{\omega^2 x} \times \frac{dx_{\text{I}}}{dt}$ = the sedimentation constant relative to the walls of the vessel; $\sigma_{\text{I}} = \frac{1}{\omega^2 x} \times \frac{dX_{\text{I}}}{dt}$ = the sedimentation constant relative to the free solvent; A, the cross-sectional area of the cell. (These magnitudes should be corrected for the shape of the cell so that they hold for a vessel with parallel walls, and for the changes in density and viscosity with pressure, and for the change in the centrifugal force with x.) The sedimentation volume per second is $c_{\text{I}}\Phi_{\text{I}} \frac{dx_{\text{I}}}{dt} \times A$, and the cross-sectional area for the stream of solvent is A minus the area $c_{\text{I}}\Phi_{\text{I}} \times A$ of the sedimenting particles on this level. Therefore

$$\frac{dX_{\text{I}}}{dt} = \frac{dx_{\text{I}}}{dt} - \left(- \frac{c_{\text{I}}\Phi_{\text{I}}}{1 - c_{\text{I}}\Phi_{\text{I}}} \cdot \frac{dx_{\text{I}}}{dt}\right) = \frac{1}{1 - c_{\text{I}}\Phi_{\text{I}}} \cdot \frac{dx_{\text{I}}}{dt}. \qquad (1)$$

The centrifugal force per mol is $M_{\text{I}}\left(1 - \frac{v_{\text{I}}}{v_1}\right)\omega^2 x$ if the accompanying solvent has the same density as the free solvent, which generally, and particularly with pure solvents, is very nearly correct. The frictional force per mol is $f \frac{dX_{\text{I}}}{dt}$. Equating these two forces we get,

$$M_{\text{I}}\left(1 - \frac{v_{\text{I}}}{v_1}\right)\omega^2 x_{\text{I}} = f_{\text{I}} \cdot \frac{dX_{\text{I}}}{dt}, \qquad (2)$$

$$M_{\text{I}} = \frac{f_{\text{I}} \cdot s_{\text{I}}}{\left(1 - \frac{v_{\text{I}}}{v_1}\right)(1 - c_{\text{I}}\Phi_{\text{I}})}. \qquad (3)$$

In certain circumstances, Φ_{I} does not change with c_{I} and the concentration in front of the boundary is constant, σ_{I} is independent of c_{I}. Then we have from (1)

$$s_{\text{I}} = \sigma_{\text{I}}\,(1 - c_{\text{I}}\Phi_{\text{I}}). \qquad (4)$$

In this case s_{I} is a linear function of c_{I}, and the value extrapolated to infinite dilution is σ_{I}. From the slope of the graph of s_{I} against c_{I} we can calculate Φ_{I}. In Table 1 values of Φ_{I} are given for some proteins.

TABLE 1

Protein	Φ_{I}	Calculated from measurements made by
Serum albumin (horse)	14	v. Mutzenbecher[1]
,, ,, ,,	10	McFarlane[2]
,, ,, ,,	10	Johnston and Ogston[3]
Serum globulin (horse)	12	v. Mutzenbecher[1]
,, ,, ,,	9·6	McFarlane[2]

The stream of liquid causes the sedimentation peak (dc/dx as a function of x) to have a steeper slope towards the solution than towards the solvent when the diffusion is normal and the substance monomolecular. This means that the sedimenting boundary, obtained from the first moment of the peak, does not correspond to the maximum. If $c_{\text{I}}\Phi_{\text{I}}$ is smaller than about $0{\cdot}1$, dx_{I}/dt can be calculated from the maximum point and c_{I} put equal to half the concentration of I in that part of the solution where the concentration is unaffected by the diffusion.

The sedimentation volume also has an effect upon the areas of the sedimentation peaks. Let c_{I}° and c_{II}° be the original concentrations of two macromolecular substances, of which I moves faster than II, and $\varphi_{\text{I}}^{\text{II}}$ the volume of 1 gm. of substance I and the solvent, which moves together with it and which is not combined with II. Behind the faster boundary $c_{\text{I}} = 0$ and

$$c_{II} = \frac{c_{II}^{\circ}}{1 - c_I^{\circ}\varphi_I^{II}} \quad (5)$$

in the part between the two boundaries where the concentration is constant. Hence $c_{II} > c_{II}^{\circ}$. If we take the amount of I before the faster sedimenting boundary as the difference $\Delta c_I = c_I^{\circ} + c_{II}^{\circ} - c_{II}$, as is usually done in the determination of concentrations from sedimentation diagrams, we get a smaller value than c_I°. From (5) or Δc_I, it is possible to calculate φ_I^{II}.

The same conditions are also obtained if II is a low molecular substance, 2, and this is the explanation for the fact that c_I as calculated is smaller than c_I° in many protein sedimentations. In this case we get the inner solvation, while $\varphi_I^{II} - v_I$ is the total solvation in cm.³ per gm. of substance I. The inner solvation of cellulose nitrate has been determined by H. Sihtola and T. Svedberg[4] by sedimenting cellulose nitrate in a mixture of a solvent and an indifferent liquid.

If the molecules are dissociated into ions, we must also allow for the electric forces. If there are more than two substances dissolved, the calculations are made in the same way but are more laborious.

In Table 2 some values of φ_I^{II} are given.

TABLE 2

Protein I	Protein II	φ_I^{II}	Calculated from measurements made by
Serum albumin	Lactoglobulin	11	Pedersen[5]
" "	"	11	Johnston and Ogston[3]
Serum globulin	"	7	"
" "	Serum albumin	10	"
" "	" "	12	McFarlane[2]

Every value is the mean of at least three determinations at different concentrations. From Tables 1 and 2 it is seen that Φ_I is nearly the same as φ_I^{II}, but the values are not good enough for the formulation of definite conclusions. New measurements and a more detailed discussion will be published later.

To Prof. The Svedberg I wish to express my thanks for the privilege of working at this Institute. I am indebted to Prof. Ole Lamm for his interest in this work; I also wish to thank Mr. Evald Hellman for many stimulating discussions.

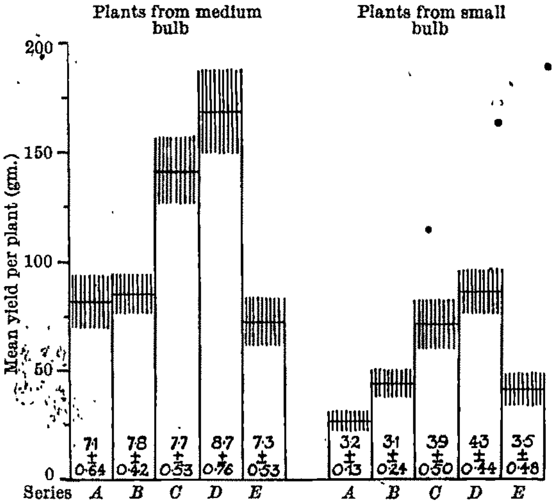
Bulb Formation in the Shallot

As a medium for studying the process of bulb formation, the shallot has certain advantages. It is normally grown from sets, and provided a suitable non-flowering strain is chosen any possible confusion between the effects of treatments used on flowering and bulbing is avoided. In our experiments shallot bulbs of two sizes (medium, mean weight 10·59 gm., and small, mean weight 3·12 gm.) were subjected to the following storage treatments during the winter preceding planting: (*A*) ordinary (laboratory) storage; (*B*) low temperature (0–4°) storage; (*C*) high (88 days at 30°) followed by ordinary temperature; (*D*) low (88 days at 0–4°), followed by ordinary temperature; (*E*) ordinary (88 days), followed by low temperature (71 days at 0–4° C.).

Plants of series *C* were noticeably slow to come into growth, and the plants from the medium-sized bulbs were always more vigorous than those derived from small bulbs. By mid-June the plants of series *C* and *D* were beginning to bulb (the 'low-temperature plants' being slightly more advanced than the 'high-temperature' ones), while all other series were in an advanced state of bulbing. The plants of series *C* and *D* continued to carry vigorous green upright foliage, and were not fit to harvest until August 26, 1946, whereas the other plants were fit to harvest five weeks earlier. Yield data are shown below. It was noticeable that the produce of series *C* and *D* included many very asymmetrical bulbs. These consisted either of one large and one or more smaller bulbs, or of two or more bulbs almost equal in size, invested in a common set of scales.

With both sizes of planted bulbs the treatments have affected bulb growth, but there is some divergence between the results for the plants from the small- and medium-sized bulbs. In both sets of material, series *C* and *D* have given the highest yields. This increased yield is effected by an increase in the weight of the individual bulbs. Treatments *B* and *D* had no effect on the plants from the medium-sized bulbs, but an appreciable effect on those from the small bulbs.



COLUMNS REPRESENT MEAN YIELDS PER PLANT AND THE VERTICAL HATCHING THE STANDARD ERRORS OF THE MEAN. FIGURES IN THE COLUMN REPRESENT THE MEAN NUMBER (WITH STANDARD ERRORS) OF BULBS PER PLANT

In a subsidiary experiment in which bulbs were stored at high temperature throughout the whole winter, a similar increase in yield and individual bulb-weight was obtained; although in this case the treatment caused an increase in the number of bulbs per plant—probably because common investing scales rubbed off many of the asymmetrical bulbs after drying, so that two or three separate bulbs resulted.

Bulbing in onions is a phenomenon the initiation of which is to a large extent controlled photoperiodically[1], but depending also on the temperature[2–5] and nitrogen supply[6] as well as on the variety. The critical photoperiod differs according to whether the plants have been derived from sets or seeds, and in the former case the growth and bulbing of the plant are affected by the storage treatments to which the sets have been subjected. Heath and his co-workers[2-5], concerned especially with the effects of storage treatments of onion sets on the 'bolting' of the resulting plants, and confirming and extending the results of earlier workers[1,7], found that high-temperature storage given throughout the winter, or for the last eight weeks, delays ripening, and gives larger yields, whereas high-temperature storage for the first eight weeks has no such effect. These treatments also reduced the incidence of 'bolting', as did storage at 0° either for the whole or the first eight weeks of the winter. The effects of storage treatments on bolting and bulbing were difficult to disentangle; but Heath and Holdsworth[4] concluded that the high-temperature treatments suppress bolting and affect bulbing separately.

So far as the treatments given here parallel those used by Heath in the treatment of onion sets, the results are similar; but with a non-flowering strain of shallot, there is no possibility of any confusion between the effects of the several storage treatments on flowering and bulbing. With the shallot, therefore, we can be sure that we are dealing with a primary effect on bulb initiation and swelling, and not with some secondary effect on these phenomena that operates through the suppression of flowering. If, in the shallot, as in the onion, bulbing is controlled photoperiodically, the effects of these storage treatments would be at least partially explained if their primary effect was in some way to increase the critical photoperiod necessary for bulb initiation. The shallots are grown during a period of lengthening days (April–June), and the effect of an increase in this critical photoperiod would be to delay the onset of bulbing. Further[1], with onions, the greater the excess of the photoperiod experienced over the critical photoperiod required for bulb initiation, the more rapid are the ripening processes. Hence, if the critical photoperiod is increased, but is still less than the photoperiods experienced after bulbing has begun, the difference between the critical and the experienced photoperiods will be reduced, and the processes of bulb ripening retarded, that is, the period of bulb-swelling extended. Delayed bulb initiation, a prolonged period of bulb swelling and delayed ripening are the precise effects on the resulting plants of storage throughout the winter, or for the first part of the winter at 30° C., or for the first part of the winter at 0–4° C. (or for the whole storage period at 0–4° C. with small bulbs) of shallot bulbs before planting. The data available do no more, however, than permit the suggestion that the storage treatments operate on the lines indicated, affecting in some way the critical photoperiod required for the initiation of bulbing in the resulting plants.

Streptococcus fæcalis in *E. histolytica* Infections

BACTERIOLOGICAL studies conducted upon a series of cases of relapsing amœbiasis showed that changes occurred in the relative distribution of organisms in the fæces during the active stages of the disease[1]. One particular change was the abnormal prevalence of enterococci in dysenteric exudates. In most cases, these enterococci were identified as *Streptococcus fæcalis*.

When a 1 per cent glucose-broth culture or culture-filtrate of certain strains of *Streptococcus fæcalis* was added to a phosphate-buffered suspension of *E. histolytica* in equal volume, the amœbæ were observed to disintegrate in one or two hours. This effect was a specific result of the growth of *Streptococcus fæcalis* in peptone media containing glucose, and was due apparently to some substance or substances formed during the fermentation of glucose. When glucose was fermented by growing cultures of coliform organisms or staphylococci, no such action was observed.

The complete identity of the metabolites which are toxic to *E. histolytica* has not as yet been ascertained, but the properties are consistent with a heat-stable, water-soluble substance not readily adsorbed on surfaces. Lactic acid[2] shows a similar type of activity against *E. histolytica in vitro* in concentrations of $0{\cdot}05\,M$; this concentration is readily attained in glucose-broth cultures of *Streptococcus fæcalis*, and removal of lactic acid from such cultures by ether-extraction almost eliminates their activity. The effect is not a direct consequence of changes in the hydrogen ion concentration of the media, though the action of lactic acid increases as the *p*H falls, and lactates, which are inactive at *p*H 7, show activity at *p*H 5. It is probable, therefore, that the principal toxic metabolite is lactic acid.

An effect was also observed *in vivo* when young rats, experimentally infected with *E. histolytica* by the method of Jones[3], were fed with living cultures of the appropriate strains of *Streptococcus fæcalis*. The degree of amœbic infection was consistently lowered, and when cultures of the two organisms were mixed before inoculation of the rats *E. histolytica* lost its infectivity within one hour.

Enterococci of the *Streptococcus fæcalis* group are normal members of the intestinal flora of man and certain animals, especially in the small intestine. Their prevalence in the colon becomes increased during the 'hurry' of the small intestine caused by diarrhœa. As a result of this, *E. histolytica* becomes more closely associated with *Streptococcus fæcalis* in the colon during the active stages of amœbiasis. It is possible, therefore, that the process described above plays a part in the natural history of an amœbic infection.

Sex Reversal in Copepods

BETWEEN February and June 1947, 20·5 per cent of the males, 3·7 per cent of the females and 0·3 per cent of the copepodids of *Pseudocalanus elongatus* Boeck, collected from six stations between Flamborough Head and the Dogger Bank, were found to be parasitized by *Blastodinium contortum hyalinum* Chatton. Almost all the observed parasites were found to be in the tetrablastic or a later stage, with a length of 440–560 μ. They occurred singly in the vast majority of cases, but very rarely two individuals were found in the same *Pseudocalanus*. As the material was unstained, it is likely that most of the earlier stages of the parasite were overlooked, particularly in the younger stages of the copepodids, and that the proportion of infected individuals was really higher than that given.

Chatton[1] states that the presence of *Blastodinium* causes the castration of the host without, however, this affecting its external structure; on the other hand, it brings about a comparative reduction in its maximum size. He did not find any parasitized adult males, and thought that the parasite arrested the development of the last copepodid by inhibiting the final moult. Chatton recorded infection of *Pseudocalanus* sp. from the North Sea.

In the parasitized material dealt with here, while the stage V male and female copepodids and the mature females had normal external features, there were present abnormal individuals. Some of these showed a full development of the female abdomen, vulva and all other characters such as antennæ, but with the presence of a fifth pair of legs. The legs were in a state of development corresponding with that in one of the male copepodid stages. Contrary to Chatton, I have found these infected copepods to be, if anything, slightly larger than the comparable non-parasitized individuals. I have recorded to date three individuals in this category which had an attached spermatophore (Fig. 1).

I have found also several infected individuals such as that shown in Fig. 2, in which the female type of abdomen is not fully formed, showing the presence of the vulva, but with the abdominal segments 1 and 2 not completely fused together. The proportions of the remaining segments are typical of the male sex. These individuals possess, moreover, a pair of fully formed male fifth legs. The contained parasite measures about 310 μ in length and is in either the di- or triblastic stage.

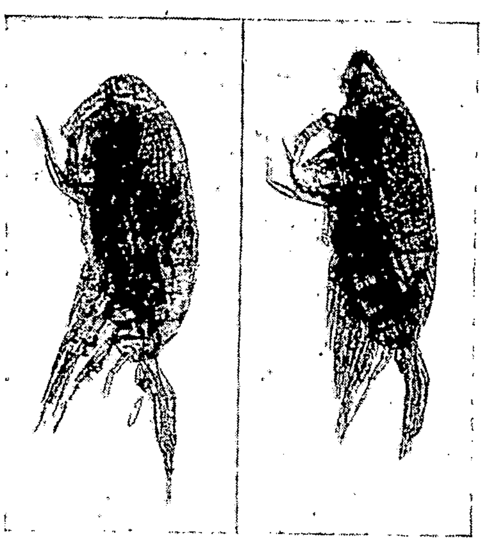

Fig. 1 Fig. 2

Pseudocalanus elongatus BOECK FROM THE SOUTHERN NORTH SEA, PARASITIZED BY *Blastodinium contortum hyalinum* CHATTON. PHOTOMICROGRAPHS OF TWO UNTREATED AND UNMOUNTED INDIVIDUALS PRESERVED IN FORMALIN. LENGTH OF CEPHALOTHORAX: FIG. 1, 950 μ; FIG. 2, 920 μ. MAG. × 40

These observations suggest that the parasite exercises no effect on the morphology of the female sex of the host, and that the last copepodid stage passes on to the fully formed but castrated individual. In the male sex, however, the parasite at some stage in its growth is able to arrest the development of the male characters of the copepodid (externally the fifth pair of legs), while in the final ecdysis it causes the copepod to undergo sex reversal and become a superficially mature but sterile female. The presence of the fifth pair of legs remaining in a state of development comparable to that in the animal's previous stage is the only indication of the original male sex.

It appears most likely that the individual of Fig. 2 became parasitized first at a later stage in its development than usual, and that it was able to reach the fully mature male stage before the parasite could exercise control over its morphology. Whether the individual could show the complete external sex change described when the parasite approaches its maximum size remains to be seen.

It is apparent that the abnormal 'females', under the influence of the parasite, have undergone complete sex reversal, for it has been shown that males find them as attractive as normal females and effect copulation (*vide* Fig. 1). The sex reversal is, however, virtual, not absolute, as according to Chatton the copepods are castrated.

Although the incidence of infection has been shown to be considerable, the castration which occurred does not seem to have caused any substantial drop in the population of *Pseudocalanus*, as large numbers of uninfected juvenile forms were found in June at the end of the period.

I am indebted to Colonel Seymour Sewell for suggesting the possible identity of my parasite and also for referring me to Chatton's paper.

Evaluation of Herbage for Grazing

IN the numerous published accounts of digestibility trials with cut herbage, the assumption has been made[1] that the herbage fed represents that which grazing animals would eat. It is known, however, that animals select grass and clover leaf in preference to stem when grazing[2,3]; these are the more nutritious constituents of the sward, so that by feeding the whole cut from the sward, the nutritive value of the portion stock would eat in the field is underestimated. Thus we need to measure the feeding value of a portion of the sward that we cannot actually analyse, namely, that taken off by the grazing animal. This problem is being investigated at the Grassland Improvement Station.

During May–October 1947, fæces were collected daily from a group of sheep on rotational grazing, and analysed for dry matter, nitrogen and ash.

Fæcal dry matter figures from these sheep indicated that the amount of the daily feed intake was almost independent of the grazing available, but increased steadily with increase of body size. This was at variance with consumption estimated by a mowing machine technique (sampling grazed and protected areas of the sward) which appeared proportional to the amount of feed available[4]. This is because, especially when keep is short, stock obtain much of their feed below the level at which most mowing machines can cut. At times when much growth was available, the mowing machine over-estimated consumption, due to the protected sward growing more rapidly than the grazed sward[5]. The results of these experiments suggest that the usual mowing machine techniques at present used by agronomists may be valueless as methods of measuring with precision the herbage consumed by the grazing animal.

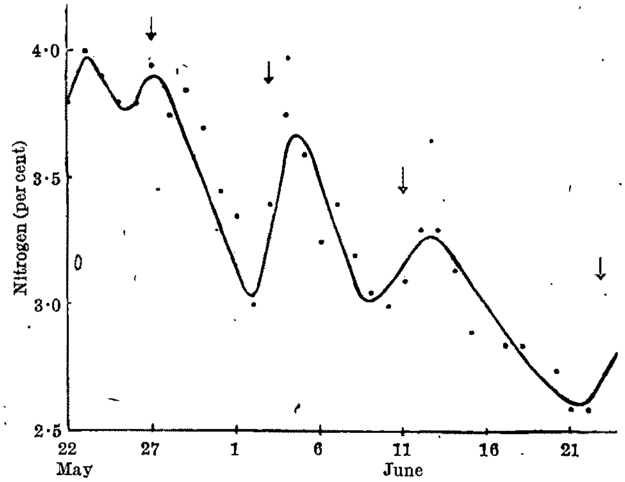
Results of experiments in which mown herbage was fed to sheep in cages[6], together with those from a large number of similar experiments, conducted at Jealott's Hill Research Station[7], have shown the following relation between the nitrogen content of the dry matter of grass fed and of the oven-dried fæces produced:

$$\text{per cent N in feed} = 0\cdot795 \times \text{per cent N in ash-free fæces} + 0\cdot14 \ (t = 17).$$

The grass fed varied from that cut for hay or silage to closely grazed pasture grass; but different constants may apply for other feeds such as lucerne, mountain pasturage, etc.

Considering the process of selective grazing by sheep, it is likely that, day by day, the nitrogen content of their feed from a single plot will decrease, because they are progressively removing the leafiest, nitrogen-rich growth available, and leaving the stemmy part of the growth for subsequent grazing. A move to fresh herbage will make feed of higher nitrogen content available, and the nitrogen in the feed should thus exhibit a periodicity with movement from plot to plot. If, as is suggested by the regression formula given above, the fæcal nitrogen bears a direct relationship to feed nitrogen, the former should show a similar periodicity, with the time-lag of approximately two days normally assumed for the feed to pass through the gut. Analysis of the daily fæcal nitrogen from the grazing sheep has shown this to be so (see accompanying graph) and suggests that in fact the nitrogen content of fodder grazed from one plot does decrease day by day. As the nutritive value of herbage is roughly proportional to its nitrogen content[8], the feeding value of the grazing on this plot decreases daily, and the average percentage starch equivalent depends on the overall intensity of grazing.

Thus the fæcal nitrogen from grazing sheep gives a figure for nitrogen in feed grazed which is probably more accurate than that obtained by analysis of cut herbage. Experiments are now in progress at this Station to find whether analysis of fæces for other constituents (for example, lignin, as suggested by Maynard *et al.*[9], but making due allowance for the factor of selective grazing) together with nitrogen estimations will give a direct measure of the quality of the feed intake. Such analyses could be made on fæces collected from the sward, and need not demand the harnessing of stock. If it is confirmed that the main factor controlling dry matter intake is body-weight, then we should have available a method for measuring the daily intake of nutrients by the grazing animal.



AVERAGE DAILY PERCENTAGE OF N IN ASH-FREE FÆCES FROM TEN SHEEP ON ROTATIONAL GRAZING. ARROWS MARK DAY OF ENTRY OF STOCK ON TO A NEW PADDOCK: THE EFFECT OF INCREASING MATURITY OF HERBAGE DURING THE PERIOD IS SHOWN BY LOWER FÆCAL-N FIGURES ON THE LATER PADDOCKS

I should like to thank Mr. W. S. Ferguson for permission to use figures from the Jealott's Hill experiments and my colleagues at this Station for their considerable help in the present investigations.

Perithecia of Oak Mildew

FORMATION of perithecia of the oak mildew is a rare occurrence in Britain, the only record known to me being that of Robertson and Macfarlane[1], who found one leaf with six perithecia at Bricket Wood, Hertfordshire, on October 6, 1945. It is therefore of some interest to note that a few perithecia were found on leaves of *Quercus robur* at Aberystwyth on October 2, 1947. The identification of the fungus as *Microsphæra alphitoides* Griff. and Maubl. was kindly made by Mr. S. J. Hughes, Imperial Mycological Institute, who compared the Aberystwyth material with a slide of Robertson and Macfarlane's specimen deposited in the Herbarium of the Royal Botanic Gardens, Kew.

RIBOFLAVIN ENHANCEMENT OF RADIOACTIVE PHOSPHATE EXCHANGE BY YEASTS

By Dr. WALTER J. NICKERSON*

AND

Dr. LORIN J. MULLINS†

Carlsberg Laboratorium and Institute for Theoretical Physics, Copenhagen

It has recently been suggested by von Hevesy[1] that processes occurring at the cell surfaces or just inside cell boundaries play an important part in phosphorus metabolism in yeast. We have obtained evidence that we interpret in a similar vein, and suggest the existence of a 'P-complexing factor' at the cell surface.

We have found it possible to increase the radioactive phosphate (P^{32}) exchanged by yeast in the presence of glucose by the addition of trace amounts of riboflavin to the suspending medium. The increases observed range from 20 to 200 per cent over the phosphate exchanged by controls in glucose alone. This effect has been found in two widely different species of yeasts.

The organisms used were *Candida albicans*, a pathogenic non-sporulating yeast, and *Saccharomyces cerevisiæ* (Carlsberg No. 237). Cells were grown in wort or in a medium (*GGY*) consisting of: glucose, 2·0 gm.; glycine, 1·0 gm.; yeast extract ('Difco'), 0·1 gm.; and distilled water, 100 ml., and incubated for 24 hours at 20° C. with constant agitation. The yeast crop was harvested by centrifugation, washed twice with glass-distilled water, and suspended in glass-distilled water to a known density. The P^{32} was usually introduced at this time. Aliquots of the suspension were placed in flasks (with a fritted glass aeration tube leading to the bottom of the flask) in the following medium: yeast suspension, $M/5{,}000$ potassium dihydrogen phosphate, $M/15$ glucose, water or riboflavin (50 µgm./c.c.). The flasks were aerated with washed and filtered compressed air, or with 95 per cent nitrogen with 5 per cent carbon dioxide (passed through a heated copper coil). After the experimental period, the yeast cells were removed by centrifugation, washed twice with glass-distilled water and the yeast cream placed in aluminium dishes adapted for Geiger–Müller counting, and measured automatically[2]. The results obtained in the two experiments reported here are typical of those we have obtained in many other experiments.

Addition of riboflavin (1 µgm./c.c. final concentration) to suspensions of *Saccharomyces cerevisiæ* or *Candida albicans* metabolizing glucose aerobically or anaerobically prompted a marked increase in P^{32} exchange. As shown in Table 1, this addition of riboflavin more than doubled the P^{32} exchanged aerobically by *S. cerevisiæ* with either glucose or sucrose as source of carbohydrate. In the same experiment, 2,4 dinitrophenol in a concentration of 10^{-3} *M* inhibited P^{32} exchange approximately 40 per cent; this is in agreement with the inhibitory action of this substance on phosphate uptake by *S. cerevisiæ* reported by Hotchkiss[3].

If a P-complexing factor is formed at the cell surface, it is possible that, once formed, it might act in the absence of the energy-yielding processes apparently necessary for its formation[4]. An experiment was conducted along these lines wherein *C. albicans* was incubated aerobically at 20° C. in the presence of riboflavin and glucose, then equilibrated at + 4° C. and exposed to P^{32}. Table 2 shows that the starved suspension of the yeast exchanged twice as much P^{32} as the unstarved suspension (both suspensions were prepared from the same culture of yeast). It is also seen that riboflavin prompted a nearly four-fold increase in the exchange of P^{32} by the starved cells, but was without effect on the unstarved yeast. The occurrence of phosphate exchange at a very slow rate by yeast at + 4° C. has been reported by Lindahl *et al.*[5].

TABLE 1. *S. cerevisiæ*, GROWN AEROBICALLY IN *GGY* MEDIUM FOR 24 HR. AT 25° C.
Not starved; exposed aerobically to P^{32} at 25° C., for 5 hr. with treatments as listed (40 mgm. yeast dry wt. per vessel)

Vessel	Treatment	Counts/min./mgm. dry wt. (standard units)
1	glucose + glycine	13·6
2	sucrose + glycine	12·5
3	glucose + glycine + 2,4 dinitrophenol	7·9
4	sucrose + glycine + 2,4 dinitrophenol	7·5
5	glucose + glycine + riboflavin	30·7
6	sucrose + glycine + riboflavin	32·8

TABLE 2. *C. albicans*, GROWN AEROBICALLY IN 'TULAUF' WORT AT 20° C. FOR 26 HR. WITH AGITATION.
Half the suspension not starved (stored at 4° C. for 18 hr.), the other half starved by agitating aerobically in water for 18 hours at 25° C. Both suspensions treated as below for 2½ hr. at 25° C. aerobically with constant agitation (50 mgm. yeast dry wt. per vessel), then placed at − 4° C. for 45 min. P^{32} was then added and flasks held at + 4° C. in presence of P^{32} for 5 hr. Cells separated by centrifugation and washed in the cold

Vessel	Treatment	Counts/min. (standard units)	Counts/min./mgm. dry wt.
	Cells starved		
1	glucose + riboflavin	100	2·2
2	glucose	33·2	0·6
	Not starved		
3	glucose + riboflavin	15·4	0·3
4	glucose	19·5	0·3

The increase in rate of uptake of P^{32} in the residual-phosphorus fraction (presumably metaphosphate[11]) of yeast brought about by cyanide[6] might be considered in the light of the present data on riboflavin in view of the action shown by Pett[7] for the increase in riboflavin synthesis by yeast treated with cyanide. Among the several compounds examined, yeast nucleic acid, uracil, and fructose 1,6 diphosphate proved without detectable effect on phosphorus exchange by *C. albicans* metabolizing glucose aerobically.

Yeasts are well known to be relatively rich in riboflavin, so it is rather surprising to find that added riboflavin exerts such marked effects as we have noted. An average value for the riboflavin content of baker's yeast may be taken from Pett[7] as 20–30 µgm./gm. dry wt., of which 80–90 per cent exists as bound riboflavin. In our experiments usually 30–50 mgm. dry weight of yeast was placed in each flask containing 50 ml.; thus a total of approximately 1 µgm. of riboflavin was introduced into each flask with the yeast. If all this riboflavin were to have been released from the yeast (not possible under our conditions) a concentration of 0·02 µgm. riboflavin per ml. would have resulted. The quantities of riboflavin introduced into each flask as impurities in the sugars and glycine (reagent quality, but not especially purified) are undoubtedly minute. While some species of the genus *Candida* are known[8] to produce sufficient riboflavin on controlled low-iron media to colour the medium, we have never succeeded, using the strains of *Candida albicans* employed here, in obtaining more than very small yields of riboflavin with similar, purified, known-iron media.

* Fellow of the John Simon Guggenheim Memorial Foundation.

† Merck Fellow of the National Research Council.

While it is well known that the presence of external phosphate is not essential for the oxidation and assimilation of glucose by yeast suspensions[9], it is also known that phosphate exchange[4,6] and polymerization (as measured by the increase in basophily[11]) are dependent on the presence of external metabolizable substrate.

In view of the correlation which has been pointed out[3] between the action of 2,4 dinitrophenol on the assimilation of carbon sources by micro-organisms and its action on the uptake or exchange of inorganic phosphate by micro-organisms, it is of interest to compare the action of riboflavin with that of other agents on these two processes. Such a comparison has been made in Table 3 (references noted). It appears there is a decided 1 : 1 correlation between the processes of phosphate uptake and assimilation of carbon by micro-organisms. At the concentrations stated, the agents listed in Table 3 are without effect on the rate of aerobic or anaerobic breakdown of carbon sources. The effect noted[10] for riboflavin on assimilation was observed with the two organisms reported on in this paper. From concomitant investigations[10] on the variation in basophily of yeasts (see Wiame[11]), it is believed that the 1 : 1 correlation between assimilation and phosphate uptake results from the, possibly coupled, simultaneous polymerization by yeasts of inorganic phosphate (to polyphosphates) and of carbon sources (to carbohydrate polymers).

TABLE 3

Substance	Concentration	Assimilation of carbohydrate	Uptake or exchange of inorganic phosphate
2,4 Dinitrophenol	10^{-4} *M*	inhibited[9]	inhibited[3]
Sodium azide	10^{-4} *M*	inhibited[9]	inhibited[3,13]
Gramicidin*	40 μgm./ml.	inhibited[3]	inhibited[3]
Glucose	10^{-3} *M*	a substrate	enhanced[4,6]
Riboflavin	$2 \cdot 5 \times 10^{-6}$ *M*	enhanced[10]	enhanced

* Acting on *Staphylococci*, other agents acting on yeast.

The observation of Malm[12] that phosphate exchange by yeast is sensitive to the *p*H of the medium can be taken as evidence that a surface reaction, easily affected by external *p*H, is involved in phosphate exchange (see Myrbäck and Vasseur[14] for an extended discussion of the considerations underlying this line of reasoning). It is unlikely that phosphate enters the yeast cell in an ionized form, and it seems reasonable that phosphate is brought through the cell barrier by uniting with some 'complexing substance' existing at the cell surface. The compound of this substance with phosphate may then dissociate, or in other manner lose phosphate to the cell (possibly to coenzyme I; see Lindahl *et al.*[5]), and free 'complexing substance' to act again. From our observations we believe that such a role as postulated for the 'complexing substance' may be filled by riboflavin. Combined roles of phosphorus and hydrogen transference for trace-active substances may assume importance in considerations of *in vivo* processes.

We wish to thank Prof. Ø. Winge for facilities at the Carlsberg Laboratorium, Prof. G. Hevesy for most helpful discussion and for reading the manuscript, and Mr. K. Zerahn for his aid in carrying out the activity counts.

FACTORS INVOLVED IN THE DEACTIVATION OF PENICILLIN SOLUTIONS BY RUBBER TUBING

By DR. L. J. BELLAMY and C. H. WATT
Royal Arsenal, Woolwich

COWAN[1] in 1945 demonstrated that aqueous solutions of penicillin could lose up to 50 per cent of their antibiotic activity by simple passage through the rubber tube of a continuous-drip apparatus. These results were confirmed by Huelsbusch, Foter and Gibby[2], who showed that certain samples of both natural and synthetic rubber could inactivate completely the penicillin in solution in twenty-four hours; and also by Hughes[3], who showed that no improvement was obtained by repeated washing of the tubes before use.

At the request of the Medical Research Council through the Ministry of Supply Advisory Service on Rubber, we have been investigating this problem in the hope that we should be able to throw some light on the mechanism of inactivation and on possible methods of improving the quality of rubber supplies. The main technological details will be published elsewhere, and the purpose of this communication is to give a summary of the results relevant to medical practice.

The Effect of Compounding Ingredients and of Vulcanization. Unfortunately, none of the early workers was in a position to supply information on the compounding ingredients other than rubber which were present in the tubes which they tested. These ingredients may well represent quite a large proportion of the total weight, and as some of them are highly active substances it was thought possible that the trouble might be due to one or more of these rather than to the rubber itself. On testing singly a number of such substances, including natural rubber, sulphur, zinc oxide, stearic acid, paraffin wax and a number of accelerators of vulcanization—mercaptobenzthiazole, dibenzthiazyl disulphide, tetramethylthiuram disulphide, zinc diethyldithiocarbamate and diphenylguanidine—no loss in penicillin potency was observed with any of these materials. However, when these ingredients were compounded together in various proportions to give products suitable for rubber tubing and then subjected to vulcanization, the resulting rubber tubes were found to be very active towards penicillin. Thus a rubber tube vulcanized with sulphur and 1·0 per cent of mercaptobenzthiazole reduced the potency of penicillin by 80 per cent in 24 hours at room temperature, and in no case was the loss less than 60 per cent in this period.

Causes of Penicillin Deactivation. It is clear from the above that the active agents in penicillin degradation by rubber must be produced during the complex chemical changes occurring during vulcanization. The major reaction which results in the cross-linking of the rubber molecules with sulphur is unlikely to leave the latter in an active form; but in the process of heating with sulphur, it is not improbable that mercaptan compounds could be produced from any non-rubber components present. This is particularly likely in the case of vulcanization accelerators, many of which decompose during vulcanization with the production of mercaptan compounds. It is known that cysteine is effective in the deactivation of penicillin, and indeed it has been suggested by Cavallito[4] and others that penicillin and other antibiotics inhibit the growth of micro-organisms by reaction with mercaptan compounds within the organism.

In the first instance, therefore, the effect of a reduction in the proportion of accelerators from 1·0 per cent to 0·1 per cent was studied. In each case a substantial corresponding reduction was achieved in the activity of the rubber towards penicillin. Thus in the case of dibenzthiazyl disulphide, the loss of potency of the penicillin was reduced from 80 to 40 per cent, while with a diphenylguanidine-accelerated mix reduction was from 74 to 20 per cent. By the omission of accelerators altogether, a still further reduction was obtained. In some cases the rubber showed no deactivating effect whatever, whereas in others varying effects up to a maximum of 20 per cent were observed.

Confirmation of this finding was obtained by the simple heating of an accelerator—in this case tetramethylthiuram disulphide—to vulcanization temperature for ten minutes. After this treatment the product was found to be highly active towards penicillin, in contrast to its initial inert behaviour. It is therefore clear that accelerators play a major part in the deactivation of penicillin by rubber, and it is clearly desirable that the amounts used should be as small as possible.

The smaller, and variable, activity of vulcanized rubbers containing no accelerator would appear to be due to the reaction of sulphur with impurities rather than with the rubber itself, as otherwise it would be difficult to explain the preparation of some mixes which are entirely inert towards penicillin. Impurities which could react to form mercaptan compounds are often present in small amounts in natural rubber in the form of the so-called 'rubber resins', and some evidence that these may play a part in penicillin deactivation was obtained by testing acetone extracts of vulcanized rubbers prepared without accelerators. Rubber resins and their reaction products with sulphur are largely soluble in this solvent whereas the rubber complex is not, and such extracts were found to be active towards penicillin in those cases in which the vulcanized rubber itself showed activity.

Methods of Minimizing the Degradation of Penicillin. It has already been shown by Yudkin and Pulvertaft[5] that vulcanized rubber is without action upon penicillin in the presence of phosphate buffer, and we have found this to be true even with the most active rubbers which we have been able to prepare. However, where the use of phosphate buffer is impracticable, the potential destructive action of mercaptans will constitute a danger in any form of vulcanized rubber, whether natural or synthetic. In studying possible methods of minimizing this effect, we have obtained some success by the use of a suitable grade of carbon black as an inert filler in the compounding of the rubber tubes. Thus, the incorporation of carbon black in an accelerated mix resulted in the rubber tube showing 27 per cent loss of penicillin potency in 24 hours, whereas an exactly similar rubber tube, containing the same volume proportion of barytes, resulted in a loss of potency of 78 per cent. Comparable results were obtained with a variety of different accelerators. The effect is due presumably to the absorption of active substances and the prevention of their migration to the surface.

The second method examined was the treatment of vulcanized rubber tubes with reagents which are active towards mercaptan groups. This aspect has not yet been studied extensively, but promising results have been obtained by treatment for a few hours with 40 per cent formaldehyde at 38° C., whereby the destructive power for penicillin of a highly active rubber tube was considerably reduced (from 91 to 68 per cent loss of potency in 24 hours). Similar results have been obtained on a variety of different mixes, suggesting that this method of treatment would be worthy of further study, while at the same time lending some support to the view that it is the mercaptan groupings in the vulcanizate which are the active principles concerned in the destruction of penicillin.

Effect of Repeated Sterilization and of Ageing. Small chemical entities such as simple mercaptans are known to migrate to the rubber surface. This suggested a danger that the destructive power of rubber for penicillin would increase with age, and this aspect has also been examined. No alteration in the deactivating power of rubber tubes could be observed by repeated sterilization; but tubes which have been subjected to normal storage for a period of six months were found to show a marked increase in their activity towards penicillin. These tubes were deliberately prepared without the usual antioxidant in order to accelerate any effects due to ageing; but this finding does suggest the desirability of occasional checks upon rubber tubing during its period of use or storage.

Alternative Materials. In view of the obvious difficulties in the preparation of rubber tubes which can be relied upon to be completely without action upon penicillin, we have investigated the effect of a number of alternative materials. Of those which we have studied, polyvinyl chloride, with the plasticizers normally used in its manufacture, and polyethylene, have no action whatever upon penicillin. Polyethylene has the disadvantage that it shows a tendency to kink when used in long lengths, and both materials present difficulties in sterilization as their softening points are below the temperature of the normal steam autoclave. However, polyvinyl chloride can be made in a form resistant to boiling water and is already finding uses in surgery, so that it may prove to be superior to rubber for the purpose of the drip-feed injection of penicillin.

We wish to thank the Chief Scientific Officer, Ministry of Supply, for permission to publish this communication.

LONDON'S TRANSPORT SYSTEM

THE fourteenth annual report, recently issued by the London Passenger Transport Board, makes interesting reading. Since the undertaking is now vested in the British Transport Commission, this is the Board's final report, and it has therefore devoted one section to a review of the way in which it has discharged its functions since July 1933.

Here is an example of the operation of a very large centralized concern run on lines similar, from many points of view, to those which must be adopted in the even larger organisation of nationalized industries or utilities. There can be no doubt that in this instance the arrangement has proved in most ways an outstanding success: the Board has, in the main, achieved its object of providing "a passenger transport service, by rail and road, worthy of London as a great metropolitan city". Few Londoners would deny this: it is not so certain that the inhabitants of some other capital cities would be equally enthusiastic about the transport facilities available to them.

The magnitude of the Board's achievement can better be appreciated by reference to some of the figures contained in the report. The area served covers some 2,000 square miles, with a population in 1933 of 9,358,000. One of the first tasks was to rationalize the unrelated and often wasteful competitive services operated by the many transferred undertakings. During the pre-war years the number of vehicles owned rose from 11,753 to 12,819, and the annual mileage run by them increased from 515 to 573 million miles, providing more than nine million passenger journeys a day in 1933 and ten million in 1939—the usual calculation indicates that if the tickets issued daily were placed end to end they would stretch from London to New York. The receipts from fares rose concurrently from about 27 million pounds to nearly 31 million pounds sterling a year. While this expansion was in progress, the many types of buses and coaches were being replaced by standard designs, the maintenance system was overhauled, new equipment was introduced to increase reliability and efficiency and, most important of all, a vast programme of new works was undertaken in conjunction with the 'main line' railway companies

The outbreak of war caused a great setback to this steady growth. As a result of evacuation, the 'blackout' and bombing, the volume of traffic was so reduced that the system ceased to be self-supporting. But after 1941, traffic again increased and reached a peak of 4,259 million journeys in 1946, totalling 11,479 million passenger miles. The number of journeys made per head of population per year is a measure of the 'travel habit'; this figure rose from just over 100 before the War to nearly 130 in 1946, which certainly indicates no reluctance on the part of the public to travel.

Mention may be made of some of the technical innovations originating with the Board. In 1938 re-designed rolling stock was introduced on the 'underground' railways, the electric motors being installed beneath the floors of the carriages. This eliminated the waste of one car in a seven-car train to house the power plant, and thus gave a 14 per cent increase in carrying capacity. The Board was among the first to recognize the advantages of the oil engine as compared with the petrol engine from the point of view both of performance and of economy in operation and maintenance. It accordingly adopted the oil engine from 1934 onwards as the standard power unit for all new buses and coaches. It was also a pioneer in the large-scale use of the pre-selective gear box and fluid flywheel transmission, which not only ease the work of the driver but also materially increase the comfort of passengers by virtue of the smoother running which they give. Before the War, the trams on many routes were replaced by trolleybuses; but since the War the financial advantage of the trolleybus has decreased to such an extent that further conversion of tramways will be to buses, which are more flexible in operation and offer wider opportunities for co-ordination of all services provided by the use of a single type of road vehicle. Another remarkably successful innovation of the Board was the novel constructional technique employed on the eastern extension of the Central Line.

The first regular passenger service in London was established in 1829, and during the succeeding century development proceeded under a multiplicity of private operators. The extraordinary complexity of the resulting system makes it difficult to offer a fair criticism of the Board's efforts, though it would appear that there is room for immediate improvement in certain directions: the rationalization of routes in the central area and, in particular, the links between the 'main line' railway stations require attention. It is, for example, impossible to get from King's Cross to Victoria station without at least one change, apart from the interstation buses which are so infrequent and circuitous in route as to be virtually useless.

The report concludes with a reference to future prospects and deplores the lack of materials and national restrictions which have prevented a more rapid recovery from the effects of war. It has been argued, however, that the present difficulties are attributable, at least in part, to the policy pursued before the War of scrapping vehicles when the body was worn out, instead of retaining the chassis with a new body and an oil engine; this criticism applies particularly to the 'ST' type of motor-bus. But the Board would probably be the first to admit that errors of judgment have occasionally been made and to acknowledge that the traffic system is still capable of much improvement.

Though the layman may occasionally wonder at some of the oddities of the system—what purpose is served, for example, by the posters informing us that London's transport is at our service when no other means of travel is available, and why does the hand-rail always travel slower than the escalator?—the Board is to be congratulated on furnishing an example of the efficiency which should be attained by all public undertakings.

R. H. MACMILLAN

RADIO RESEARCH IN BRITAIN

A REPORT from the Research Committee of the Institution of Electrical Engineers under the title "British Research in the Radio Field" has been published recently by the Institution*.

While the report includes a general review of the existing facilities for radio research in Great Britain and makes some assessment of the scale of effort involved, it is primarily directed towards considering the means whereby research may be still more actively and effectively pursued and better co-ordinated. The view is expressed that the present volume of radio research is inadequate to maintain, in the face of intensified international competition, a progressive and flourishing radio industry.

Recognizing the difficulty, when describing research in relation to industry, of differentiating sharply between research and development, the report gives a broad general classification under the three headings : (1) basic or fundamental research ; (2) applied research or advanced development ; (3) development and design.

Attention has been concentrated, in the main, on work considered to fall in the first and second categories; but the vital importance to industry of first-class engineering development is also emphasized.

In analysing the distribution of research activity, sub-division is again made under three headings, namely : (*a*) academic research ; (*b*) research by Government establishments, Department of Scientific and Industrial Research and B.B.C. ; (*c*) industrial research.

An interesting comparison is made, in tabular form, of the distribution of the existing capacity and facilities devoted, in these spheres, to various main branches of radio research.

The conclusions and recommendations of the report are the consequences, direct and indirect, of the acceptance as a basic principle that "successful research is more dependent on the qualities, character and inspiration of the research team leaders than on any other factor governing its conduct".

In a paragraph entitled "Research Leaders", it is asserted that "The key to the expansion of research in the radio field, as in all others, lies in the discovery and encouragement of the limited group of men who are competent to act as team leaders and who possess the intellectual and personal qualities which have always proved essential for the successful pioneering of research".

The position of the universities in relation to what may be termed research potential is considered to be a central one on the ground that, not only do the universities, and to a lesser extent the technical colleges, make a very material direct contribution of original research, but also it is through their teaching activities, both undergraduate and postgraduate, that the supply of potential research workers is maintained. Fairly detailed consideration is given to the factors governing the effective pursuit of research and postgraduate study in the universities of Britain, and it is suggested that many of the considerations affecting academic research apply with equal force in relation to industrial research.

In regard to finance, the existing mechanism, whereby official support comes through the University Grants Committee and through the Department of Scientific and Industrial Research, is regarded as satisfactory ; but it is emphasized that an expanded postgraduate programme necessitates increased funds from these sources. It is, however, reiterated that an essential requirement in university research is freedom of action in the development of the research programme.

In relation to the staffing of university research projects, attention is directed to the importance of maintaining, through the work of permanent members of the staff, continuity and integration of effort among postgraduate student members of research teams ; and, in a similar connexion, to the necessity for attracting and retaining in university laboratories adequate numbers of well-qualified laboratory assistants, technicians and craftsmen.

The postgraduate university research worker may vary in age and qualification from the relatively senior holder of a major research fellowship or scholarship to the young graduate of a few months standing. Improved financial provision is regarded as necessary for the important group that returns to the university after two or three years in industry. With regard to the young graduate class, it is recommended that a period of at least six months be spent in industry before taking up academic research.

A considerable part of the report is devoted to the question of the co-ordination of research in the radio field. A primary aim must be the early dissemination of results as widely as possible. Suggestions are made for the improvement of the existing mechanism by the use of an organisation resembling the Central Radio Bureau to collect and circulate information on researches in progress, thereby minimizing the delay which inevitably exists in the publication of completed research through the normal channels. In the field of basic research in the universities, it is considered that co-ordination of effort to a desirable degree can be better achieved by the efficient exchange of current information than by positive co-ordinative action which might take on a restrictive character.

With reference to research in Government establishments, the report welcomes the recent setting up under the ægis of the Department of Scientific and Industrial Research of a Committee on Fundamental Research in Telecommunications, and suggests that a broadening of the terms of reference of this Committee and its establishment on a permanent basis would serve to co-ordinate effectively the main body of research in this sphere. It is further suggested that an effort should be made to maintain something of the co-operation obtained during the War by the Inter-Services Radio Components Research and Development Committee which operated under the Ministry of Supply.

An important example of large-scale technical co-ordination in the telecommunications field is the work of the British Telephone Technical Development Committee, which, under the chairmanship of an assistant engineer-in-chief of the Post Office, achieves the co-operation of the main telephone manufacturing companies in Britain in technical development so that individual research effort is fostered, but also, by the pooling of inventions, a unified development policy for the telecommunications system as a whole is ensured.

Probably the statement of the greatest practical significance, not only in the field of radio communications but also in other subjects, which the document contains is the following: "The Panel have been impressed by the opinion consistently advanced by the University representatives who have attended the meetings that among their graduates those suited to a research career form but a small proportion of the whole; the remainder, while fully competent to absorb and profit by the scientific and technical curriculum, appear to lack those powers of patient and deep-seated inquiry which characterize the natural research worker and lead him to expose new truths".

---

* British Research in the Radio Field : a Report from the Research Committee of the Institution. Pp. 20. (London : Institution of Electrical Engineers, 1947.) 1*s*. Also *J. Inst. Elect. Eng.*, 94, Pt. 1, 502 (Nov. 1947).

Such a conclusion emphasizes the duty of all in industry, research establishments or universities who have the opportunity of discovering real research ability to be vigilant for its occurrence and assiduous in its nurture.

J. GREIG

THE BRITISH COUNCIL

ANNUAL REPORT

THE annual report of the British Council for the year ended March 31, 1947, only became available a short time ago. The report itself is preceded by an introductory re-statement of the general aims, duties and organisation of the Council, which indicates concisely but lucidly the place of the Council in explaining British cultural achievements and the background of social life, and also the broad grounds on which a grant-in-aid of about three million pounds a year is justified. Referring to the widespread demand for teaching the English language created by the War, the report records the Council's decision in principle not to engage in the direct teaching of elementary English, but to assist, in conjunction with the ministry of education of the country concerned, in improving the standard of teaching of the English language. Concluding that too much effort had in the past been concentrated on the intelligentsia and on the capital cities of foreign countries, the Council also made every effort during the year to widen its influence through contacts with workers' educational movements and with study groups in smaller towns, and it is planned to provide a number of short-term bursaries to enable trade unionists, artisans and apprentices to visit Great Britain to meet their fellows and study the conditions of work in factories, etc. At the invitation of the Commonwealth authorities, a centre was established in Australia during the year, an experiment which has been an unqualified success.

During the year, 248 new scholarships, including three senior fellowships, were awarded as compared with 307 in 1945–46, and 190 scholarships were extended. In addition, nearly two hundred private students were assisted by the Council to secure places at British universities; and vacation courses for overseas students were held at St. Andrews, Oxford and Queen Mary College, London, the last being a specialized course on high-voltage engineering. Lecture tours organised numbered 97 in 28 countries, as against 70 in 1945–46. Thirty-seven new brochures, revised editions and reprints were issued during the year, the series generally in most demand in Europe being *British Life and Thought*, *Science in Britain* and *The Arts in Britain*; in the Balkans, the Middle East, Africa and South America, *Britain Advances* and *British People* are more in demand. The Council's work in the field of copyright has now been transferred to the Central Office of Information, but the year was marked by the founding of Council libraries in many European countries and their consolidation in others. Collaboration with the Information Services of the Foreign Office towards pooling resources in joint libraries, functioning both as special reference centres on current British affairs and as Council libraries, is designed to prevent overlapping. Large exchanges of books took place with the U.S.S.R. through the Lenin Library at Moscow, and universities and other centres of Russian studies in Britain have thus received valuable material. In the Colonies, the Council is concerned mainly with assisting the development of library services generally. Two small exhibitions of scientific and medical books were sent to Norway, and an exhibition, with extensive technical and medical sections, toured widely in Switzerland, while one of scientific and technical books was shown in Brussels, Antwerp, Liège, Ghent and Louvain. Some 1,800 periodicals, covering all branches of the humanities, science, medicine and technology, were made available in 1,168 centres in eighty-five countries; and exchanges totalled 3,476, involving 791 foreign and 765 British periodicals, including 77 British Commonwealth publications. Indexes and contents lists for the war years of sixty specialist periodicals were microfilmed and 25 copies of the film distributed to Austria, Belgium, China, Czechoslovakia, Denmark, Finland, France, Greece, Netherlands, Hungary, Italy, Norway, Poland and Yugoslavia, while in Europe 67 universities and specialist libraries in 15 countries were supplied with British periodicals by presentation or exchange.

Scientific workers form a large proportion of British Council visitors to Great Britain and of lecturers sponsored overseas by the Council. In collaboration with the Scientific Instrument Manufacturers' Association, under the auspices of the Academy of Engineering Science and the Swedish Association of Technical Physics, an exhibition of scientific instruments was organised in Stockholm in May–June, 1946. Assistance was given to the expedition planning to survey a large freshwater lake in Venezuela, and arrangements have been made for the exchange of biological specimens between Brazil and various museums and laboratories in Britain. Many countries have used the Science Department for effecting exchanges of material, and the Department has advised on scientific appointments overseas, scientific films and film strips and on the publication of *Science in Britain*. Production of *Science Comment* was suspended in September 1946 as it had become partly absorbed in the modified *Monthly Science News*.

The fourth volume of *British Medical Bulletin*, produced during the year in Spanish and French editions as well, has been placed on a sales basis in countries where currency and other regulations permit, and free distribution is being reduced to a minimum. Medical periodicals received by the Library from other countries, mainly in exchange for the *British Medical Bulletin*, now number more than 650, and all important British medical books as well as many foreign ones are now received for review in the *Bulletin*. The Medical Department also handled an increasing number of inquiries, mainly bibliographical, and supplied many reprints and Photostat copies of articles in response to requests from abroad. Advice was given on questions of technical education and postgraduate training in Britain to 93 overseas studies from thirty countries, ranging over some twenty branches of engineering and science, and advice was also given on numerous agricultural subjects.

PLANT VIRUS DISEASES

FOUR recent papers from the Rothamsted Experimental Station contribute to our knowledge of virus in the pure state and in the infected cell, and also to etiology. E. M. Crook and F. M. L. Sheffield (*Brit. J. Exp. Path.*, **27**, 328; 1946) have examined purified tobacco mosaic virus under the electron microscope. Particles from the slowly sedimenting fraction are almost spherical; but as the sedimentation-rate increases, particle-length increases. Treatment with phosphate and varying conditions of storage further affect the state of aggregation. Potato virus X also has particles of variable length.

N. W. Pirie (Cold Spring Harbor Symposia on Quantitative Biology, **11**, 184) discusses the state of viruses in the infected cell. In a fully documented account, he examines the possibilities that (*a*) the virus particle may form a complex with components of normal tissue, and (*b*) properties of the virus might be altered by the process of isolation. There must also be virus in a 'free' state, and it may be the properties of this phase which have hitherto been assessed. The influence of light intensity on the susceptibility of plants to certain virus diseases has been investigated by F. C. Bawden and F. M. Roberts (*Ann. App. Biol.*, **34**, No. 2, 286; May 1947). Reduction of summer light-intensity to one third increased their susceptibility to infection with tobacco necrosis, tomato bushy stunt, tobacco mosaic and tobacco aucuba mosaic. Shading increased the number of local lesions and the amount of virus in extracted sap and also of systemically infected leaves. Virus from leaves grown in reduced light is also superior for purification studies. The virus of tobacco necrosis has been found by F. C. Bawden and B. Kassanis (*Ann. App. Biol.*, **34**, No. 1, 127; Feb. 1947) to enter plants of *Primula obconica* and to multiply locally; most of the tissues are free from virus. This is in contrast to the systemic infection by most viruses.

I. W. Selman, reporting work at the Cheshunt Experiment Station, has also found (*J. Pom. and Hort. Sci.*, **22**, Nos. 3 and 4, 226; Dec. 1946) that tobacco and yellow mosaic viruses may, under certain conditions, become localized in developing fruits of the tomato for an indefinite period, without the virus infection being completely systemic. The same author has studied the effect of seven different base fertilizer treatments and two levels of watering on resistance of fruiting tomato plants to infection with yellow mosaic (*J. Pom. and Hort. Sci.*, **23**, Nos. 1 and 2, 71; Sept. 1947). Varying the manures had no effect, but over-watering decreased the resistance of plants to systemic invasion by the virus. On the dry border, however, the best result was obtained in one experiment in which only five plants developed systemic infection out of sixteen inoculated. Little critical work has been done on the general question of the growth of a plant in relation to virus infection, but a useful survey of the literature, still by the same author (*ibid.*, *J. Pom. and Hort. Sci.*, **23**, Nos. 1 and 2, 50; Sept. 1947), indicates that studies on these lines may lead to useful control of viruses in practice.

Bulletin 196, Council for Scientific and Industrial Research of Australia (Melbourne, 1946), by J. G. Bald, D. O. Norris and G. A. H. Helson, deals with aphid populations, resistance and tolerance of potato varieties to leaf roll. The aphids *Myzus persicæ* and *Macrosiphum gei* were studied as vectors. There were indications that the stage of development of the potato plant influenced the preferences of both species of aphid. Indeed, the latter species had no preference for diseased Up-to-Date potato plants if leaf-roll had caused severe stunting. Several varieties of potato have been evaluated for their tolerance or susceptibility to leaf roll, but the degree of tolerance is not always reflected in yield.

EDUCATION IN GUATEMALA

IN 1943 the U.S. Office of Education undertook the preparation of a series of basic studies on education in a number of Central and South American countries under the sponsorship of the Interdepartmental Committee on Scientific and Cultural Co-operation. The studies were begun to promote understanding of educational conditions in the American countries and to encourage co-operation in the field of inter-American education. "Education in Guatemala" is based on data gathered by Cameron D. Ebaugh in 1944 and 1945 and supplemented since by documentary study. Published in 1947, exactly a hundred years after Guatemala became a republic, this well-documented account of the state of education in the second largest and most populous of the Central American republics shows how the original method of education by religious indoctrination to limited numbers is now slowly giving way to a system of liberal education for all (Washington, D.C.: Gov. Printing Office).

Instruction by religious orders on organised lines was begun many centuries ago, and a *colegio* to offer education at the secondary school level was founded by a religious order so long ago as 1573. Schools of this type were generally open to the sons of peninsular and, later, of American-born Spaniards, the native Indians seldom being granted admission. In 1676 a university was authorized by royal mandate for the teaching of theology, law and medicine and the conferring of the degrees of bachelor, master, licentiate and doctor. The new institution was given the same scholastic standing as the University of Mexico and in 1875 became the National University of Guatemala; in 1945 it was made autonomous and its name was changed to the Universidad de San Carlos de Guatemala. To-day it is regarded as the most advanced and popular institution of higher learning in Central America.

Education in Guatemala continued largely in the hands of the church until the revolution of 1871. In that year, education was declared the right of all citizens, regardless of caste, creed, age or sex. Many elementary schools and a number of secondary schools were founded by the Government, many of them in former convents. Lay teachers were appointed and curricula devised on lines closely similar to those of Western European Countries. In 1875 the Organic Law of Public Education made public elementary education universal and uniform in organisation, administration and supervision. From that time Guatemala has provided compulsory, free and non-secular instruction at the elementary school level. Because of the lack of school buildings and teachers, however, compulsory education has not been widely enforced. To-day, of the population of 3,407,444, about 70 per cent are still illiterate. As in other Latin American republics, education in Guatemala is highly centralized and administration, organisation and supervision are controlled through the Ministry of Public Education in Guatemala City; the University of San Carlos is alone autonomous.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, June 14

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 3 p.m.—Annual General Meeting.

Physical Society, Low-Temperature Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. C. S. Collins: "Expansion Engines for Helium Liquefaction and Oxygen Production".

Monday, June 14—Saturday, June 19

South-Eastern Union of Scientific Societies (in the Town Hall, Great Yarmouth).—Fifty-second Annual Congress.

Tuesday, June 15

At 8 p.m.—Mrs. Jacquetta Hawkes: "Archæology and the Present" (Presidential Address).

Tuesday, June 15

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. C. E. V. Leser: "Industrial Productivity in England and Scotland".

Wednesday, June 16

Geological Society (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Philip H. Kuenen: "Slumping in the Carboniferous Rocks of Pembrokeshire"; Prof. Alan Wood: "The Structure of the Wall of the Test in the Foraminifera".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Capt. C. E. N. Frankcom: "The Operation of Ocean Weather Ships"; Discussion on "Optical Properties of the Atmosphere" (to be opened by Mr. James Paton).

Wednesday, June 16—Friday, June 18

Illuminating Engineering Society (at the Royal Hall, Harrogate).—Summer Meeting.

Thursday, June 17

Royal Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Discussion on "Analogues of Growth Factors in relation to Antibiotics" (to be opened by Sir Paul Fildes, F.R.S.).

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Jack Spalding: "Impressions of Mining Practice in North America".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. L. S. Bosanquet, Mr. A. E. Ingham, F.R.S., and Prof. E. C. Titchmarsh, F.R.S.: "Some Aspects of the Work of G. H. Hardy".

Institute of Sociology (at Kingsway Hall, Kingsway, London, W.C.2), at 5.30 p.m.—Mr. Leslie Paul: "Personalism and Humanism"; Mr. Gordon Rattray Taylor: "The Nature of an Organic Society".

University of London (in the Senate House, Malet Street, London, W.C.1), at 5.30 p.m.—Prof. H. A. Innis: "The Press—a Neglected Factor in Economic Development since 1900" (Stamp Memorial Lecture).*

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Annual General Meeting; Prof. M. Erfan: "Pulmonary Bilharziasis".

Friday, June 18

Institute of Navigation (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 5.30 p.m.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Technical Authors under the Ministry of Supply for the preparation of technical publications on aircraft and associated equipment used by the Royal Air Force and Royal Navy—The Ministry of Labour and National Service, London Appointments Office, 1–6 Tavistock Square, London, W.C.1, quoting K.U.261 (June 19).

Junior Laboratory Assistant (female) for animal work—The Head of the Nutrition Department, College of the Pharmaceutical Society, 17 Bloomsbury Square, London, W.C.1 (June 19).

Chair of Philosophy in the Natal University College, Pietermaritzburg—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (June 20).

Lecturer in Philosophy—The Registrar, University College, Southampton (June 22).

Gas Light and Coke Company Research Fellowship in Gaseous Fuel and Combustion—The Registrar, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7 (June 24).

Lecturer in Taxonomic Botany—The Secretary, The University, Edmund Street, Birmingham 3 (June 26).

Sewage Research Chemist—The Town Clerk, Town Hall, Bradord (June 26).

Chair of Veterinary Pathology—The Registrar, The University, Liverpool (June 28).

Lecturers in Physical Chemistry, Pure Mathematics, Botany, Agricultural Chemistry, and Agricultural Zoology, at the Gordon Memorial College, Khartoum—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (June 30).

Lecturer and a Junior Lecturer in Mechanical Engineering, and a Lecturer in Pure Mathematics, at the University of Cape Town—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (June 30).

Dewar Research Fellowship tenable in the Davy Faraday Research Laboratory—The General Secretary, Royal Institution, 21 Albemarle Street, London, W.1 (June 30).

Head of the Sheep Section of the Department of Applied Nutrition—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen (June 30).

Senior Entomologist, and Junior Entomologists (2), in the Department of Agriculture and Lands, Government of Southern Rhodesia—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (June 30).

Engineer (Experimental Officer or Senior Experimental Officer), a Physicist (Experimental Officer), and a Physicist (Assistant Experimental Officer), at the Chemical Defence Experimental Establishment, Ministry of Supply, for work in connexion with insecticide research and development—The Secretary, Agricultural Research Council, 6a Dean's Yard, London, S.W.1 (June 30).

Readership in Bacteriology at Guy's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 5).

Research Officer (Cement and Ceramics) in the Division of Industrial Chemistry, Melbourne—The Secretary, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 1524 (July 5).

Lecturer in Surveying to work under the direction of the Professor of Surveying and Photogrammetry—The Secretary, University College, Gower Street, London, W.C.1 (July 23).

Professor and Head of the Department of Aeronautical Engineering, and a Professor and Head of the Department of Internal Combustion Engineering, in the Indian Institute of Science, Bangalore—The High Commissioner for India, India House Aldwych, London, W.C.2 (Bangalore, July 31).

Metallurgists (*a*) to undertake research and development on problems concerning the properties and treatments of steels, (*b*) to investigate problems concerning the applications of steels; Chemists and Assistants (Ref. 'Corrosion') for the development of methods of combating the corrosion of iron and steel; and a Physical Chemist (Ref. 'Steel Making') to study problems in connexion with the physical chemistry of steel-making—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting the appropriate Reference.

Assistant Lecturer in Mathematics—The Registrar, University College, Nottingham.

Laboratory Assistant (male or female) to work in a metallurgical research laboratory—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'Metallurgical Laboratory'.

Lecturer in the Department of Electrical Engineering and Physics—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

Research Chemist—The Director of Research, Research Association of British Flour-Millers, Cereals Research Station, St. Albans.

Senior Technological Chemist, Junior Research Chemists, a Junior Research Physicist, and a Junior Graduate in Physics, Engineering or Chemistry—The Director of Research, British Leather Manufacturers' Research Association, 1–6 Nelson Square, London, S.E.1.

Laboratory Assistant (Grade II) for Physiology Department—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8.

Senior Technician in charge of special Histological Laboratory, National Hospital—The Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1.

Chief Engineer, an Electrical Engineer, and a Chemical Engineer, in the Pakistan Ordnance Department—The Army Technical Liaison Officer, High Commissioner for Pakistan, 16 Fitzhardinge Street, London, W.1.

Geologist on the Geological Survey of the Sudan Government—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Geologist'.

Field Overseer in a Research Unit proceeding to Mauritius to undertake a large-scale mosquito eradication experiment using D.D.T. and B.H.C. insecticides—The Under-Secretary of State, Colonial Office (Research Department), Palace Chambers, Bridge Street London, S.W.1.

EDUCATION AND COLONIAL DEVELOPMENT

A LONG series of reports on almost every aspect of welfare in the British Colonial Empire, quite apart from the quiet but increasing work of the Colonial Research Committee, the Colonial Products Research Committee and other committees concerned with Colonial research in different fields, and more recently of the Colonial Primary Products Committee, have brought many scientific men into close touch with the particular economic, social, scientific and technical problems of these great areas. In the last ten years there have been important general surveys of nutrition, higher education, labour conditions, development and welfare; and also studies in more limited fields such as cocoa control in West Africa, West African oils and oilseeds, the groundnuts scheme in East and Central Africa, the advancement of Africans in industry, and the relation of the game reserves to the slaughter of game, with all of which the man of science is more or less directly concerned. Quite recently, it has been announced that medical specialists from a panel of eighteen will each visit Africa twice in the next six years, and if the experiment, which is being financed by the Nuffield Foundation, is successful, it may be extended to other territories.

Precedent for this unofficial contact is to be found in an earlier visit of university representatives to Nigeria, under the same ægis, or again in Service medicine during the War; scientific workers who have had personal contact or experience with any of these developments may well have been impressed with the way in which Great Britain is facing its responsibilities under the Colonial Development and Welfare Act. Mr. Marquand's recent tour of the East African Colonies is further evidence of the keen interest of the Government in Colonial welfare and development, and of the sincerity of the desire to promote self-government as well as a high standard of living in the British Colonial Empire.

It should not be necessary to do more here than mention the immense potentialities which science itself holds for the promotion of welfare in the Colonies, by the control of or even elimination of disease, the raising of nutrition standards, the improvement of agriculture and production, either by the introduction of more efficient methods or the control of pests of plants or animals, or by extending man's command over natural resources by irrigation and like methods.

Some of the recent advances in such fields promise really spectacular developments in the control or elimination of tsetse fly and other pests, with most valuable results from the point of view of health and economics alike. Nevertheless, even the man of science responsible for such advances can scarcely fail to note the signs of widespread discontent with existing conditions. The disorders which occurred in the Gold Coast early in March and arose out of the serious increase in the cost of living in West Africa, and the evidence of fundamental discontent among the intellectuals in the West Indies which finds violent and extreme expression in the report for 1942–43 of Dr. T. P. Achong, the Mayor of Port-of-Spain, Trinidad, are symptoms of a cynicism and disbelief in British policy and intentions which cannot wisely be disregarded. Inevitably they raise questions about the functioning of democracy among the Colonial peoples, and how best these peoples are to be fitted for self-government.

The contemporary review of British, United States, French and Dutch policy and practice in their Caribbean possessions which Paul Blanshard has written under the title "Democracy and Empire in the Caribbean"* is of interest from that point of view. The picture of the British West Indies as seen through American eyes is instructive, if sometimes a little crude, unimaginative and intolerant; but the comparative appreciation of the practice of the four Colonial Governments is fairer than some of his criticism, and beyond that he displays plainly the fundamental aspects of the situation in the Caribbean. This book makes very clear the background against which the Colonial research committees have to work, and in particular the limits which economic, social and political factors set to the work of the Caribbean Research Council.

Many will think that Mr. Blanshard takes too pessimistic a view of the prospects of regionalism and of the future of the Caribbean Commission; some of his criticism leads naturally to such pessimism. None the less, his forecast of the future may well be near the mark, for in it he seems to shed some of his prejudices. He believes that for most of the Caribbean colonies, independence is undesirable and undesired by the people themselves; but he urges that the first step in political progress is to make all legislatives genuinely democratic, and that next the governors should be elected by the people or their elected representatives. He admits, indeed, that in some areas the people are obviously unready for this step, and that when it is taken safeguards will be required for the standards of the Civil Service; clearly his criticism of the present system is not to be taken entirely at its face value.

Next, the colonies of the Caribbean should be fitted into a democratic regional agency with power to co-ordinate and develop the economic life of the area, and serve as a link between the region and world organisation. He would place all these colonies under the Trusteeship Council of the United Nations, giving the Council full power to investigate and report upon all aspects of Colonial administration. Here again he admits that his proposition has no immediate hope of realization, and he further recognizes that all his political proposals demand universal, free and compulsory education for a generation as preliminary preparation for self-government.

In the economic sphere, he says little about the question of nutrition and raising the standard of living, though he recognizes a trend in the area towards increasing social control of economic life and the need to maintain the large-scale plantation system, regardless of the type of land ownership, because of the greater productive efficiency of large operating units. He has little to say about the contribution of science to the social welfare or economic progress of the area, though, surprisingly in view of much of his criticism, he concludes on the note that the Caribbean peoples will remain loyal to the Western democracies, provided that those democracies be worthy of their allegiance.

Mr. Blanshard's book should certainly dispel any complacency with which British rule in the West Indies is regarded, or even the operation of the Colonial Development and Welfare Act. There is, however, a wealth of material against which the objectiveness of his criticism can be tested, and it is to be hoped that his book will stimulate at least some scientific workers to make that effort. What stands out most clearly is the need for much closer and objective study of the working of democratic institutions among the Colonial peoples, and the means by which the idea of true local self-government may best be furthered in terms of the economic, social and cultural as well as political welfare of those peoples.

Mr. Blanshard, although at times excessively caustic in his comments upon governors in the Colonial systems, is not so obsessed with his dislike of that system as to fail to recognize that the strongest indictment of the Colonial Powers in the Caribbean is that for a hundred years after emancipation they did so little to prepare the people for self-government, and that the Caribbean peoples were not given a fair chance to learn democracy by practice. Nevertheless, his survey makes little constructive contribution as to the way in which that problem of education is to be tackled, and for all its merits as a comparative study of different systems and as a guide to the trend of local opinion—in which last a bibliography and some notes and comments on Press articles are useful further aids—his book of three hundred and seventy pages, so far as education is concerned, falls far short of the forty-page report on "Education for Citizenship in Africa" which has come from the Colonial Office Advisory Committee on Education in the Colonies (London: H.M.S.O. Colonial No. 216, 1948. Pp. 40. 9*d.* net). It might be objected that the sub-committee responsible for the report should have included a representative of the Colonial administrators on whom will fall the main burden of providing the appropriate political and economic organisation, and some Africans whose presence might have added to its authority. No such additional representation could well have improved on its statement of general principles, or increased its consciousness of the necessity of preparing not merely Africans but also other Colonial peoples for self-government, and affording them the opportunity for its practice.

Under its terms of reference, the sub-committee was to study the technique needed to prepare people for responsibility, and examine generally the problem of building up a sense of public responsibility, tolerance and objectivity in discussion and practice, and an appreciation of political institutions, their evolution and progress. It was decided, however, to prepare a report which, though taking Colonies outside Africa into consideration so far as possible, should frankly apply principally to Africa, where its members had principally gained their Colonial experience. Speaking of the title of the report, the Committee emphasizes that there is no true education which is not education for citizenship, and that education which does not produce good citizens has not justified its claim to be called education at all. It is in this spirit that the Committee faces the central purpose of British Colonial administration, which has been described by successive Secretaries of State for the Colonies in similar terms, namely, to develop the Colonies and all their resources so as to enable their peoples speedily and substantially to improve their natural resources and, as soon as may be, to attain responsible self-government.

---

* Democracy and Empire in the Caribbean: a Contemporary Review. By Paul Blanshard. Pp. xi+379. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1947.) 25*s.* net.

Self-government, however, is a much heavier responsibility in the twentieth century than in the eighteenth, and in pointing out that education must aim at fulfilling the special needs created by social and political changes and that with the great variations in culture, in social and economic conditions in the Colonies the path to self-government can scarcely be the same for all, the Committee affirms its belief in the soundness of the principle, which has guided British Colonial education policy in the past, that education to be effective must be based partly at least on local conditions. Not only must it take account of cultural differences; it must equally seek to present to the Colonial peoples Western civilization at its best side. The Western world should place its political experience of democracy and its conception of democratic government at the disposal of the Colonial peoples without any reserve. It will be for them to make what use they think fit of this experience. We must remember that democracy is not merely a matter of political institutions but of the spirit in which they are worked; democracy must arise from within, though it may be helped or hindered from without, and it can only be judged by being seen in action.

It is in dealing with the difficulties that exist in the path of the Colonial peoples who are endeavouring to advance towards full citizenship of the modern world that the report is so much more realistic than Mr. Blanshard's book. There is no less sympathy with, or understanding of, the aspirations of nationalism; but the disintegrating influence of Western civilization is more fully appreciated. The prerequisites of democracy are clearly stated: a profound belief in the value of the individual, and with it a general feeling of confidence in one's fellow citizens; the intellectual equipment—not merely informed minds, but minds capable of straight thinking and not to be deceived by the demagogue; and a political and economic organisation which permits such spiritual and intellectual qualities to flourish.

Much of the report is occupied by detailed recommendations, throughout which runs one main principle already adumbrated: you cannot educate people for citizenship unless you give them the chance of exercising their citizenship. For this reason the Committee urges that every opportunity should be taken of entering into full and frank discussion with the Colonial peoples while policy is still only half-formed and even if no formal organisation exists for such discussions. The importance is emphasized of bringing together around the council table the young educated men and the traditional elders; and that any tendency to restrict discussion on the plea that the people are not yet able to understand the questions involved is shirking the task of education for citizenship.

The report urges in conclusion that the task is too great to be left to one section only of the Government organisation, or of the European or educated Colonial public. The task is so large and urgent that the help of everyone will be needed, and in one section of the detailed recommendations, dealing with the teaching of science, the Committee shows how the man of science can help. It suggests the study of science from the historical point of view, with a background of its social implications and an indication of the indirect contribution to education for citizenship which training in science in this way can make. No constructive educational policy can ignore the dangers of producing a class of men of mainly academic training larger than can find a useful place in the body politic, and of neglecting the improvement of craftsmanship. One sound reason for welcoming such developments as the groundnuts scheme in East Africa is the increased outlet it might afford for African craftsmen and technicians; and for that reason alone the unexpected difficulties and greater cost of the scheme should not be allowed to exert undue influence. Similarly, while we may welcome wholeheartedly the recent recommendation for an institution of full university standing in Malaya, neither there nor in the West Indies nor in Africa should it be forgotten that with economic and industrial and educational development must go a careful study of the social-psychological factors which underly the rising tide of nationalism and have provoked the disorders on the Gold Coast and elsewhere. The full inquiry already promised into the Gold Coast riots, for example, should establish the facts; but something more is needed. Fundamental research into the real causes of Colonial discontents is a matter of the greatest urgency, not merely to point the way to appropriate remedial measures, but also to assist in the adjustment of our own attitude to the Colonial peoples. Collaboration with other peoples is imperative not only for the development and welfare of those peoples, but also to enable them to make that contribution to the welfare of mankind at which Mr. Bevin hinted in a memorable speech early this year; and collaboration involves mutual understanding and trust. The proposal for the establishment of a University of Malaya is much more than a further token of our goodwill and of our determination to build a noble structure of higher education in the Colonies. It is equally important as one more step towards the provision of institutions where fundamental research can be prosecuted, and where the Colonial peoples may learn the technique of research in many fields where it is so urgently required. In that way and in co-operation with their Western teachers they may make their own distinctive contribution in advancing knowledge, and also gain the vision and wisdom which will increasingly fit them for the searching responsibilities of full self-government.

APPROACHES TO SOCIOLOGY

From Max Weber

Essays in Sociology, translated, edited and with an Introduction by H. H. Gerth and C. Wright Mills. (International Library of Sociology and Social Reconstruction.) Pp. xi + 490. (London: Kegan Paul and Co., Ltd., 1947.) 21*s.* net.

The Analysis of Political Behaviour

An Empirical Approach. By Harold D. Lasswell. (International Library of Sociology and Social Reconstruction.) Pp. ix + 309. (London: Kegan Paul and Co., Ltd., 1948.) 21*s.* net.

MAX WEBER was no believer in mystical doctrines of national genius, but he did believe that given societies had their own way of noticing, defining, and solving problems. There was, for example, a British way of approaching physics that differed from the Continental way. This truth is admirably illustrated by these two important new volumes in the "International Library of Sociology". It is not a simple contrast between the German academic temperament and training and the American. Max Weber was, in many ways, *anima naturaliter Americana*. But as a German professor and a German citizen deeply and justly concerned for the present and future of his country, he was bound to deal with different problems than those which rightly concern and interest Prof. Lasswell; and if the publication of these books had no other justification, it would have this, that the two books illustrate this difference of approach and of method.

Max Weber's fame in Britain is mainly due to his "Protestant Ethic", and however much that famous essay may be criticized, it did illustrate an important truth, that there is not, in the nineteenth-century sense of the word, a political or economic 'religion of all sensible men' that has only to be set out to be accepted. The uniqueness of the European economic and scientific achievement was bound up in some form with the 'configuration of institutions'—and of ideas caused by and causing the configuration. It has reasonably been objected that Max Weber simplified his problems, produced too neat contrasts; but he did sow an idea that has had its fruitful crop.

In this collection, naturally, attention has mainly been directed to those parts of Weber's very varied contributions to our knowledge of society that have not been already translated, and it might be said that the reader coming to Max Weber for the first time might do well to read Prof. Talcott Parsons' introduction to "The Theory of Social and Economic Organization" (that is, the recent translation of Part I of "Wirtschaft und Gesellschaft"). But the choice of themes has been judicious and it gives the flavour as well as the weight of Weber's work. For this reason it is probably worth having the essays on the Chinese *literati* and the Indian caste system, though they are not novel or particularly enlightening to-day.

The main themes of these selections are centred around power in its various forms, economic, political and intellectual, and around organisations of power—feudalism, bureaucracy, churches, universities. Contemplating the problems of power, Weber was repelled by two fashionable German doctrines, simple Marxism and the great national superstition of belief in the expert. Marxism repelled him much less than the ignorant and dangerous complacency of the German officers, officials, professors. Professing to be an aristocracy, they were complacent and, in the field of general politics, highly incompetent *dilettanti*. Weber was fascinated by America, to which he went with a far more open mind than did most Europeans, above all than did most Germans. He held the view, not as a paradox but as a saving truth—if only he could get it accepted—that Tammany Hall was a more valuable political institution than the German bureaucracy with its flippant monarchical top-structure and its pedantic, complacent and deeply maladjusted professorial allies and apologists. Few political essays written in a time of crisis read better, a generation later, than "Politics as a Vocation", a sermon in the Munich that knew Kurt Eisner and was about to house Hitler; and the prophecy of the coming of the "charismatic leader" is almost awe-inspiring. Of almost equal interest, though calling for less remarkable powers, is the essay on German universities; and the two taken together explain a great deal about the fate of the Weimar Republic—and the present problems of German rehabilitation.

When we turn to Prof. Lasswell we are conscious of a drier light and a cooler ambition. Prof. Lasswell takes for granted the democratic premise that the object of a democratic society is "the realization of human dignity in a commonwealth of mutual deference". That society will be more easily attained and maintained if we think hard about what we are aiming at and import as much controllable knowledge into our policy-making as is humanly possible. There are many dangers which face American (or any other) democratic society; but Prof. Lasswell is mainly concerned with two. One is the degree to which a society abolishes or encourages "skill blockades", impedes the ability of the individual to contribute to society and to acquire the resources to contribute. All existing societies impede, unnecessarily, such contributions, by financial, racial, dogmatic, political barriers; all are obstacles to the "open society" (to borrow Prof. Popper's useful term). The most interesting example of Prof. Lasswell's analysis of such problems is to be found in his proposals for the reform of American legal education. In no free country do lawyers play so great a part as they do in America. It is not only that constitutional law gives the courts and so the lawyers an importance to which there is no European parallel, but (possibly for reasons that would have interested Max Weber) the lawyer has had his prestige and field of functions greatly extended. So the curriculum of the great law schools is of the utmost importance and the criticism of it made here is very enlightening. Critics of the preliminary training of British Civil Servants or advocates of increasing the number of administrators who are trained scientists might well ponder, in an English context, Prof. Lasswell's questions and answers.

Both these books are so timely that it is perhaps unkind to end on a note of criticism. The translators of Max Weber have excellent principles and nothing could make him easy to read. But too often he has been translated into a language that is almost as near German as it is English or American, and this holds up the reader and may put him off. D. W. BROGAN

SOLAR AND TERRESTRIAL RELATIONSHIPS

Sunspots in Action

By Dr. Harlan True Stetson. Pp. xiv+252. (New York: Ronald Press Co., 1947.) 3.50 dollars.

THE time is surely ripe for the appearance of an authoritative popular work dealing with the fascinating topic of sun–earth relationships. If Dr. Stetson's book fails to qualify for acceptance in this category, it may well be because he devotes too much space to what is uncertain and speculative, while giving too little attention to those relationships which are clear and unassailable.

The amplitude of the 'daily variations' in the terrestrial magnetic elements has shown a close correspondence with the Zurich sunspot numbers over more than a century. Both variables are capable of precise measurement, and an examination of Fig. 13 in Dr. Stetson's book will show that the correlation between them is of the closest kind. At rare intervals also there occur very violent fluctuations of the magnetic elements, known as 'magnetic storms'. Maunder, of Greenwich, showed, more than forty years ago, that each 'great' magnetic storm coincided in time with the passage of a large sunspot across the sun's central meridian. More precisely, the storm began about thirty hours, on the average, after the central meridian passage of the sunspot. The converse, however, was not true, that the central meridian passage of every large sunspot was followed by a magnetic storm. It remained uncertain whether the corpuscular stream responsible for the storm was emitted continuously from the sunspot region, confined, perhaps, to a narrow radial beam which sometimes missed the earth altogether, or was emitted only intermittently, some of the larger spots being relatively inactive in this respect.

Atmospheric ionization must be attributed in a general way to the action of solar ultra-violet light, with perhaps a small contribution from meteors, and it will therefore reflect in its changes the progression of the spot-cycle. However, with the development of the spectrohelioscope by Hale (1926), chromospheric flares came to be recognized as sudden, short-lived emissions of monochromatic radiation (including enhanced ultra-violet) and having their origin in the vicinity of active sunspot regions. Spectrohelioscope observers, co-operating under the ægis of the International Astronomical Union, rapidly accumulated a large body of facts. These results were discussed by H. W. Newton in an important series of papers, in which he established that each intense (3+) flare was followed by a remarkable train of events. The radiation emitted by the flare is both wave and corpuscular. Simultaneously, with the visual observation of the flare by light of the hydrogen α line, a burst of ultra-violet light reaches the ionosphere, giving rise to: (*a*) the magnetic 'crochet' effect, (*b*) the low-level (*D*-layer) ionization which causes the fade-out for short-wave radio transmissions (Dellinger effect) along sunlit channels of communication. Some twenty-six hours later, with the arrival of the charged corpuscular stream (emitted at the time and place of the flare), the 'sudden commencement' marks the onset of the magnetic storm, with its accompanying radio and visible (auroral) effects. The discussion of the locations on the sun's disk of intense flares preceding magnetic storms makes it clear that the corpuscular stream is confined to a radial beam of semi-vertical angle about 40°.

Thus Maunder's statistical relationship between magnetic storms and the central meridian passages of large sunspots is found to be, in reality, a one-to-one correspondence between storms and intense flares associated with the sunspots near the times of their meridian passages. None of this is made at all clear by Dr. Stetson. Indeed, we find no reference, either in the text or in the bibliography, to the work of Newton, Waldmeier and others on flares, and Maunder is referred to, but in quite a different connexion, as Professor (*sic*) Maunder and in the index as A. S. D. Maunder (which was Mrs. Maunder). The author seems to regard sunspots as the primary phenomenon in all his relationships, whereas most solar physicists would now consider the spots as no more than the visible accompaniments of the much more extensive 'active regions' which are manifest through the occurrence of flares, active prominences, coronal excitations, bursts of radio-noise and in other ways. In Fig. 30 we find an unusual version of Maunder's 'butterfly' diagram, intended to illustrate Spoerer's law of the progression in latitude of sunspots with the eleven-year cycle. In the absence of a description of how the diagram was plotted, the reader will naturally conclude that there are *three* distinct belts of spots, instead of only one, on each side of the solar equator, and that each progresses independently towards lower latitudes as the cycle proceeds.

In the first six chapters the reader will enjoy very entertaining and lucid accounts of such subjects as the origin of solar energy, the measurement of the solar 'constant', the conditions in the ionosphere and the means by which radio-waves are propagated round the globe. There is also an admirable description of ionospheric sounding by the method of 'critical frequencies'. It is clear that Dr. Stetson is much more at home on the radio side.

In later sections the author summarizes much that has been written in an endeavour to relate the sunspot cycle to such matters as the growth of trees, world weather, economic cycles and human health, and he makes a plea for the further study of what he calls 'cosmecology', that is, the relationship of the earth to its cosmic environment. It is in these spheres, where we are no longer dealing with variables capable of accurate measurement, that knowledge becomes vague and a prey to opinion.

M. A. ELLISON

FISHERMAN AND NATURE LOVER

A River Never Sleeps

By Roderick Haig-Brown. Pp. 320. (London and Glasgow: Wm. Collins, Sons and Co., Ltd., 1948.) 12*s*. 6*d*. net.

NO writer has written so vividly of fishing since Lord Grey of Fallodon. Roderick Haig-Brown's book has the rare combination of good prose written by a man who is a master of the subject on which he writes.

The book is divided into twelve chapters, under the twelve months of the year, and the author describes fishing experiences, both in Great Britain and in British Columbia, where he now lives. He is a skilled fisherman, but he is modest in describing his exploits. He is able to write with so great a vividness that the scene at once is brought before the mind of the reader. Take his description of the death of the Pacific salmon after spawning. This is one of the most strange, even inexplicable, tragedies in the world of Nature. Of the millions of Pacific salmon which enter the rivers to spawn, not one returns to the sea. It is strange, as the author says, that they should all die, not one escape, and strangest of all that the change should be from fullest life to death, with no intermission of growing weakness between. The act of spawning, both in the female and the male, soon brings death, grim and inevitable. The following description (p. 276) of the drama may give an idea of the author's clear and arresting prose: "The will to live continues after spawning. It would be reasonable to expect a resignation to the inevitable, but there is none. A spawned-out fish, almost dead, will turn away from danger in a surge of fear-built strength. I once watched two spawned-out, huge fish, in the shallow water of a long, broken rapid. They showed at first just over the lip of the pool above, dorsal and caudal fins breaking as the current forced them down. They drifted a little way, weakly and awkwardly and then, as though suddenly afraid of death, one threshed its way with furious strength for ten or a dozen yards upstream. The other followed instantly, and for a while they held, side by side again, weaving back and forth until the current caught their sides and swept them down. This happened many times; and each time they were swept down they fought back again, keeping always together but never winning back quite to the place they had left. They swung over at last into an eddy on the far side and seemed to rest there, because I could not see them again. There was a painful sadness in watching, a bleakness in the struggle against death that could gain nothing. . . . It is strange that they should all die, that life should go out with the spawn; for it does go out with the spawn. Age has little to do with it, for even the grilse die."

Yet, as the author points out, not all Atlantic salmon die after spawning. Many of these salmon return to the sea, though a few return again to spawn in the rivers. The restoration of the Atlantic salmon must come within, for there is little feeding in the rivers, yet a 'well-mended kelt' caught in the Scottish rivers in April is sometimes at first glance hard to distinguish from a clean fish. Many of these spawned fish apparently return to the sea in safety, yet very, very few come back to the river to spawn a second time. It is now known that the main feeding area of salmon is in the deep Atlantic. Can it be that the kelts recover their strength, and remain in the deep ocean for the rest of their lives ? Otherwise, what happens to the well-mended kelt ?

On one occasion when Mr. Haig-Brown was fishing, he watched a bear fishing on the farther side of the river; but the bear was less successful than the human angler (who had caught two salmon) and had no luck at all ("He looked sad and lonely and defeated, the more so because he was so big").

In all the author's writing is sympathy and understanding for the wild creatures. I have likened his writing to that of Lord Grey, yet there is one difference—he writes little of the birds of the rivers he has fished.

His story of his black Labrador reminded me of our faithful collie Dileas. She was as enthusiastic in salmon fishing as I was, and when a salmon jumped far out in a pool she would run with great excitement and stand opposite where the fish had showed, but she did not look from the splash to the rod's top, like the Labrador in this book.

Hear (p. 253) what the author has to say about this remarkable dog:

"When we came to the river he would stand beside me if the water was shallow, or sit on the bank as near to my wading as he could get, ears cocked, legs trembling a little. His eyes would follow the line of every cast, watching the drift of a dry fly or the sweep of a wet fly as closely as I did. If I moved my rod point sharply, he would press forward, his whole body trembling; if a fish jumped free in the river he would look from the splash to the rod top and back again in puzzled surprise to the splash. Whenever I hooked a fish he whined a little and followed every move of the fight until the fish was beaten and I sent him in to retrieve, which he always did faultlessly, bringing the fish to hand without a mark on it to show how he had held anything so awkward and slippery. He retrieved hundreds of fish for me, fish of all weights up to ten or twelve pounds, and I never lost one through him."

One of the charms of this outstanding book is that it must appeal not only to the fisherman, but also to the lover of wild Nature—and indeed to anyone who has an eye for good writing. SETON GORDON

MICROWAVE ELECTRONIC VALVES

Klystrons and Microwave Triodes

By Asst. Prof. Donald R. Hamilton, Assoc. Prof. Julian K. Knipp and J. B. Horner Kuper. (Massachusetts Institute of Technology, Radiation Laboratory Series, Vol. 7.) Pp. xiv+533. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 45*s*.

DURING the last year of its existence under the supervision of the National Defense Research Committee, prior to July 1946, the staff of the Radiation Laboratory at the Massachusetts Institute of Technology was chiefly occupied with the writing of twenty-eight large volumes on the scientific principles and techniques of radar: a task which has become known as the "five-foot shelf". The work described in these volumes is, as Prof. Du Bridge says in a foreword, the collective result of work done at many laboratories, Army, Navy, and industrial, both in the United States, in Britain, Canada, and other Dominions. I cannot recall that a task of this magnitude has ever before been undertaken by the staff of a single scientific laboratory. In assessing the achievement, one has to remember that the writing was done at a time when it must have been difficult to show a proper historical sense in relation to the share of other countries and laboratories; the personal and even the national share in any one discovery had often been lost in the tremendous urge to make of radar a decisive weapon of war. Many volumes of the series are still to appear; but all were written before the spate of post-war scientific papers had set in. Some effects of this no doubt deliberate editorial policy can be seen in the volume under review: the index contains very few references to individuals; such references are confined almost entirely to textual footnotes. In a book which devotes many of its pages to the klystron, one is surprised not to find the name Varian in the index. As is usual, scientific progress outstrips the speed of publishing, and reference to the important work at Oxford on the travelling-wave tube is confined to the preface.

Volume 7 deals with the basic principles underlying the operation of klystrons and planar-grid valves (such as the lighthouse and disk-seal types) as oscillators and amplifiers, with special emphasis on fundamental principles rather than descriptive or constructional details. The first four chapters discuss the fundamentals of valve types and function, electronic and circuit phenomena at high-frequencies. Chapters 5–8 are concerned with planar space-charge valves as amplifiers and oscillators and the pulse operation of microwave triodes.

More than half the book (Chapters 9–18) deals with klystrons, and the treatment is comprehensive. There are chapters on velocity modulation and klystron bunching, amplifier klystrons; frequency multiplier and reflex klystron oscillators, load effects, and hysteresis; noise in reflex klystrons; modulation, and practical reflex klystrons.

Chapter 15 on load effects in reflex klystrons is good, and of quite general usefulness apart from its context; the long-line phenomena are discussed in quite a clear way. The British reader, perhaps inevitably, takes exception to occasional Americanisms; this text is singularly free from such defects or jargon. The use of the term 'electronic equivalent' in the sentence "probably the best known type of the external cavity is the 707B or its electronic equivalent, the 2K28" on page 495 is certainly, however, open to objection.

Those who have some acquaintance with the subject-matter of this volume will already be aware that it cannot be presented without a good deal of mathematical background. The volume is well suited to those wishing to make use of klystrons and microwave triodes in a particular field of research. It is not suited, as a whole, to the undergraduate, unless he is fortunate in having an expert to guide him. There are, however, chapters of special value in this connexion; readers whose interest is of a general character would do well to study the relevant portions of the introductory volume to the series, edited by L. N. Ridenour. J. T. Randall

INTERNAL SECRETION

Textbook of Endocrinology

By Prof. Hans Selye. Pp. xxxii+914. (Montreal: University of Montreal, 1947.) 10.25 dollars.

Prof. Selye's "Textbook of Endocrinology" is probably the most complete account of the subject which has yet appeared, at any rate within the compass of a single volume. It is, however, only a miniature of the much larger "Encyclopædia of Endocrinology" which the author is bringing out in many volumes, six of which have so far been published, but which, it is hoped, will ultimately give a critical survey and a complete guide to the entire endocrinological literature. The present volume begins with an interesting preface by Prof. Houssay, of Buenos Aires, who points out how far we are from the theories which prevailed between 1880 and 1900 and which attributed to the internal secretions the role of neutralizing and destroying the toxic substances arising in intermediate metabolism. Long before that time, however, Berthold definitely promulgated the idea that an organ may exert its influence upon the bodily characters or upon other organs by means of chemical substances secreted internally into the circulating blood. This was in 1849, when he published his experiments upon testicular transplantation in fowls. His work was for many years lost sight of; but his results have been completely confirmed. In the meantime, Claude Bernard employed the term 'internal secretion' to describe the glycogenic function of the liver, because this gland stores up carbohydrate as glycogen and secretes it into the blood as sugar. Brown-Séquard's claims, made in 1889, to have rejuvenated himself as a consequence of injections of testicular extract attracted a great deal of attention, and although they did not stand the test of a later examination and repetition, nevertheless are usually regarded as marking the beginning of the modern science of endocrinology. The term 'internal secretion' is now usually restricted to substances which, after being carried in the blood-stream, promote the secretion of particular glands or the growth of particular tissues on which they have a specific action. Such chemical excitants were named 'hormones' by Starling in 1905. Prof. Selye does well to remind us of the beginnings of a science which in recent years has developed into such a large and important branch of physiology.

In the succeeding chapter, the author describes the chemistry and pharmacology of the steroids. This is a group which contains four sub-divisions of substances of similar chemical constitution and hormonal action, namely, the œstrogens, the androgens, the progesterone-like bodies and the compounds with a 'cortin-like' action. It is interesting to note that any one of these substances may produce not only its own characteristic effects but also some of the effects of those of the other three groups. The author next deals in alphabetical order with all the organs of internal secretion, and the account of these is followed by a chapter on the hormones or hormone-like substances produced by simple endo-exocrine and non-glandular organs, and a final chapter on functional correlations. The pathology of the organs is very fully described, and this is a feature of the book. There are numbers of illustrations and many of these show the effects of endocrine diseases.

In a book of this size, it was inevitable that there should be mistakes, as the author himself remarks; but it is unfortunate for science when an important text-book contains misleading statements about the reproductive processes of common domestic animals, and such as any practical breeder knows to be absurd; for example, the statement that the so-called pre-œstrous bleeding in the dog occurs at the mid-interval between two œstrous periods. Moreover, monœstrous mammals are those with one œstrus in the sexual season, not those with one cycle per annum, as the book states; and again, the diœstrum is not a phase of complete sexual rest but an abbreviated pseudo-pregnancy. There are other similar mistakes; but they must not be regarded as detracting seriously from the value of the work as a whole. In my opinion the book would benefit by giving the references to the more important papers that are quoted, for this is only occasionally done.

F. H. A. Marshall

A TECHNIQUE FOR MECHANICAL VIBRATION PROBLEMS

Mechanical Admittances and their Applications to Oscillation Problems

By Prof. W. J. Duncan. (Ministry of Supply: Aeronautical Research Council, Reports and Memoranda, No. 2000.) Pp. 128. (London: H.M. Stationery Office, 1947.) 22*s*. 6*d*. net.

IN the days when electrical engineering was emerging from physics and when alternating current circuit theory was in its infancy, progress was greatly helped by the fortunate circumstance that the equations to which the new theory led were formally similar to those already encountered in mechanics. Thus Maxwell, in his treatise, devotes a chapter to the dynamical principles and equations of Lagrange and Hamilton, and is at pains to stress the fact that the circuit equations fall within their scope. As it grew, electric circuit theory elaborated concepts, developed techniques, and invented a nomenclature, appropriate to the problems encountered and to their growing complexity. More recently, problems in mechanical vibrations, of increasing complexity, have presented themselves, notably in aeroplane design, and circuit theory has been able to repay with interest the debt it has for so long owed.

The word 'admittance' in the title of this monograph is borrowed from circuit theory, where it signifies, for any branch, relative to a pair of terminals, the ratio of current in the branch to E.M.F. across the terminals. The most obvious analogue of electric current is mechanical *velocity*, but since the interest in mechanical problems is more often focused on *displacement*, the liberty has been taken of altering the significance and of defining 'mechanical admittance' as a ratio of displacement to force—with 'displacement' and 'force' used as in the language of generalized co-ordinates. More immediately descriptive terms would have been 'dynamic flexibility', or a 'dynamic influence coefficient'—expressing the harmonically varying response to a harmonically varying unit stimulus.

The power of the 'admittance' method lies in the ability it confers of expressing rapidly the displacements at chosen key points of a system in terms of internal and external forces acting on the system or upon a sub-system. Eliminating internal forces from the set of equations so formulated leads to either (i) the frequency equations in the absence of external forces, or (ii) equations for the chosen (generalized) co-ordinates in terms of the external forces. As the author says of admittances, "their use greatly facilitates the splitting of problems on mechanical vibrations into manageable portions", so that "the range of tractable problems is greatly extended".

The monograph contains an elementary exposition of the fundamental ideas, with examples of their application to a number of systems. The purpose is didactic, and the examples are 'academic', but the advantages of the method are clear to see, and students and designers should derive much profit therefrom. There are conceivably other topics upon which similar monographs might be included in the Reports and Memoranda Series issued by the Aeronautical Research Council, and Prof. Duncan may be congratulated upon creating an excellent precedent.

The electro-mechanical analogy is, however, not perfect, and the technique of mechanical admittances has not yet acquired all the facility of electric circuit theory. The idea of mechanical 'circuits' needs elaboration, and the analogues of Kirchhoff's laws would seem desirable, although the greater complexity of mechanical couplings and interconnexions does present some difficulties. W. G. BICKLEY

COLLEGE PHYSICS

College Physics

By Prof. John A. Eldridge. Third edition. Pp. x + 720. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 27*s*. net.

College Technical Physics

By Robert L. Weber, Marsh W. White and Kenneth V. Manning. Pp. x + 761. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 22*s*. 6*d*. 4.50 dollars.

THESE two text-books, designed for use in the first-year course of American colleges, are suitable for classes in Britain of intermediate degree examination standard, particularly where a combined course of instruction is given for students from various faculties. The subject-matter is similar in both, covering mechanics, heat, sound, electricity and magnetism, and optics. Calculus is not used, and only an elementary knowledge of algebra and trigonometry is required.

"College Physics", which is now in its third edition, first appeared in 1937. In the new edition a large part of the text has been rewritten, a slight change made in the order of presentation, and a greater number of worked-out examples given, though the problems at the ends of the chapters have not greatly altered. The author has tried to arouse an interest in physics and to make the student think for himself. In this he has succeeded admirably, but it is a pity that occasionally he has allowed his enthusiasm to run away with him, for some of his language is much too colloquial and his historical sketches very often ridiculous. The diagrams and explanations are very clear, and fundamentals are carefully stressed. The British 'gravitational' system (in which the unit of mass is the 'slug'), and the C.G.S. system of units are used.

"College Technical Physics" is a new book, although some of the material has been adapted from an earlier book of the authors entitled "Practical Physics". It is on conventional lines, with one unique feature—the chapter headpieces. These are portrait drawings by C. S. Hauschka—one for every chapter—of the fifty Nobel prize winners in physics, arranged in chronological order, from Röntgen in 1901 to Bridgman in 1946. Every portrait is accompanied by a brief biographical note. The portraits bear no relation to the chapters to which they are attached, nor is any reference made to the drawings in the text. Indeed, several of these eminent physicists, for example, Sir J. J. Thomson, who it is expected would be mentioned even in an elementary text-book, get no mention at all in the text. The book is very well produced and contains some excellent illustrations, both line drawings and half-tones. In particular, the chapter on colour, with its unusual but excellent coloured illustrations, must receive special commendation. S. WEINTROUB

The Electron Microscope

By Dr. V. E. Cosslett. (Sigma Introduction to Science, 8.) Pp. viii+128+12 plates. (London: Sigma Books, Ltd., 1947.) 7*s.* 6*d.* net.

THIS little book can be confidently recommended to those for whom it is written—the biologist and others seeking information about a new tool and the layman interested in recent scientific advances. It contains a non-mathematical account of the principles underlying the construction of an electron microscope. Starting with a description of the properties of an optical lens and the formation of an image by rays of light, the book proceeds to develop the analogy with electron lenses of both magnetic and electrostatic type. The account is at all times clear and simple; and the large number of illustrations and plates make the book easy to read and to understand.

The book concludes with two chapters on the present uses and future possibilities of the electron microscope. The first of these serves to emphasize the rapidity with which this new method of investigating the fine structure of matter has been exploited both in fundamental and industrial research. The second suggests that further developments are still possible and are being actively pursued. G. D. P.

Les mesures physiques

Par Albert Pérard. (Que sais-je ?, No. 244.) Pp. 136. (Paris: Presses universitaires de France, 1947.) n.p.

IN this paper-covered pocket edition, one of the well-known 'Que sais-je?' series, the director of the Bureau International des Poids et Mesures gives an authoritative, concise, and logical account of the important part played by measurement in science. The first chapter deals with the general principles and methods of measurement, and errors of observation. The following chapters discuss, in terms of the fundamental standards, the measurement of length, time and mass, and electrical measurements; and, since a knowledge of the temperature is essential for the exact specification of the fundamental quantities, a further chapter describes the methods used to measure temperature. The final chapter indicates briefly the principles of measurement of several other physical quantities, and an appendix tabulates equivalents of the principal units.

It is no easy task to deal adequately with the subject of measurement in such a small volume, and the author is to be congratulated on the skilful way in which he has chosen and handled his material. Unnecessary detail is avoided, and only a few absolutely essential references are given, so that even those possessing only a slight knowledge of physics will have no difficulty, when reading this book, in appreciating the basic principles and methods of physical measurement. S. WEINTROUB

Simple Experiments with Insects

By Dr. H. Kalmus. Pp. xii+132. (London: William Heinemann, Ltd., 1948.) 7*s.* 6*d.*

THE surest way to arouse interest in a scientific subject is to make it interesting; to perform actual experiments is one way of doing this. In this little book Dr. Kalmus describes more than a hundred experiments in insect behaviour and physiology for the benefit of amateurs or of school children and their teachers. The experiments range from such simple things as putting a bee in a bottle and showing that it produces water, or catching a fly in the hand, to quite difficult experiments such as the comparative rearing of *Drosophila* on synthetic media or studying the optomotor reactions of the mosquito. Even with the help of the short explanations which accompany the descriptions, it is unlikely that the amateur will grasp the significance of all the experiments; but many of them are well calculated to excite his interest, and the book should prove a useful complement to the observations of insects in the field. It is likely to be useful, too, for university teachers of zoology. A few errors may be noted: the yolk is not formed by the accessory glands (p. xii); hæmoglobin is not broken down beyond hæmatin in the mosquito (p.15); on p. 20 'gills' are called 'tracheæ'; on p. 83 the book louse is called *Anthrenus*.

V. B. WIGGLESWORTH

Guide to the Study of the Anatomy of the Shark, *Necturus*, and the Cat

By Prof. Samuel Eddy, Prof. Clarence P. Oliver and Asst. Prof. John P. Turner. Second edition. Pp. vii+115. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 12*s.* net.

THIS admirable little book, which was designed for students of the University of Minnesota, is accurately described in its title. It gives the salient features of the anatomy of the three animals with which it deals in the form of directions for their dissection. It has the virtue that it is concise, but one feels that students might have been helped by more detailed statements of dissection procedures. Unlike many British text-books, there is some treatment of the muscles; it is perhaps to be regretted that they were not a little more fully treated in the spiny dog-fish. The illustrations are rather few but they are clear and pleasant to look at; the last point is important, as increasing the likelihood that they will be studied. It would have been an advantage to have given some very simple sketches showing dissection methods. The book is clearly printed on thick paper, the pages held together between card covers by metal rings which enable the book to lie flat on a bench. P. D. F. MURRAY

The Psychology of Industry

By Prof. James Drever. Second edition, revised. Pp. x+151. (London: Methuen and Co., Ltd., 1947.) 7*s.* 6*d.* net.

THE appearance of a second edition of this work some twenty-six years after the original is a tribute to the work of a pioneer. During the First World War experimental psychologists made one or two attempts to show how science could appreciably add to the productivity of industry. By the time of the Second World War the more up-to-date industrialists had realized that the nineteenth-century stress on material and monetary factors in industry had been greatly overdone and that efficiency could only be approached when as much attention was paid to the human factor. Prof. Drever's book is a record of the work done by himself and other investigators between the two wars. While it pays little attention to developments in industrial relations since that time, it is still a worthy guide for all who are seeking to provide optimum satisfaction to workers in industry and, concurrently, to raise the overall level of industry's productive capacity.

T. H. HAWKINS

THE ROLE OF CHEMISTRY IN COMBATING TROPICAL DISEASES*

By Sir IAN HEILBRON, F.R.S.

TO a great Colonial Power such as Britain, the control of the insect-borne diseases, malaria and trypanosomiasis, the vectors of which are respectively the Anopheles mosquito and the tsetse fly, is of paramount importance. Malaria, which claims anything from 300 to 800 million victims a year, with an annual death roll of 3 to 4 million, is the most prevalent of all human infectious diseases and the worst scourge with which we have to contend throughout all our tropical and sub-tropical Colonies. It is not only responsible directly for enormous damage to health but it so lowers vitality by its destruction of blood cells that other infections are enabled to create perhaps even greater destruction than the malaria itself.

The direct cause of all this sickness is a protozoon belonging to the genus *Plasmodium*. Of the three species, *P. vivax*, *P. falciparum* and *P. malariæ*, concerned, each produces distinctive symptoms and requires different treatment. They are injected into the blood of humans by the females of Anopheline mosquitoes during their act of sucking blood upon which they live. Of the hundred and forty or so different kinds of Anopheline mosquitoes, fortunately only about fifteen of these are important vectors of malaria. Thus in Africa the main carriers are *Anopheles gambiæ* and *A. funestus*; in America they are *A. quadrimaculatus*, *A. punctipennis* and *A. crucians*; and in India, *A. stephensi*, *A. culicifacies* and *A. rossi*, and so on.

Trypanosomiasis, or sleeping sickness, unlike malaria, is confined to Africa. Human sleeping sickness is caused by two species of trypanosomes, *T. gambiense* and *T. rhodesiense*. The latter produces a virulent type of the disease particularly difficult to control by drugs. The trypanosomes responsible for trypanosomiasis among domestic animals differ from those affecting humans. Of veterinary importance, mention may be made of *T. congolense* and *T. vivax*, of which the former is much the more virulent among cattle and presents the most serious veterinary problem. *T. brucei* is generally fatal to horses, while *T. simiæ* is a strain particularly dangerous to pigs. The organism responsible for transmission of the disease is the tsetse fly. Among the many species of tsetse, *Glossina morsitans* and *G. pallidipes* range over wide areas of bush, scrub and forest country and are found in all altitudes up to about 5,000 ft. A fly of a different habitat is *G. palpalis*, which generally lives in the proximity of water.

For Africa, especially equatorial Africa, trypanosomiasis is just as grave a problem as malaria, for where tsetse rules uncontrolled, domestic animals cannot exist, and thus vast tracts of valuable grazing land which fall within the fly-belt are left unstocked and uninhabited. As a result, the number of cattle in Africa is tragically small, but even so over-grazing occurs in many areas. In turn, the human population suffers from a deficiency of animal protein, the soil loses fertility due to lack of manure and generally conditions are created wherein disease, poverty and misery alone thrive.

Malaria and trypanosomiasis constitute, without doubt, the biggest hindrance to the economic, social and political development of those territories afflicted by them. Until control of these diseases is effected, we cannot reasonably expect native communities to be sufficiently vigorous, either physically or mentally, to be entrusted with the many responsibilities which the rapid imposition of our social and political systems must throw upon them.

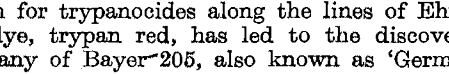
There are two distinct approaches to the problem. We can attempt either to destroy the parasites in man and animals, or we can concentrate our attention on the eradication of the vectors themselves. Both lines of investigation have been actively explored with considerable success for many years.

The search for synthetic drugs for combating both malaria and sleeping sickness has been pursued with increasing tempo ever since Paul Ehrlich, the brilliant founder of modern chemotherapy, established in the first years of the present century the principle that infectious diseases could be cured by employing specific chemical agents to bring about the selective destruction of the invading parasites.

Chemotherapy of Human and Animal Trypanosomiasis and of Malaria

With the experimental production of trypanosomiasis in mice and rats by Laveran and Mesnil in 1902 and the demonstration by Thomas in Liverpool in 1905 of the trypanocidal activity of atoxyl (I), Ehrlich decided to focus his attention on compounds of arsenic, rather than pursue his studies on purely organic compounds where some promising results had already been attained in mouse trypanosomiasis with a dyestuff, trypan red. As is well known, the culminating point of this series of investigations was the discovery of 'Salvarsan' (II) by Ehrlich and Hata in 1910 as a cure, not for sleeping sickness, but for the spirochætal infection syphilis. For human sleeping sickness the most successful and widely used arseno-organic compound is still 'Tryparsamide' (III), first described by Jacobs and Heidelberger in the United States in 1919. Its virtue lies in the fact that it is the only drug with any action in the deadly late stage of sleeping sickness when trypanosomes have penetrated into the central nervous system.

[I]



[II]

[III]

Turning now to purely organic compounds, the search for trypanocides along the lines of Ehrlich's azo dye, trypan red, has led to the discovery in Germany of Bayer 205, also known as 'Germanin', 'Suramin', 'Antrypol', etc. This substance represents the most successful chemotherapeutic agent so far discovered for human sleeping sickness in its early stages. A single dose confers a trypanocidal power on the blood for a long period, while resistance of trypanosomes to it is acquired more slowly than with

---

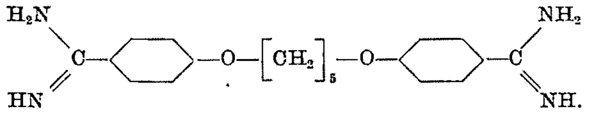
[IV]

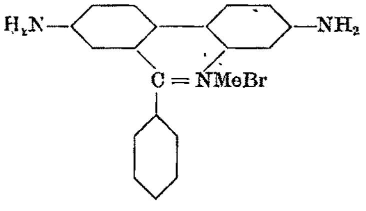
arsenical preparations. Furthermore, it is of value against *T. rhodesiense*, where arsenicals are ineffective. On the other hand, it is of no use in the later stages of the disease, and this seems to suggest that it cannot penetrate the blood-brain barrier.

Another highly important group of chemotherapeutic agents for human sleeping sickness are the diamidines, which have been developed in Great Britain following upon an investigation of Lourie and Warrington Yorke in Liverpool. Among the members of this series, pentamidine (V) is used on a large scale by Belgian, British and French medical services. It is an extremely powerful trypanocide for treatment of the disease in the lymphatico-blood stage, but like 'Suramin' is ineffective in cases of severe nervous involvement.



[V]

Until recently, the search for synthetic drugs effective against the dreaded *T. congolense* infections in cattle has been unsuccessful and only tartar emetic and certain other antimonials have been found of any value. In 1931, Morgan and Walls, working in the Chemical Research Laboratory, Teddington, discovered a new series of phenanthridinium compounds, among which certain members were found to possess strong trypanocidal properties. Of these, dimidium bromide (VI) (phenanthridinium 1553) is quite outstanding and appears to cure *T. congolense* infections at extremely low dosage.



[VI]

The use of the drug is, however, not unattended by danger, as it is toxic and produces in cattle photosensitization if used in large amounts.

As a result of the world-wide distribution of malaria, the subject of specific therapy has commanded a great deal of attention. This was particularly the case during the Second World War, when both British and American troops were operating in some of the worst malarious spots in the world. The position was aggravated by the fact that quinine, the ordinary prophylactic and curative drug, became unavailable in consequence of the Japanese invasion of Java, which cut off our supplies of cinchona bark.

The possibility of studying the effect of drugs upon the malaria parasites was opened up when Roehl, one of Ehrlich's pupils, developed a method in 1926 of transmitting a related infection, *Plasmodium relictum*, to canaries. Following upon this discovery, chemical research work was actively pursued and rapidly resulted in the discovery in Germany of 'Plasmoquin' (VII) ('Pamaquin'), followed shortly afterwards by that of 'Atebrin' ('Mepacrine') (VIII) in 1930 This latter compound has proved to be a more effective suppressive than quinine, and its manufacture in Britain was begun during the War. The discovery by Curd, Davey and Rose of the important antimalarial 'Paludrine' (IX) in 1944 as a result of brilliantly planned war-time research in the laboratories of Imperial Chemical Industries, Ltd., at Blackley, marks a still further striking advance in chemotherapy. As is seen from the formula, 'Paludrine' is an entirely novel drug quite unrelated structurally to either 'Pamaquin' or 'Mepacrine'. Unlike the latter, it is colourless and hence produces no discoloration of the skin. At the same time, it is less toxic, and both for prophylactic and curative purposes is vastly superior.

[IX]

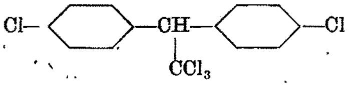
Attacking the Insect Vector

No one can question the great importance of the use of drugs for the treatment of either malaria or trypanosomiasis; but it is well recognized that in our Colonial territories with their many tribal communities, or in India with its teeming population, there is as yet no practical possibility of stamping out insect-borne diseases by such methods. The only alternative is to secure control by exterminating the vectors.

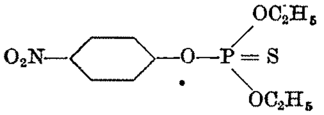
The idea of eradicating malaria and sleeping sickness in this way is, of course, not novel. The attack upon the mosquito by the drainage of swamps, the spreading of oil on water and the use of Paris Green for dusting to kill larvæ, and the spraying of houses with pyrethrum extract in kerosene are all methods which have been practised for a great many years. In 1930, a serious epidemic of malaria broke out in Brazil due to the introduction of *Anopheles gambiæ* into that country, probably by sea, from Africa. An area of 12,000 square miles was affected, but through the joint co-operation of the Brazilian Government and the Rockefeller Foundation complete eradication of the species was attained. Similarly in 1942, *A. gambiæ* spread from Central Africa into Egypt, causing a serious epidemic of malaria. The Rockefeller Foundation experts were again called upon to assist the Egyptian Government. Paris Green was employed as the principal insecticide and applied to all potential breeding places. House-to-house spraying with pyrethrum was also employed throughout the whole of the infested area. By 1945 the area was free from infestation. I mention these two campaigns as they serve to demonstrate what can be achieved by careful planning. The cost both in money and labour was high, but the extermination of the disease-carrying mosquitoes was achieved.

With the discovery of the newer and almost unbelievably potent insect-killing chemicals D.D.T. (dichlorodiphenyl-trichloroethane) (X) and benzene hexachloride ('Gammexane') the whole scheme of things has, in my opinion, become transformed. We have in these substances enormously powerful weapons for the waging of successful war against the mosquito, the tsetse and other vectors of human diseases.

So much has already been written about these two insecticides that it is unnecessary for me to do more than recall the fact that, like pyrethrum, they are contact poisons; but unlike the natural material which rapidly oxidizes in air and so loses its potency, D.D.T. is a comparatively stable substance remarkably resistant to oxidation, and thus capable of exerting insecticidal effects upon sprayed areas for prolonged periods. In addition to the above substances, many other powerful synthetic insecticides and miticides of promise have been produced in the United States. Of these, mention may be made of 'Chlordane', a chlorinated indane derivative, and 'Thiophos 3422' ('Parathion') (XI), which is said to be more effective against a wider range of insects and mites than any chemical now in practical use, and a series of alkyl polyphosphates originally prepared in Germany as a substitute for nicotine under the name 'Bladon'.



[X]



[XI]

Many experiments on insect control are being carried out in British Colonies, either by the respective Colonial administrations themselves or in conjunction with the Colonial Insecticide Committee set up by the Secretary of State for the Colonies, Mr. Creech Jones, at the beginning of 1947.

Although D.D.T. was used so extensively and with such success during the War both by the Americans and ourselves, we were by no means satisfied that we were employing it to the best advantage. Thus we commonly used a 5 per cent solution in kerosene simply because kerosene was readily available, and we had failed in our attempts at that time to obtain good emulsions or wettable powder. Similarly, we lacked precise information as to the best methods of spraying and made do with what equipment was available. Thus in the case of aircraft sprays, use was made of equipment originally designed for gas warfare.

Even to-day, comparatively little is known of the performance in tropical countries of fixed-wing aircraft as a means of disseminating insecticides, and nothing of the efficiency of the helicopter for that purpose. Experiments on these lines are now about to be conducted in Uganda and Tanganyika using a variety of insecticide formulations, including smokes, oil solutions, emulsions, water suspensions and aerosol fogs. Much research has also to be carried out on such unsolved problems as the causes and prevention of absorption of insecticides by mud and thatch, the absorption and decomposition of insecticides by green leaves, the use of surface-active agents to help the spray wet the leaves and insects, and the relationship between crystal size and toxicity. These and many other questions that have arisen during field trials necessitate studies of a fundamental nature which can only be satisfactorily undertaken by a team of scientific workers, including chemists, physicists, biologists, chemical engineers and other specialists. The Colonial Insecticide Committee, with the co-operation of the Ministry of Supply, is therefore establishing a research unit at Porton to undertake the necessary investigations.

In the meantime, large-scale experiments are in hand. The first of these was initiated in 1945 in British Guiana, where more than 70 per cent of the population, some 250,000 people, live under conditions of severe endemic malaria. The initial work was directed by Mr. C. B. Symes, now officer in charge of research for the Colonial Insecticide Committee, and was later taken over and expanded by the Government malariologist. Before spraying was commenced, 700–800 mosquitoes would be found in one small bedroom. These included not only the malaria carrier, *Anopheles darlingi*, but also *Culex fatigans*, which are carriers of filariasis, and *Aedes ægypti*, which are potential carriers of yellow fever. Spraying was carried out with 5 per cent D.D.T. at a dosage of 100 mgm. per sq. ft. to the inner surfaces of dwellings. After as long as ten months and using only a single spraying, *A. darlingi* mosquito captures were down to less than 2 per cent of the numbers in untreated huts. To date, approximately 84 per cent of the population are enjoying total protection from malaria. In one village where more than 60 per cent of school children showed chronic infection by malaria in 1945, only 18 per cent were infected in 1946. In 1938 the spleen index in school children was 51·2, whereas in 1947 it had fallen to 3·7.

Another highly successful experiment is being carried out in Cyprus. In the past, various efforts have been made to control the disease by treatment of water areas with oil and with Paris Green, but without success. In 1946 a large trial was conducted in the Karpass Peninsula over a total area of some

7,000 square miles. The attack, directed by Mr. M. Aziz, the chief health inspector, was concentrated upon larvæ in water courses, pools, wells, etc. Spraying was carried out in most places every fourteen days from April to the end of October, when *Anopheles*, both adult and larvæ, were completely eliminated from the area. The work was being extended in 1947 and it was confidently anticipated that the complete eradication of mosquitoes from Cyprus could be expected within two or three years.

A malaria eradication experiment is now being prepared to be conducted in the island of Mauritius, commencing in the autumn. Malaria was introduced into the island about 1862 and is now endemic. The disease is the principal cause of death in the Colony, the population of which is about 420,000. Most of the infection is due to *A. funestus*, supplemented by *A. gambiæ*. Apart from the highest part of the island, which excludes some five thousand houses from a total of eighty-three thousand dwellings, all houses and cattle and goat sheds in the remainder of the island are to be treated by the application of residual insecticidal formulations three times a year over a period of two years. If necessary, the extension of spraying to breeding grounds will be put in hand.

Large trials are also in progress in East Africa. These are being conducted by the Colonial Insecticides Research Unit in Uganda, and cover both work on mosquitoes and tsetse flies. An interesting field experiment was carried out in a rural area north of Entebbe in Uganda, in which some two thousand houses of the mud wall and thatched roof type were divided into six areas and treated with six different formulations of D.D.T. and benzene hexachloride. All treatments caused striking reductions in populations of mosquitoes in houses. Four sprayings prevented the usual seasonal increase of malaria, and two of these apparently resulted in a reduction of malaria by about 50 per cent. These results were obtained over two wet seasons.

An important factor in field trials is the reaction of the people to the experiments, especially as they involve removal of foodstuffs, clothes, etc., from the rooms to be sprayed. Actually Mr. Symes relates that the reception everywhere was so good that at times it became embarrassing. For the first time in their lives these people experienced an undisturbed night's sleep, free from the evil presence of hundreds of biting mosquitoes as well as bed bugs, 'chigger' fleas which burrow under the skin and nails of feet and hands and cause septic sores and many other pests.

Tsetse Flies

Interesting and promising results have also been obtained in field experiments with insecticides conducted by the Uganda research team on the tsetse-infested islands and shores of Lake Victoria (in Central Africa), by the South Africans in South Africa, and by the East African Tsetse Research Department in Tanganyika. Tsetse flies, both males and females, live by sucking the blood of animals, including domestic animals and man, where these are available, and they breed and live in bush (or jungle) of various kinds. Their young spend all their development period—some eight weeks upwards—in the soil, so that they are difficult to get at. It is the adult fly, therefore, while it is resting on leaves, tree-trunks and stones in the bush, or actually in flight looking for food, or while feeding on an animal, that is vulnerable to attack with insecticides.

Two obvious methods are the spraying of the bush and the spraying of cattle with contact insecticides. The first method has been tried on a number of small islands of 100 acres or so and on stretches of dense shore bush on Lake Victoria. Solutions and emulsions of D.D.T. and benzene hexachloride were applied with small knapsack sprayers to bush in places where the flies concentrated or patrolled. In order to do this and to do the necessary preliminary survey of fly densities, paths were cut through the bush. It was, of course, possible to spray only a small proportion of the total bush in this manner. In spite of this, the reduction in the fly population in the last few experiments was about 98 per cent. In one trial no flies could be found for nearly three months after the last of four sprayings. While this work was going on, it was discovered that the oil solutions that were being used appeared to lose their effect on flies after about a week because a very large proportion, sometimes as much as 80 per cent, was absorbed by the leaves and stems of the trees and bush. One of the urgent inquiries, therefore, is now to find formulations of D.D.T. and benzene hexachloride that will not be absorbed by plants and trees, and it seems that certain types of emulsions or wettable powders may suit in this way.

Since such a large proportion of the total flies were killed by treatment of so small a proportion of the bush, it is thought that by increasing the area sprayed, even the last 2 per cent of flies will have difficulty in escaping. It is proposed, therefore, to do this, and since no known type of ordinary spraying equipment is suitable for use in these large areas of dense bush, the spray is to be applied from aircraft. Extensive trials of this method are now planned to begin in a few months.

Trials of insecticidal smokes and fogs drifted through the bush have also been conducted with very promising results. The smokes have been produced from grenades and canisters, filled with burning mixtures and the insecticides mixed together. The fog was discharged from a special machine.

The South Africans have gone further than this with trials of insecticidal smokes for the control of tsetse flies (*G. pallidipes*). For the past two years or so they have used aircraft for this work and have treated about 170 square miles several times with smoke made from a 20 per cent solution of D.D.T. in toluene and fuel oil. The aircraft fly just above the tree-tops and the smoke is produced from their exhaust pipes, which are connected to the internal spray-tanks for this purpose. Kills of tsetse have been good over the areas as a whole (up to more than 99 per cent), but small numbers of flies have been left unharmed in dense evergreen thickets to which the smoke has not penetrated. These small pockets are now being dealt with by means of smoke canisters. South Africa has expended more than £300,000 and much effort on this work, and has had the full co-operation of its Air Force. The British effort has been much less costly so far, but it is likely to build up to a similar order of magnitude in the near future—in fact it must, if we are to deal with this problem in anything like an adequate fashion.

There is a second method of application, namely, the spraying of cattle with insecticide so that flies settling on them to feed come into contact with the insecticide crystals and so are affected. This has been tried by the Tsetse Research Department of Tanganyika. After preliminary work, they sprayed 350 cattle once a week for thirteen weeks and then twice a week for another eight weeks with 9 per cent D.D.T. solution in monkeynut oil plus resin. The cattle after each spraying were herded in small groups of five or six over an area of about five square miles of bush infested with the tsetse (*G. pallidipes*). At the end of this period the tsetse had been reduced by about 80 per cent. During this work it was found that the solution when applied to cattle lost its toxicity in a few days, though the same solution applied to a dried ox skin was toxic for months. Subsequent investigation has shown that this is due essentially to absorption of the solution into and through the living skin. This line of investigation will continue.

Effective application of insecticides is not quite the simple problem that it may seem. Chemical, biological, physical and engineering studies are all deeply involved and intermixed. It is only in so far as we are able to cope with these interrelated problems that we may expect to make progress. Our effort so far, however promising—and the results are very heartening—is a very meagre one. We in the British Commonwealth of Nations are faced with all the major insect-borne diseases and pests of animals and crops in larger measure than any other group of peoples. In the past there has seemed to be no way of dealing with these problems in any reasonable period. But with the new insecticides, supplementing the best of the old, we have weapons of which we have not hitherto dreamed. The future holds a challenge which we dare not refuse.

THE HEALTH OF THE SCHOOL CHILD

By Dr. ROBERT SUTHERLAND

Medical Adviser and Secretary, Central Council for Health Education

NOT the least of British war-time triumphs was the way the health of the children was maintained and even improved. Except in 1940–41 the death-rates in the war years were equal to or less than pre-war rates. There was an improvement in the height and weight of both sexes, the number of children with really bad nutrition was roughly halved, and the amount of anæmia was reduced.

These striking improvements took place although many children suffered the stresses of air raids and the disruption of evacuation, and although the staffs of school medical and school dental services were reduced because many of their members were serving in the armed forces.

There is no doubt, therefore, that these encouraging results were largely due to a raising of the standard of living of the poorer half of the population, to our very well-designed system of rationing, with its priorities for mothers and children, and to the tenfold increase in school dinners and the 30 per cent increase in the taking of school milk.

Part of the fall in the death-rates was due to a reduction in deaths from respiratory infections, notably pneumonia, and from diphtheria. The development of chemotherapy probably had much to do with the fall in pneumonia deaths, and the diphtheria immunization campaign introduced in 1942 was certainly largely responsible for the striking reduction in the diphtheria deaths.

The report of the Chief Medical Officer of the Ministry of Education for the years 1939–45* very properly stresses the ground that has been gained in difficult circumstances. But equally properly Sir Wilson Jameson notes some challenging facts that still confront us.

The nutrition of one out of every six (or at best one out of every nine) of our school children still leaves something, and in many cases much, to be desired. Despite the fact that the pre-school child is in many ways the most cared-for citizen, only one in five of our five-year-olds has had no dental decay: the average child aged five has four teeth missing, filled or decayed.

In some places one in ten of the children in our schools are educationally sub-normal, and—evidence of poor environment or poor parental care—one in ten children have head lice or nits.

Nutrition, of course, is a very complex matter which depends on much more than diet. Insufficient sleep, infectious diseases of childhood, lack of exercise, unhappiness, insecurity, all prevent a child from getting full advantage from his diet. Since less than half the mothers in Britain, however, get for their children the vitamin extras to which they are entitled, it is probable that the diet is not always as good as it might be. Nine-tenths of school children are now getting school meals, and there is little doubt that as a consequence we shall, over a period of years, see a considerable improvement in their nutrition; but, of course, no official provision is at present made, except in nursery schools, for well-balanced meals for the pre-school child. Although the school child gets one-third of a pint of milk a day entirely free of charge, milk for the pre-school child (except in cases of great need) has to be paid for, although at a cheaper rate.

It is certainly an indictment of our separation allowances for the dependants of Service men that the children of Service men showed a lower amount of hæmoglobin at all ages less than ten years.

Many of the 10 per cent of children who are educationally sub-normal are merely backward as a result of poor health or poor nutrition, so that here there is a close relation between the child's intellectual and physical health. Indeed, since in some cases a child may fail to use his intelligence principally because of emotional disturbances, emotional health is involved as well. The importance of emotional health is indeed recognized in the report, and developments of the Child Guidance Service are forecast. There are, too, throughout the report many indications of a clearer recognition of the child's unity of mind and body and of the consequent need for the closest possible co-operation between the teacher, doctor and nurse; and considerable space is given to a consideration of how physical education and health education can help.

The importance of the home and of factors outside the home is rightly stressed. However much school meals are developed, and other existing responsibilities of the parent taken over by the teacher or the school doctor or nurse, the health of the school child will still be largely determined by the care given him in his home. Nevertheless, the extension of the school's responsibility increases the influence of the school in health as well as in education.

---

* The Health of the School Child. Report of the Chief Medical Officer of the Ministry of Education for the Years 1939–1945. Pp. 148. (London: H.M. Stationery Office, 1947.) 2*s.* 6*d.* net.

The whole report points strongly by implication to the need for a more dynamic and functional approach to school medicine.

One looks forward to the day when the school medical officer is an integral member of the school staff, whose duty it is to study the child at work and at play in the changing school setting. With its demands upon the child's senses and its opportunities for expression—intellectual, emotional and social—aspirations and powers, the school offers probably unique opportunity for the study of the functioning of the total child. The study of health in this dynamic sense would surely be much more profitable than the present sporadic and static methods of school medical inspection.

INDUSTRIAL FIBRES

BEFORE the Second World War, the Commonwealth Economic Committee issued annually a series of reviews which summarized the main facts of production, international trade and consumption for various important animal and plant commodities. These reviews are now being re-issued for the war and post-war years. Among the first to reappear is the volume on "Industrial Fibres"*, which surveys the world situation with regard to cotton, wool, silk, flax, jute, hemp, mohair, coir and rayon. While the data for several countries are not yet available, the information gives a broad indication of changing trade patterns. The main change has been the redirection of foreign trade caused by the dislocation of normal trading channels and the development of alternative sources of supply. The United Kingdom remained the chief importer of industrial fibres, although, after 1941, the United States imported most wool, some of which was accumulated as reserve on the United Kingdom's account. Imports into the main European countries and Japan were greatly reduced during the war years.

The world production of fibres at first expanded but soon declined sharply, reaching a minimum in 1944, with moderate recovery in 1946. Output was generally restricted to cover essential war purposes, and civilian consumption of textiles was curtailed. Where production exceeded demand, as in wool and cotton, stocks accumulated, thus increasing the supplies available in the post-war period. The recovery in 1946 continued in 1947, but future expansion will depend on changing conditions in Germany and Japan. There has been no significant modification in the post-war pattern of production of the different fibres compared with pre-war years, with the exception of rayon, which is now being mainly produced in the United States. Comparing production in 1945 with that in 1938, wool has declined least, namely, 2 per cent; rayon yarn has declined 11 per cent; cotton 26 per cent; staple rayon fibre 45 per cent; and silk 73 per cent. The serious decline in cotton production was caused mainly by the transfer of cotton-growing land to food production, particularly in India and the United States. Silk production was largely suspended in Japan during the War. In 1946, wool alone showed a small decline over the 1945 figure, but world stocks are still large. Rayon made good the war-time losses and rose 10 per cent above the 1938 figure. Cotton and staple fibre production also showed improvements but silk expanded only slightly, being in 1946 only 27 per cent of the pre-war figure.

The contribution made by the British Commonwealth to the world's production of fibres is considerable. Thus nearly all the world's jute, nearly half the world's wool, more than a quarter of all its hemp and nearly a fifth of its cotton are produced in the Commonwealth, which is still an exporter of these fibres, having built up surplus stocks before the War. The 1946 export balance for wool was the highest ever recorded; for jute and hemp it was about one-half of the pre-war figure. The war-time dependence on foreign supplies of rayon, silk and flax (imported on balance before the War) has now been lessened, but dependency on outside sources still applies to cotton.

The significance of industrial fibres in the exports of different Commonwealth countries has been amply maintained during the post-war period. For example, wool accounted in 1946 for 33 per cent of the total exports of South Africa, other than gold, as compared with 30 per cent in 1938 and only 6 per cent in 1944. Jute and jute products made up nearly 30 per cent of the exports from India in 1946, which were 24 per cent in 1938. Hemp reached 44 per cent of the exports from Tanganyika in 1946 as against 38 per cent in 1938.

Cotton. The main sources of cotton for world trade are the United States, India, Brazil and Egypt. In addition, Russia and China also grow large quantities of cotton but consume most of it domestically. The chief importers of cotton before the War were Japan and the United Kingdom, which used up nearly half the total production, other European countries consuming the rest. Production declined from 17,900 million lb. in 1938 to 10,000 million lb. in 1946, but consumption fell even more, so that stocks rose from 10,400 to 13,500 million lb., but have since fallen to nearly half this amount. Long-staple varieties are being increasingly grown in most of the chief areas.

Wool. This is produced as a main product in merino sheep farming or as a secondary product to meat in the rearing of crossbreds. A dry summer greatly reduces the output of fine merino wool. The rising trend in number of sheep before the War was reversed in 1941, and the decline was accentuated by the Australian drought of 1944–45. World production of wool fell rapidly after 1942, especially in the United States and Australia, and to a lesser extent in South Africa. Australia still retains its position as the leading wool-exporting country and usually exports more than twice as much wool as any other country. The chief importing country until 1941 was the United Kingdom, but since that year the United States has assumed first place. Lack of production statistics for *mohair* renders it difficult to assess the changes in world supplies over the war period.

Silk. Before the War, some 100 million lb., or 80 per cent, of the world's silk was produced in Japan. Since 1941, the production has diminished rapidly until, in 1946, Japan produced only 12 million lb. of raw silk. Even before the War, production was declining through increasing competition with rayon and nylon, which may eventually supersede natural silk.

---

* Industrial Fibres. Summary of Figures of Production, Trade and Consumption relating to Cotton, Wool, Silk, Flax, Jute, Hemp, Mohair, Coir and Rayon. Compiled in the Intelligence Branch of the Commonwealth Economic Committee. Pp. 137. (London: H.M. Stationery Office. 1948.)

Flax. The best flax is produced in temperate regions such as Europe. In certain countries, the plant is grown primarily for linseed, the fibre being a relatively expensive by-product. Reliable information concerning the world's flax industry is difficult to obtain because of this dual-purpose objective. The output of flax appears to have declined by some 70 per cent up to 1945 and has since shown only a moderate recovery. Considerable reduction in output has occurred in Russia, Poland, Belgium and Holland, whereas it has expanded in Egypt, Australia, New Zealand and Canada. Cotton, jute and rayon are proving to be serious competitors of flax, partly because of the high price of linen goods.

Hemp. The chief hemp-producing countries before the War were the Philippine Islands (manila bast fibre, used for marine cordage), the Netherlands East Indies and Tanganyika (sisal bast fibre, used for binder twine), Eastern Europe and Russia (true, leaf hemp, used for twine and cord). World output of bast (or 'hard') hemps fell considerably through the effects of the War in the Far East, although the output in Tanganyika was maintained, and of leaf (or 'soft') hemp in Europe and Russia through curtailment of the area on which the crop was grown.

Jute. Most of the world's jute is grown in Pakistan, but the greatly increased home demand for sacking has brought about a marked reduction in exports. The jute mills and the main port (Calcutta) are situated in the Dominion of India, and future development of the jute industry will depend on the conditions of inter-trade between the two new Indian Dominions. The largest importer of jute is the United Kingdom, although present stocks are low.

Coir. The only important world-producers of coir (coconut fibre) are India and Ceylon, where the industry is carried out as a part-time occupation of villagers, who also utilize a large proportion of the material. The mobilization of native labour for war purposes in these two countries has led to reduced coir production during the past eight years.

Rayon. The output of rayon yarn has been maintained in recent times, despite the collapse of Japan, by the large increase in production in the United States, which has more than doubled since 1941. By 1946, the United Kingdom had become the second largest producer and the second largest exporter. Rayon depends for its raw materials on the supply of wood pulp or cotton linters. The filaments are reeled to produce 'filament yarn' or spun on to spindles to produce 'staple fibre'. The former competes with natural fibres; the latter s an intermediate product which is becoming increasingly important as an admixture to the natural fibres.

OBITUARIES

Prof. F. A. A. Lacroix

On March 16 there passed out of the scientific life of Paris a great figure and one whose scientific writings have been read by mineralogists and geologists the world over for the past sixty years. François Antoine Alfred Lacroix, 'secrétaire perpetuel' of the Paris Academy of Sciences for thirty-four years and professor of mineralogy at the National Museum of Natural History during 1893–1936, was born at Maçon on February 4, 1863, and died in Paris on March 16. He studied at the *lycée* of his native town, at the Sorbonne, and at the Collège de France. He commenced to study pharmacy but soon was attracted to geology and mineralogy, and in 1887 was appointed 'préparateur' at the Collège de France and a collaborator on the French Geological Survey. Before he was thirty he succeeded Des Cloizeaux as professor of mineralogy at the Natural History Museum. He added many fine specimens of minerals and a superb collection of rocks to the Museum collections. In this he was assisted by many of his pupils, mining engineers and government officials in France's overseas possessions who, catching the enthusiasm of the master for his science, seem to have been ever ready to gather materials for his scientific work and for the national collections.

On his appointment to the Museum, Lacroix commenced at once a great work on the mineralogy of France and her Colonies: its fourth volume was completed in 1913. In these volumes he described the associations and paragenesis of the minerals as well as their crystallography and optical properties. A separate work in three volumes on the mineralogy of Madagascar was published in 1922 and 1923. This included a wealth of detailed petrology and many new analyses of rocks as well as descriptions of the minerals. In this book he developed his classification of igneous rocks, a modified form of the American quantitative classification. In later years he devoted more time to petrology than to descriptive mineralogy, and published a great many papers describing the rocks of many regions, and introducing, sometimes in very brief papers, ideas of considerable importance. Meteorites and tektites—the mysterious glass bodies supposedly of meteoritic origin—were also subjects of his research and were described in important memoirs. To geologists Lacroix will be best known for his early work on the granite of the Pyrenees and its contact phenomena (1898–1900), and for the well-illustrated memoirs recording his observations on active volcanoes in several parts of the world, including especially Mt. Pelée, Vesuvius and Réunion.

In addition to all his mineralogical work, Lacroix devoted an immense amount of time to the affairs of the Academy of Sciences, working at the development of its library and the classification and enrichment of its archives, gathering together letters and other documents of great interest. He published biographies of many mineralogists. His two-volume history of the life of Déodat Dolomieu appeared in 1921, and in 1928 a historical note on the distinguished occupants of the 'chair' of the section of mineralogy of the Academy from Nicolas Desmarest (1795) to Lucien Cayeux (1928).

In all his work Lacroix had a sympathetic and devoted companion in his wife, Catherine Fouqué, daughter of the geologist, Ferdinand A. Fouqué, with whom Lacroix worked in his early years. Madame Lacroix accompanied her husband on many of his travels, visiting with him many active volcanoes. Their married life was extremely happy, and their home had a charm which touched all who were admitted to their friendship and their hospitality. Madame Lacroix died in 1944 and Lacroix never completely got over it; but still he remained enthusiastic and immensely active, and went daily to the museum and the Academy. To the end of his life he was surrounded by devoted friends and colleagues. Many geological societies had done him honour during his life-time and many tributes have already been paid to his memory. The president of the Paris Academy of Sciences, in announcing Lacroix's death to the members, described him as a man who had devoted his whole life to science and "qui restera dans la mémoire comme un des représentants les plus admirables de ce que peut donner, dans notre race, l'association d'un génie scientifique de premier ordre, avec un de ces caractères incorruptibles qui sont l'honneur de l'humanité". W. CAMPBELL SMITH

Dr. E. P. Harrison

DR. E. P. HARRISON, for many years professor of physics at Presidency College, Calcutta, and head of the Observatory, and later chief scientist to the Mine Design Department in H.M.S. *Vernon*, died suddenly at Chigwell Row, Essex, on May 6.

Born in London in 1877, he was the eldest son of Robert William Harrison. His school career was much interrupted by illness, but he entered University College, London, where he won the Clothworkers' Exhibition, and an 1851 Exhibition Research Scholarship in physics. From London he went to the University of Zurich, where he took a Ph.D. in science. In 1904 he went up to King's College, Cambridge, as an 'advanced student', and worked at the Cavendish Laboratory for two years. He lectured at King's College, London, and the Royal College of Science, Dublin, and was then appointed professor of physics at the Mahommedan College of Aligarh in India. Afterwards he was appointed to the Indian Educational Service, and became professor of physics at the Presidency College, Calcutta, and later, in addition, meteorologist to the Government of Bengal.

In 1923, he became chief scientist to the Mine Design Department, H.M.S. *Vernon*, a post which he held until his retirement under the age limit in 1937. His work during this period naturally received no publicity; but under his direction the application of scientific research to the problems of naval mining, begun in the First World War, under the inspiration of, among others, W. L. Bragg, F. E. Smith and G. W. Walker, was continued and extended, and the results he achieved bore good fruit when another war came. He was happiest when working in a laboratory, and never allowed the responsibilities of administration to keep him from active research.

Among Dr. Harrison's personal contributions to naval problems were pioneering work in the application of magneto-striction to the generation of high-frequency sound in water, and the investigation of various properties of the high-permeability alloys of the 'permalloy' group. Perhaps the most interesting of these are the very large changes of impedance which occur in a wire carrying audio-frequency A.C. when small longitudinal magnetic fields are applied to it. An account of fundamental work on this effect was published by Dr. Harrison and members of his staff in 1936, and a practical application was a novel form of magnetometer which was used before the War, in anticipation of the use by the enemy of magnetic mines and torpedoes, to explore the possibilities of controlling the magnetic fields of warships by current-carrying cables. This was probably the earliest practical essay in 'degaussing'. During the War the magnetometer was developed on behalf of the Admiralty by the Electrical Research Association, and became a standard measuring instrument on degaussing ranges.

On leaving the Admiralty, Dr. Harrison joined the staff of Messrs. Hughes and Sons, of Barkingside, and arranged to continue the work he had begun earlier on magneto-striction in H.M.S. *Vernon*. The original oscillators made by him were developed by the firm, and a large number of experiments were made with listening devices off Gourock pier, which led to increased sensitivity.

The outbreak of war attracted his attention to the detection of mines, either floating or submerged, by supersonics, and very valuable data were collected. Later he did much work, both in the laboratory and in trials at sea, on non-contact firing devices for torpedoes.

Dr. Harrison was a physicist in the classical tradition, and had a very keen brain which he applied with great zest to new technical arts of war and peace. He had a large circle of friends, and will be greatly missed for his constant kindness and help to young scientific workers.

NEWS and VIEWS

The King's Birthday Honours List

THE following names of men of science and others associated with scientific work are included in the King's Birthday honours list:

Baron: Sir Alfred Webb-Johnson, president of the Royal College of Surgeons.

K.B.E.: Sir Hector Hetherington, principal and vice-chancellor of the University of Glasgow; Acting Air Commdre. Frank Whittle.

Knights Bachelor: A. Leigh B. Ashton, director of the Victoria and Albert Museum; Dr. A. H. Gardiner, the well-known Egyptologist; Dr. C. R. Harington, director of the National Institute for Medical Research; Prof. C. N. Hinshelwood, Dr. Lee's professor of chemistry, University of Oxford; J. D. G. Medley, vice-chancellor of the University of Melbourne.

C.B.: H. M. Garner, principal director, scientific research (air), Ministry of Supply; N. H. Kinnear, director of the British Museum (Natural History); O. Thornycroft, director of aeronautical and engineering research, Admiralty.

C.M.G.: W. N. Allan, recently director of irrigation, Sudan Government; Dr. P. Stocks, chief statistician (med.), General Register Office; Dr. H. H. Storey, secretary of the Colonial Agricultural Research Committee.

C.B.E.: Prof. W. E. Agar, lately professor of zoology, University of Melbourne; H. H. B. Allan, director of the Division of Botany, Plant Research Bureau, New Zealand; Prof. J. H. Biggart, professor of pathology and dean of the Faculty of Medicine, Queen's University, Belfast; Dr. H. W. Cremer, president of the Institution of Chemical Engineers; Mrs. Maud E. Cunnington, for services to archæology; Prof. A. Findlay, emeritus professor of chemistry, University of Aberdeen, for services to chemistry; B. E. Frayling, Colonial Mines Service, lately chief inspector of mines, Nigeria; Lieut.-Colonel W. French, superintendent of the Technological Department, City and Guilds of London Institute; Dr. A. A. Griffiths, research engineer, Rolls-Royce, Ltd.; W. F. Higgins, superintendent of the Physics Division, National Physical Laboratory; Prof. W. R. Jones, emeritus professor of mining geology, University of London (Imperial College of Science and Technology), for services to the Board of Trade; C. Kershaw, director of British Optical and Precision Engineers, Ltd., for services to the production of optical instruments; Dr. A. King, chief scientific liaison officer, Office of the Lord President of the Council; Prof. H. A. D. Neville, lately professor of agricultural chemistry, University of Reading; Miss Margery Perham, reader in Colonial administration, University of Oxford; Prof. J. Ritchie, professor of natural history, University of Edinburgh; Dr. H. V. Taylor, lately senior education and advisory officer, Ministry of Agriculture; S. G. Taylor, director of irrigation, Ceylon.

Sir James Chadwick, F.R.S.

Sir James Chadwick has been pre-elected Master of Gonville and Caius College, Cambridge, of which he has been a fellow and more lately an honorary fellow. Sir James began his scientific work under Rutherford in Manchester; after studying in the University of Berlin he was interned in Germany during the First World War, and there continued his scientific researches. When Rutherford moved to Manchester, Chadwick joined him and took part in Rutherford's classical researches on the disintegration of elements by α-particles. With Bieler and later with Rutherford he studied the scattering of α-particles by hydrogen and heavier nuclei, and from these experiments determined the law of force around atomic nuclei. He became assistant director of research under Rutherford at Cambridge, and as such was responsible for the training of Rutherford's young research students and for the satisfaction of their modest needs. Many nuclear physicists will remember the attic of the Cavendish equipped with ancient vacuum pumps, gold-leaf electroscopes and the simple apparatus for counting α-particles which was then the main tool of nuclear research. The discovery of the neutron in 1932, followed by the photodisintegration of the deuteron (with Goldhaber) and the creation of electron pairs by γ-rays (with Blackett and Occhialini), marked the peak of Chadwick's experimental work. In 1935 he was appointed Lyon Jones professor of physics in the University of Liverpool, and at once embarked on the construction of a 36-in. cyclotron, completing this just prior to the Second World War.

On the outbreak of war, Chadwick took up the study of nuclear chain reactions based on the fission of uranium, and with Frisch and Peierls informed the Government in the spring of 1940 that an atomic bomb could probably be produced if sufficient U235 were concentrated. Further studies of nuclear constants in Liverpool and Cambridge confirmed this view. At the end of 1943, Chadwick was largely instrumental in restoring the collaboration with the United States in atomic energy which was severed in 1941. He recruited a small but powerful British team to work in Los Alamos and Berkeley, and took a leading part with Dr. Mackenzie in establishing the Canadian Atomic Energy Project at Chalk River. Since the War he has served on the Scientific and Technical Committee of the United Nations Atomic Energy Commission. On his return to Liverpool he initiated the construction of a cyclotron to produce 300 MeV. protons. Chadwick's pupils in nuclear physics are distributed over the whole world. They will regret his severance from active experimental work but will all wish him well in the tasks which lie ahead.

Dr. E. D. Merrill

Dr. E. D. Merrill retires from the Arnold professorship of botany, Harvard University, at the end of June. As professor emeritus he is to remain in the house on the margin of the Arnold Arboretum that has been his as director of the Arboretum where, granted good health such as all his many friends wish him, he will enjoy the facilities for botanical study that have been so considerably shaped by him. Under him the inflow of material, living and dried, into the Garden and Herbarium from eastern Asia, Malaysia and the Pacific has been tremendous; and it is well that he should take a large part in elaborating it. Born on October 15, 1876, Elmer Drew Merrill passed in 1899 from College into the United States Department of Agriculture. In the Department he was selected (1902) for the appointment of government botanist in the Philippine Islands and went out to Manila, one of a few men chosen to start a science service towards which at that time there was nothing but a budgetary appropriation. It was soon evident that his methods were direct and effective. Botanical teaching was added (1912) to his work, and in 1918 the administration of the Bureau of Science. In 1923 the University of California sought and secured his service as dean of the College of Agriculture, where it was his duty to draw into order State-wide organisations that were growing up too loosely knit. In 1930 New York induced him to cross the continent to take the post of director-in-chief of the New York Botanic Garden. Institutions in the United States such as it, depend much on private generosity, and in bad times suffer checks to their activities: it is so in New York, and he had the years of the great depression to combat. It need be no secret that his successes in adjustment led to an invitation to move to Boston (1935) into a post made for him with the title of administrator of the Botanical Collections of the Harvard University and director of the Arnold Arboretum. The collections that passed under him had some likeness to the miscellany he set in order in California, at least in diversity. The University has rearranged these responsibilities; and his last, the teaching of advanced students in methods of research, passes elsewhere. He is now free to devote his time to botanical research.

Dr. L. H. Bailey

Dr. Liberty Hyde Bailey, eminent administrator, botanist, horticulturist and author, attained his ninetieth birthday on March 15. On this date he was actually on Arruba Island in the West Indies on one of his annual palm-hunting expeditions to tropical America. He was signally honoured on his return to Ithaca, New York, in May by a complimentary dinner sponsored by Cornell University, with which institution he has been associated for the past sixty years. On this occasion, with approximately two hundred guests in attendance from various parts of the United States, the speakers extolled Dr. Bailey's eminent services to Cornell University, to agricultural instruction, research and extension, to botany, to horticulture, and to the humanities. The outstanding feature of the evening was Dr. Bailey's informal address, which dealt with his early experiences and some of his later achievements. Tall, straight, speaking extemporaneously and without notes, it was indeed an inspiration to all who heard him on this occasion.

Bailey's career has been an extraordinary one. His father was an early settler in what a century ago was the wilderness of Michigan, and the son's early years were thus associated with the primitive conditions of pioneer life. Following his graduation from college in 1882 he served for several years as assistant to the eminent American botanist Asa Gray at Harvard University, and it was this experience, plus his personal interests, which determined his future career. He is the last living associate of Gray, who, in turn, was a frequent visitor to London and was the outstanding American exponent of the Darwinian hypothesis. Even when because of his special qualifications Bailey was selected as dean and director of agriculture at Cornell University in 1903, he accepted appointment only on the condition that he would be permitted to resign from administrative work at the end of ten years. He retired from academic work as emeritus professor of agriculture in 1921, but this did not mean quiescence on his part. His energies have since that date been devoted to his special botanical and horticultural interests, including the botany of cultivated beauty, an intensive study of North American *Rubus*, and a long-continued investigation of the palms and their classification; and it is this special interest in palms that has inspired him to make trip after trip to remote parts of Mexico, the West Indies and South America in recent years, with future ones already planned. In 1937 he presented his home, his library and his large herbarium to Cornell University, this unit being designated as "The Bailey Hortorium"; and of this he is still the director. His honours have been very numerous, for the value of his achievements has been recognized all over the world. Among these is foreign membership of the Linnean Society and honorary membership of the Royal Horticultural Society of London.

U.S. National Museum: Dr. A. Remington Kellogg

Dr. A. Remington Kellogg has been appointed director of the United States National Museum. Dr. Kellogg has been curator of mammals in the Smithsonian Institution for the past seven years. He is one of the leading experts on whales and whale-like animals. His doctorate thesis, dealing with cetacean palæontology, attempted to trace the ancestry of the earth's largest animals from their land origins. He has served as delegate for the United States on several international congresses dealing with whale conservation and had a leading part in the establishment of the great Antarctic whale sanctuary set up by international agreement. The National Museum, which Dr. Kellogg now will administer, is the largest of the Federal bureaux administered by the Smithsonian Institution. It is the storehouse of what now is probably the most extensive systematized natural history collections in the world, ranging from elephants to fossil insects. It contains large ethnological and historical collections and valuable series in the field of mechanics and inventions.

University of Cambridge

General Smuts was installed as chancellor of the University of Cambridge on June 10. He then conferred honorary degrees on the following, among others: Mr. Winston Churchill; Sir Stafford Cripps; Sir Hector Hetherington, principal and vice-chancellor of the University of Glasgow; Mr. Charles Seymour, president of Yale University; Mr. J. F. Cameron, master of Gonville and Caius College, Cambridge; Sir Hugh Lett, president of the British Medical Association; Sir Wilson Jameson, chief medical officer of the Ministries of Health and Education; Sir Richard Livingstone, vice-chancellor of the University of Oxford; Sir Robert Robinson, president of the Royal Society; Sir Paul Fildes, of the Medical Research Council; and Mr. Arnold Toynbee, director of studies in the Royal Institute of International Affairs.

National Federation of Educational Film Groups

The National Federation of Educational Film Groups recently held its first annual conference in King's College, University of London. Membership of the Federation now amounts to thirty-three groups, representing more than 2,500 teachers. The Federation aims at co-ordinating and assisting the activities of groups of teachers specifically organised to encourage and develop the use of visual aids to teaching, at stimulating the formation and development of such groups, and at collating and analysing the views and knowledge of those experienced in visual methods. Its work includes the development of a library of film strips and charts, the publication of surveys of existing films under specific subject headings, and the organisation of courses for the study of visual aids. The main resolution debated at the conference welcomed the plans of the National Committee for Visual Aids and reaffirmed the support of the Federation in the Committee's task of promoting the wider adoption of visual methods in education. Attention was directed to the need for breaking the "vicious circle of supply and demand in materials", to the importance of reducing production costs, and to the necessity of ensuring that units making educational films were at all times assisted by clear directives. It was decided to establish a fact-finding committee which should report to the Council of the Federation on matters concerning the production and distribution of visual aids.

The conference was also made the occasion of an exhibition housed in the large hall of King's College and designed to provide a wide selection of equipment and materials for visual presentation. Makers, producers and distributors of visual material and projectors had been invited to exhibit and nearly fifty had accepted. The range of exhibits included film and film strip projectors, film strips, wall charts and accessories. An ingenious arrangement of stalls made for the convenience of both exhibitors and visitors and allowed demonstrations to proceed simultaneously. A useful guide-book was available containing details of exhibits and available sources of supply. A nearby room was used for full-length projection of educational films and film strips. The exhibition was well attended, and stall-holders were kept busy throughout the day. The idea of combining conference and exhibition was certainly a happy one, and the organisers are to be congratulated on this and on the excellence of their arrangements.

Chemical Engineering and Fuel Technology at the University of Durham

Commencing in October 1948, King's College, Newcastle upon Tyne, will offer a two-year postgraduate course in chemical engineering leading to the degree of master of science in chemical engineering of the University of Durham. The course will be available to graduates in mechanical engineering or to those who possess some equivalent degree or qualification. The opportunity has been taken to link with chemical engineering the teaching of fuel technology, which has hitherto been carried out by individual departments as required. The main subjects of study during the course will include, in the field of chemical engineering, materials of construction and the design of chemical plant, the flow of fluids and the transfer of heat and matter and the various unit operations. The fuel technology course will include the fuel industries, steam, power and industrial gases. A series of lectures will also be given on the economic, legal, health and safety aspects of chemical engineering. Practical work will be carried out in a new fuel technology laboratory and in a new chemical engineering laboratory which will house a number of small-scale plants.

British Museum (Natural History)

THE first three sections of a new exhibition in the central hall of the British Museum (Natural History), South Kensington, dealing with viruses and virus diseases have been opened. The exhibition has been planned in collaboration with Dr. K. M. Smith, of the Plant Virus Research Station, Cambridge. The effects are shown of virus infection in animals and plants (for example, foot-and-mouth disease, and tobacco mosaic disease), and modes of virus transmission both by direct contact and by means of insects are illustrated. Further exhibits in this series which are in preparation will cover the subjects of virus 'carriers' and the study of viruses in the laboratory.

Colonial Service Appointments

THE following appointments in the Colonial Service have been announced: W. Finalayson, assistant conservator of forests, Tanganyika; R. R. H. Horsley, inspector of mines, Malaya; R. L. Rodda, inspector of mines, Nigeria; A. H. Foster, veterinary officer, Malaya; J. P. Knowles, veterinary officer, Nigeria; A. D. Swan, assistant meteorologist, West Africa; E. G. Waller, temporary agricultural survey officer (cocoa), Gold Coast; G. W. Anderson (agricultural officer, Kenya), agricultural officer, Zanzibar; W. J. Badcock (senior agricultural officer, British Solomon Islands Protectorate), chief soil conservation officer, Nyasaland; R. K. Kerkham (agricultural officer, Uganda), senior agricultural officer, Uganda; T. Y. Watson (senior agricultural officer, Kenya), deputy director of agriculture, Uganda; F. B. Wilson (agricultural officer, Zanzibar), agricultural officer, Kenya; A. C. Brooks (senior chemist, Singapore), chief chemist, Federation of Malaya; A. W. Burtt (senior chemist, Federation of Malaya), chief chemist, Singapore; W. D. Raymond (Government chemist, Medical Department, Tanganyika), Government chemist, Tanganyika.

Browne Research Fund of the Royal Society

THE Council of the Royal Society is prepared to consider applications for financial assistance from research workers at marine biological stations or universities in Great Britain who desire to visit Bermuda for periods of three to six months to carry out a specific programme of work at the Bermuda Biological Station. Applicants should state the nature of the research proposed, the sum required, including an estimate of any loss of salary incurred during absence, and give the names of not more than two referees who will support the application. In accordance with Mr. Browne's bequest, preference will be given to those who propose to work on purely scientific problems. As a guide to possible applicants, the special interest of the present director of the Station, Dr. D. E. S. Brown, lies in the effects of high-pressure on the physics and chemistry of biological functions, for which the deep water off Bermuda provides unique facilities. Applications for grants required for the period ending April 1949 should reach the Assistant Secretary, Royal Society, Burlington House, London, W.1, not later than September 1, 1948.

Announcements

SIR ALEXANDER FLEMING, professor of bacteriology in the University of London, has been awarded the Grand Cross of Alfonso X, and has also received an honorary degree from the University of Madrid.

THE following appointments in the University of Oxford have been announced: Mr. D. G. Champernowne, reader in statistics in the University, to be professor of statistics; Prof. J. Jewkes, Stanley Jevons professor of political economy in the University of Manchester, to be professor of economic organisation.

M. ROBERT COURRIER has been appointed 'secrétaire perpétuel' for the physical sciences of the Paris Academy of Sciences in succession to the late Prof. Alfred Lacroix (see p. 962 of this issue of *Nature*).

THE Commissioners of the Exhibition of 1851 announce the following awards of senior studentships for 1948: D. H. Perkins, for research in nuclear physics at the Imperial College of Science and Technology, London; J. H. Westcott, for research in electrical engineering at the Imperial College of Science and Technology, London; A. R. Pinder, for research in organic chemistry in the University of Oxford; N. Reynolds, for research in botany at University College, Cardiff. The awards are of the value of £500 a year (exclusive of allowances), and are tenable for two or three years.

A CONFERENCE of the British Society for Research on Ageing will be held on July 7, from 11 a.m. to 6 p.m., at the Royal Society of Medicine, London. Papers will be read by Sir Frederick Bartlett and Prof. E. C. Dodds, and Drs. F. Bourliere, L. Cosin, F. Denz, E. Geiringer, V. Korenchevsky and O. Olbrich. The Conference will be open to all who are interested in gerontology.

THE Trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee in London, they have made the following awards for research in blood diseases, with special reference to leukæmia, at the places mentioned, in the academic year beginning on October 1, 1948: *Grants for research expenses and assistance*: Dr. Marcel C. Bessis (Paris); Dr. Jörgen Bichel (Aarhus); Dr. Pierre Cazal (Montpellier); Dr. Johannes Clemmesen (Copenhagen); Dr. Peter A. Gorer (London); Dr. Andrew Kelemen (Szeged); Dr. Edith Paterson (Manchester); Prof. Edoardo Storti (Pavia). *Scholarships* (*for whole-time or part-time research*): Dr. Simon Iversen (Copenhagen); Dr. Claus F. M. Plum (Copenhagen); Dr. Guido H. R. Tötterman (Helsinki).

A CONGRESS of Genetics was held at the Centro di Genetica del Consiglio Nazionale delle Ricerche in Pavia during April 2–4. We understand that the *Proceedings* will be published shortly; a monograph on the biology of about a hundred species of insects more or less suitable for genetical researches is also being planned.

Anomalous Effects in Ionospheric Absorption

In current methods of vertical sounding of the ionosphere by radio waves, two relationships are usually experimentally determined, namely, (1) the value of the equivalent height of reflexion (h') as a function of radio frequency (f); and (2) the value of the attenuation ($\log \rho$) as a function of frequency f. (Here ρ is the experimental value of the overall ionospheric reflexion coefficient.)

Using the vertical incidence (h', f) relation, which expresses the refractive properties of the ionosphere, it has been found possible to predict, with fair accuracy, the refractive influence of the ionosphere on waves obliquely incident on it. In this case the relations between any two of the three variables, h', f and i_0 (where i_0 is the angle of incidence of the radio beams on the ionosphere), may be predicted when the other quantity is assigned a constant value. There has, however, been no such corresponding success in predicting the absorptive behaviour of the ionosphere for obliquely incident waves, using the ($\log \rho, f$) relation as determined for the conditions $i_0 = 0$. Indeed, under certain conditions, which we describe below, a most flagrant disagreement is found between the predictions of oblique-incidence absorption based on commonly accepted radio theories and the results found in practice.

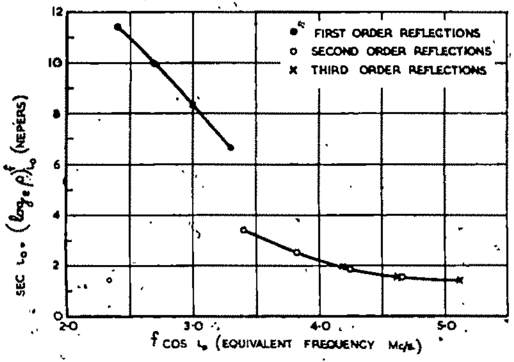

Fig. 1

Some years ago, Martyn[1] introduced the useful conception of equivalent frequency into theoretical relationships between vertical-incidence and oblique-incidence phenomena, by showing how it was possible to relate in simple fashion the absorption of a wave of frequency f, impinging on the ionosphere at an angle of incidence i_0, with the vertical incidence absorption of its equivalent frequency, defined as $f \cos i_0$. Martyn's absorption equivalence theorem can be written as follows:

$$\sec i_0 \, [\log \rho]^{f}_{i_0} = [\log \rho]^{f \cos i_0}_{0}. \qquad (1)$$

In some radio pulse experiments conducted during the War between Burghead (Scotland) and Slough, over a distance of 715 km., measurements were made of $\log \rho$, using F-layer reflexions, for different values of f and i_0. To test how far these results support the relation (1), we have plotted, in Fig. 1, $[\log \rho]^{f}_{i_0} \sec i_0$ as a function of $f \cos i_0$. If the results satisfied relation (1), we should expect all the points to lie on a single curve. The diagram shows, however, that, although second-order and third-order echoes are indicated by points which lie on the same curve, the points indicating first-order (and thus the most obliquely incident) reflexions do not also lie on that curve. There seems indicated, in fact, either abnormally heavy attenuation of the singly reflected echoes or else abnormally weak absorption on the higher orders. That the anomaly is the former rather than the latter is, however, shown in the following table, where the actual attenuations for the singly reflected F-layer echoes are compared with the values calculated from vertical-incidence absorption data using Martyn's relation (1), given above.

PREDICTED AND EXPERIMENTAL VALUES OF IONOSPHERIC ABSORPTION AT OBLIQUE-INCIDENCE (ORDINARY-RAY COMPONENTS)

Date	Frequency (Mc./s.)	Observed absorption of first-order F-echoes (nepers)	Predicted absorption (nepers), based on Martyn's theorem and vertical incidence data
Dec. 27, 1944	4·3	2·82	1·29
	4·53	2·42	1·11
	4·78	2·06	0·96
	4·9	1·94	0·91
	5·2	1·90	0·84
	5·42	1·22	0·85
	5·65	1·43	0·85
Dec. 28, 1944	4·3	1·49	0·71
	4·52	1·48	0·79
	4·78	1·69	0·74
	5·42	1·83	0·96
	5·65	2·24	0·76

We have detected a similar large discrepancy between the ionospheric absorption observed over a long-distance communication circuit and that predicted from normal incidence absorption data.

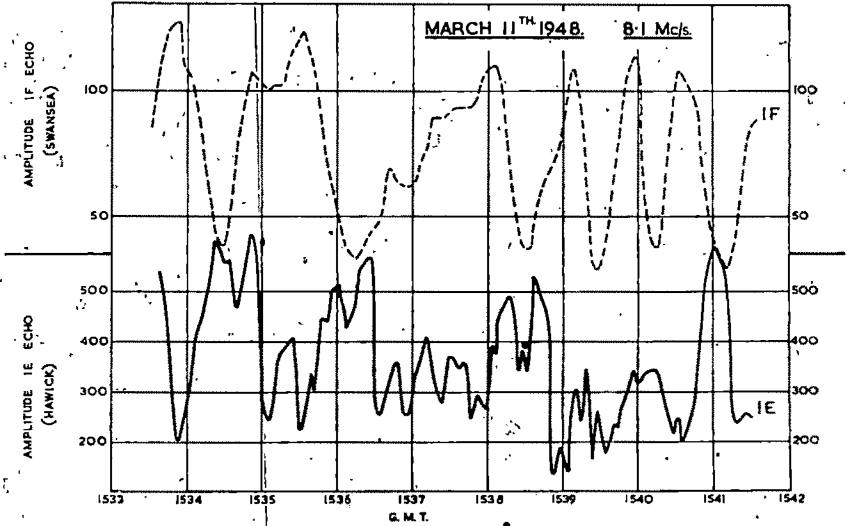

Fig 2.

It is therefore clear that there is some attenuating agency operative which is neglected in the physical basis underlying the formulation of Martyn's relation. Now Martyn assumed that the process of attenuation was that brought about by the ionospheric electron collisions with the air molecules. His theorem is also limited in applicability to conditions in which the frequency of such electronic collisions is small compared with the angular frequency of the radio waves and in which the influence of the earth's magnetic field on absorption can be neglected. In attempting to trace the source of the discrepancy described above, we have attempted to generalize the theorem so as to widen its applicability in the above two respects, but have found that the modified expressions do not account for the anomaly.

We have thus been forced to conclude that there is an agency of attenuation operative which is additional to that caused by electronic collisional friction. In this connexion we may note that under the conditions of our experiment, and indeed in many practical cases too, the frequencies used were only slightly in excess of the oblique-incidence critical frequency for the *E*-layer, which the radio waves traverse on their journey to and from the *F*-layer. This fact has led us to suspect that the additional attenuating agency might be the scattering or partial reflexion of the waves by abnormal or sporadic *E*-layer ionization, the effect of which, as can easily be shown theoretically, is not predicted quantitatively by Martyn's theorem.

To test this hypothesis, experiments have recently been carried out to see whether there is any correlation between sporadic *E*-layer reflexions and the attenuation of waves which pass through that layer. From a pulse sender situated near Frazerburgh, Scotland, *F*-layer first-order echo amplitudes were observed at Swansea over a distance of 685 km. It was estimated that the radio waves on their upward journey to the *F*-layer would pass through the scattering and partially reflecting centres of the *E*-layer at a distance of about 130 km. from the sender. Simultaneous observations of the amplitude of sporadic *E*-layer echoes were therefore made at double this distance, namely, at Hawick. In Fig. 2 are shown plotted some temporal variations of signal amplitudes observed at the two sites, from which it is seen that, when the strength of sporadic *E*-layer echoes at Hawick increases, the waves reflected by the *F*-layer suffer substantial attenuation. It is therefore clear that deviation by sporadic *E*-layer ionization may sometimes have an important influence on the amplitude of waves reflected by the *F*-layer, and we interpret these results as supporting our conclusion concerning the identification of the origin of the discrepancy mentioned above.

A fuller account of these and other absorption measurements and their interpretation will be published elsewhere. The work has been carried out as part of the programme of the Radio Research Board of the Department of Scientific and Industrial Research.

Theory of Superconductivity

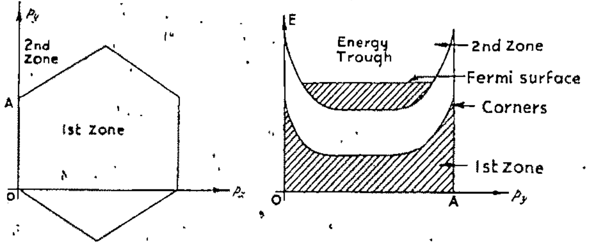
It is a controversial question whether the phenomenon of superconductivity is merely a consequence of the quantum theory of interaction among electrons or whether it depends on the specific crystal structures. The first point of view is taken in Heisenberg's theory[1]. However, it can be shown by general reasoning that if the ionic forces between ions and electrons are disregarded, all states with a total current different from zero will have higher energy than those without. Moreover, there is a strict isomorphic correspondence between all states without current and all states with a given current. Consequently the free energy of the states with a current cannot be the smallest at any temperature. Secondly, Heisenberg's theory predicts the existence of superconductivity in all metals, including the alkali metals; yet so far experimental evidence does not confirm this.

On the other hand, we have found an empirical rule that indicates a correlation between superconductivity and lattice structure; namely, that those metals are superconductive for which the Fermi surface, supposed to be a sphere, lies in very close proximity to one set of the corners formed by the boundary planes of a Brillouin zone. The following table shows the different ratios of the radius of the Fermi surface and the distance from the origin to those corners, for most of the superconductive elements and for some of the non-superconductive elements.

Lattice type	Superconductive elements		Non-superconductive elements	
Body-centred cubic	V, Ta, βZr	1·03 and 0·98	Li, Na, K, Rb, Cs,	$\leqslant$0·75
Face-centred cubic	Al, βLa, βTl, Th, Pb(?)	1·008	Ca, Sr	$\leqslant$0·88
			Au, Ag, Cu	$\leqslant$0·7
Close packed hexagonal	Zn	0·927		
	Cd	0·925		
	αTl	1·10		
	αLa	1·098		

This table encourages the view that a correct theory of superconductivity should be based on the ionic forces. It is known that these ionic forces have predominant influence on the behaviour of the electrons, if the Fermi surface is close to the boundary planes of the Brillouin zone. Now if the Fermi surface nearly circumscribes a complete Brillouin zone, it is certain that the circumscribed zone is full and the next zone is partially filled. The accompanying figure gives a rough sketch of the aspect of a plane (E, p_y), where E is the energy and p_y the component of the momentum along one side of the polygon representing a cross-section through a Brillouin zone. The energy surface $E(\mathbf{p})$ has a discontinuity along this plane which is largest at the corners O, A, and small between them. Hence if interaction of electrons is neglected, the first zone is filled up to the corners, while the second zone is partially filled at the bottom of the energy trough.

If now interaction of electrons is taken into account, the electrons near the corners of the first zone may



migrate into the trough of the second zone, or vice versa. One has to investigate which of these possibilities happens, and whether the symmetry in momentum space of the arrangement is not so disturbed as to produce a mean momentum (current). Among these correlation forces the Coulomb exchange force between electrons with parallel spins is the largest, as, according to the calculation of Wigner and Seitz[2] for the dissociation energy of sodium and lithium, the exchange energy is nearly four times as large as the correlation energy between electrons of antiparallel spins. For simplicity consider a unit volume of metal. We can now estimate the energy required to pick out n electrons from a filled corner and redistribute them in the trough on top of the Fermi surface. Let $\mathbf{p}_0$ be the momentum corresponding to the highest energy-level in the corner. Then the energy of a single electron with momentum $\mathbf{p}$ in the neighbourhood of $\mathbf{p}_0$ is

$$E(\mathbf{p}) = E(\mathbf{p}_0) - \frac{1}{2m^*}(\mathbf{p}_0 - \mathbf{p})^2, \qquad (1)$$

where m^* is the effective mass, generally small for the electrons near the top of a broad band[3]. For the assembly of electrons one has to consider further the interaction described above. Let ω_0 be the number of corners which can be assumed to lie symmetrically in the momentum space, and let $n_1, n_2, \ldots n_{\omega_0}$ be the numbers of electrons removed from the corresponding corners. The calculation gives for the total change of energy

$$\Delta E = \sum_i n_i \left\{ \varepsilon_0 - \frac{3}{4}e^2\left(\frac{3}{4\pi}\right)^{1/3} n_i^{1/3} + \frac{3}{5}\left(\frac{3}{4\pi}\right)^{2/3} \frac{h^2}{2m^*} n_i^{2/3} \right\} + \frac{h^2}{8\pi m}\left(\frac{\pi}{3n_0}\right)^{1/3}\left(\sum_i n_i\right)^2, \qquad (2)$$

where n_0 is the mean density of electrons. The constant ε_0 and the last term with $n_i^{2/3}$ in the bracket come from the kinetic energy (1), the middle term with $n_i^{2/3}$ from the exchange energy, and the last term with $(\Sigma n_i)^2$ from the filling up the free Fermi surface.

From (2) one calculates the minimum value of ΔE, varying the occupation numbers $n_1 \ldots n_{\omega_0}$. The result shows that it is possible to have a state of lowest energy such that, out of ω_0 corners, only $\omega (< \omega_0)$ are 'excited', which means that a number of electrons n ($\sim 10^{-5}\, n_0 \sim 10^{18}$) are removed from each corner and redistributed on the free Fermi surface, while the remaining $\omega_0 - \omega$ corners are intact. The magnitude of $n \sim 10^{-5} n_0$ obtained is easily understood by observing that the minimum of ΔE must be near that value of n where the two terms with $n_i^{2/3}$ and $n_i^{1/3}$ in the bracket cancel, that is, where (using the Bohr radius $r_1 = \hbar^2/me^2$).

$$l \equiv n^{-1/3} = \frac{8\pi^2}{5}\left(\frac{3}{4\pi}\right)^{1/3} \frac{m}{m^*}\left(\frac{\hbar^2}{me^2}\right) = 9{\cdot}8\,\frac{m}{m^*} r_1. \qquad (3)$$

Now it is known that $m^* = \frac{1}{5}m$, hence $l \sim 50\,r_1$, and $n = (50\,r_1)^{-3} \sim 10^{-5}\,n_0$, as the size of the cell is of order $r_1{}^3$.

An asymmetric occupation of the corners represents a state with a resultant momentum and therefore with a spontaneous current.

One has now to determine the thermodynamical properties of this state. The free energy can be calculated by taking account of the thermal agitation of electrons transferred to the free Fermi surface, their thermal energy being equal to $\frac{\omega}{\omega_0}\frac{2\pi^3 m}{3h^2}\left(\frac{3n_0}{\pi}\right)^{1/3} k^2T^2$. The transition temperature T_c is defined by $\omega = \omega_0$, because when this state is reached the asymmetry and hence superconductivity disappear.

Thus one finds

$$T_c = \sqrt{\frac{3}{8}}\,\frac{n\omega_0 h^2}{\pi^2 km}\left(\frac{\pi}{3n_0}\right)^{1/3} \qquad (4)$$

and $T_c \sim 1°$ K., if for n the value 10^{18}, previously obtained is substituted. The change of specific heat on passing the transition temperature T_c is found to be approximately

$$\Delta C = \frac{4\pi^3 mk^2}{3h^2}\left(\frac{3n_0}{\pi}\right)^{1/3} T\left(\frac{3T^2}{T_c{}^2} - 1\right). \qquad (5)$$

The formula agrees with one obtained empirically by Kok[4].

We have made a preliminary investigation of the electrodynamics of superconductivity and found that the length $l = n^{-1/3}$ represents the depth of penetration of a magnetic field in a superconductor as introduced by London. The theoretical order of magnitude $l \sim 10^{-6}$ cm. agrees with the requirement of measurements. The detailed theory will be developed by one of us (K. C. C.).

An Anomaly in Electromagnetic Theory

IN a paper which is being issued as a scientific report by the Defence Research Board, Ottawa, and which may be published elsewhere later, I have shown that it is impossible by means of the Maxwell–Lorentz theory of electromagnetism to obtain a reasonable or consistent result for the following problem.

If an electric charge in uniform motion passes near a stationary closed conducting loop, the magnetic field of the charge will link the loop, and hence an E.M.F. and current should be induced in the loop as the charge passes by. If, however, the loop moves and the charge is stationary, with the same relative motion as before, Maxwell–Lorentz theory gives zero-induced E.M.F., and it is shown that this result is not affected by the magnetic effects of the charges induced by the stationary charge on the surface of the moving coil.

The induction of a current in the first case, however, is inconsistent with the principle of the conservation of energy, since although the coil experiences the correct electromagnetic reactive force, the electromagnetic force on the moving charge is perpendicular to its direction of motion, and hence no work is required to maintain its prescribed motion.

The electromagnetic theory of Ritz is shown to give equal finite E.M.F.s in the two cases, but again the principle of conservation of energy is violated.

There appear to be only two possible ways of escape from the energy dilemma. Either no E.M.F.

can be induced or the electromagnetic force on the charge must have a component opposing its motion. The first possibility seems scarcely credible, since the facts of electromagnetic induction by the relative motion of two constant-current circuits, coupled with the electronic theory of conduction, present convincing evidence that an E.M.F. *should* be induced in this problem. The second possibility is contrary to the usual interpretation of Ampère's experiment, in which he found that a current-carrying wire could not be moved longitudinally by a neighbouring magnet or current. It is shown, however, that since the *current-path* in the movable wire in Ampère's experiment could not move, it is not possible to find out by means of such an experiment whether an electrically neutral current-element, or a single moving charge, can experience a longitudinal magnetic force or not. The existence of a small longitudinal force is not, therefore, inconsistent with experiment, and seems to provide the only possible solution of this anomaly of energy conversion.

It appears that the problem is amenable to experimental test, and a practicable arrangement for the apparatus is described. It is shown that the effects of electrostatically induced charges on the coil should not obscure the main effect.

It would appear that only a relative-velocity theory of the type developed in a preliminary way by Ritz can give a reasonable result for this problem. The description of the behaviour of high-speed charged particles by Ritz's theory, however, is different from that given by classical relativistic electrodynamics. For example, Bucherer's classical experiment is explained by Ritz without any variation of the mass of the electron. The problem, therefore, seems to be of considerable fundamental significance to physical science. The special theory of relativity does not appear to resolve it, since relativistic transformations confirm that a magnetic field, and hence an E.M.F., should exist in one case but not in the other.

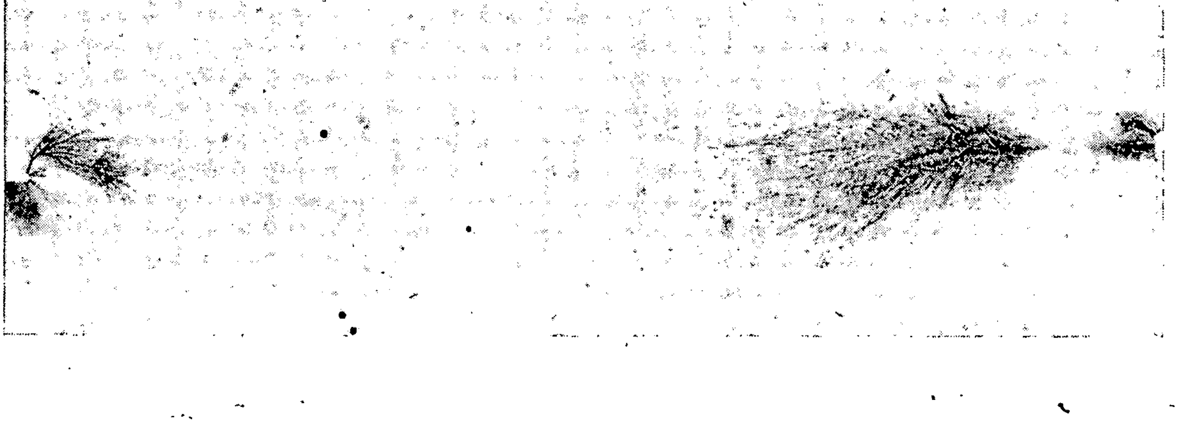
Development of the Spark Discharge

THE development of the spark discharge has been studied with the aid of the rotating camera[1,2,3] in a manner similar to Schonland's studies of the lightning discharge, and the leader-stroke mechanism which he first described has been shown to precede in similar manner the main spark discharge in air at atmospheric pressure. Schonland[4] suspected that the stepped leader discharge was not advancing into wholly un-ionized or virgin air, and suggested that it travelled along a pre-existing ionized path, the path of a 'pilot streamer', which probably moved from cloud to ground with the effective velocity of the stepped leader process, say, 10^7 cm./sec. He failed to record this pilot streamer—if it exists—photographically.

In the laboratory I found[2] it very difficult to photograph all that the eye could see of the discharge process between a point electrode at, say, one million volts to ground, and a plane earthed electrode, even with the aid of a quartz-rock salt lens of wide aperture. This fact was not sufficiently emphasized in Allibone and Meek's[3] account of the process, so that Bruce[5] has suggested that the leader-stroke might be formed from a diffuse glow discharge of the kind which is plainly visible in some of our rotating camera photographs and described as a "shower of discharge".

There is no doubt that a faint and very extensive corona discharge precedes the concentrated bright streamer which is readily photographed: I studied this corona carefully in complete darkness in 1931, though I did not describe it when the branching of the negative spark discharge was described[6]. In 1938 [2] I published the best photograph (Fig. 2 of that paper) that I had succeeded in taking in 1931: the corona discharge was seen to extend over the whole of a 4-ft. gap between electrodes, although the concentrated bright streamer (now called the leader-stroke) never exceeded 25 per cent of the gap length. This corona discharge and the leader-stroke can be seen quite easily if precautions are taken to prevent complete spark-over, which is so blinding to the eye; the use of a spark gap having the requisite time-lag placed in parallel with the gap under observation is the customary means of achieving this, and, by careful control, the leader-stroke in the gap under observation can be chopped at various periods of its development. Normal photographic techniques, however, do not show how this leader develops from the corona discharge.

I have recently studied this corona/leader-stroke transition, with the aid of the Lichtenberg figure technique I described in 1938 [2] in conjunction with the chopped-spark technique to prevent the recording of the main-stroke which otherwise would completely obliterate the photographic record of the corona discharge. One of the photographs obtained is shown. It records the corona at the negative high-voltage point electrode (– 500 kV.) and at the grounded point electrode; the bright streamers from both electrodes (negative and positive leader-strokes)



are both evident. Many observations have first been made without the photographic paper bridging the gap, and it can be stated beyond doubt that the presence of the paper makes very little difference, if any, to the appearance of the discharge. Details of the corona playing over the surface of the emulsion are far superior to any details which can be photographed through a lens: indeed, with a lens, practically only the leader-strokes would have been recorded.

I am certain now that the missing 'pilot streamer' is corona discharge similar to that shown in the photograph; that the leader-stroke develops behind this faint corona and is in the nature of a 'core' to the voluminous corona shower, a trunk and a few main branches in relation to the tree with its innumerable small branches and twigs. Why this is stepped in the lightning flash is still a matter for study; that it is stepped in the laboratory may be due mainly to the circuit; the terminal voltage may be diminished by the current taken by the leader-stroke, but the present experiments do not elucidate this, so further experiments are in progress.

I wish to thank Dr. F. J. Miranda and Mr. F. E. Chivers for assistance in these experiments, and the Metropolitan-Vickers Electrical Co., Ltd., for the loan of the portable impulse generator: also Dr. W. A. Berry, of Messrs. Ilford, Ltd., for the photographic papers selected for use.

Note added in proof. The printed record is inferior to the photographic record, which shows the corona bridging the gap.

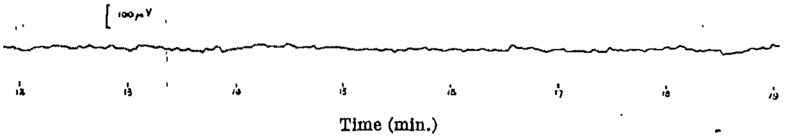
Low-Frequency Noise from Thermionic Valves Working under Amplifying Conditions

ALTHOUGH there is a great deal of information concerning the noise produced by thermionic valves at radio frequencies, there do not appear to have been published data for the low-frequency noise intensity they produce under amplifying conditions. It has long been known that the noise intensity increases as the frequency to which the observational system is tuned is diminished, and a theory of the origin of this so-called 'flicker' noise has been given by Schottky[1] and modified by Macfarlane[2]. One of us (E. J. H.) has made measurements of valve noise and found that the intensity of the low-frequency noise varies approximately inversely as frequency in the range 10–1,000 c./s. At 1,000 c./s. it was not observable above the 'shot' noise. If expressed as an equivalent fluctuation E.M.F. at the grid, the low-frequency noise was remarkably constant from valve to valve.

Those observations, however, do not suffice to allow calculation of the performance of a direct-coupled amplifier covering a band of zero to (say) 1,000 cycles, as it is the very low-frequency fluctuations which set a limit to the useful amplification. It is, of course, difficult to distinguish between fluctuations arising in the valves, and those resulting from irregularities in the external circuits; but the figure for the low-frequency noise which we have obtained using a particularly well-stabilized direct-coupled amplifier sets an upper limit to the valve noise integrated over the band zero—1,000 cycles. A balanced system using 6*J*6 valves with input shorted produces fluctuations having a maximum amplitude equivalent to 20 μV. (peak to peak) when observed on an oscilloscope over a period of several seconds. Using a moving coil pen recorder it has been possible to obtain an accurate record of the low-frequency fluctuations over a period of 30 min. (see record above). The maximum peak-to-peak fluctuation in the record was about 60 μV. One result of the concentration of the noise of the zero frequency end of the spectrum is that extending the band-width to cover 0–5,000 cycles does not appreciably increase the total valve noise.



PORTION OF THE PEN RECORDER TRACE COVERING THE 12TH TO THE 18TH MINUTE OF A 30-MIN. RECORDING.

ORDINATE: E.M.F. EQUIVALENT AT INPUT TERMINALS TO THE VALVE UNBALANCE.

When a 2·2 megohm resistance was connected across the input the thermal agitation noise (6 μV. r.m.s. for a 1,000-cycle band-width) of the resistance could be seen to increase the mean noise-level (observed in a short period) by some 50 per cent.

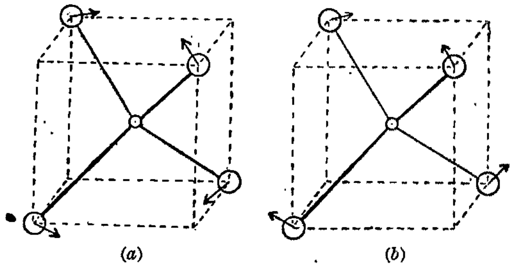
A Correlation between Molecular Vibrations and Bond-forming Orbitals

IN a recent letter, Heath and Linnett[1] suggested for the treatment of molecular vibrations a new force field, the orbital valency force field. This is based more closely on modern ideas of directed valency than is the simple valency force field. We decided to test the orbital valency force field on methane, which is a convenient molecule to use, since all the deuterium-substituted methanes have been studied[2]. The first result obtained was that the original theory failed in this case. In particular, for CH_4 and CD_4, it was found that, to explain the frequencies of the doubly degenerate bending vibrations, a bending constant (k_H/r^2) of $1\cdot35 \times 10^5$ dynes/cm. was required, whereas the triply degenerate bending vibrations needed a constant of $0\cdot86 \times 10^5$ dynes/cm. Bending motions which are members of these two degenerate sets are shown in the accompanying drawings.

The relative values of these two bending constants indicate that it is easier to bend the molecule in the sense of Fig. *b* than in the sense of Fig. *a*.



(a) THE DOUBLY DEGENERATE, AND (b) THE TRIPLY DEGENERATE BENDING VIBRATIONS OF METHANE

The bond-forming orbitals of the carbon atom in methane are sp^3 hybridized giving four equal bonds[3]. It can be shown that the hybridization of these orbitals can be changed so that the orbitals alter their directions in a manner similar to the vibration shown in Fig. *b*, but that they cannot change their hybridization to alter their directions in a manner similar to Fig. *a*. It appears, therefore, that the bending shown in Fig. *b* is easier than that shown in Fig. *a*, because the bond-forming orbitals of the carbon atom can, by changing their hybridization, partially follow the hydrogen atoms during vibration *b*, but not during vibration *a*.

This means that we need two constants to describe the bending: (i) an orbital bending constant measuring the force tending to restore the hydrogen atom when it is moved away from the line along which the carbon bond-forming orbital has its maximum value (k_H); (*b*) an orbital following constant measuring the increase of energy when the bond-forming orbitals are distorted by change of hybridization (k_β).

If $\Delta\alpha$ is the bending of the four C—H directions from their original orientation at a certain stage of the vibration in Fig. *b*, and $\Delta\beta$ is the angle through which the orbitals have followed this movement, we may write for the potential energy

$$2V = 4k_H\,(\Delta\alpha - \Delta\beta)^2 + k_\beta\,\Delta\beta^2,$$

since $(\Delta\alpha - \Delta\beta)$ is the angle between the distorted C—H direction and the new direction in which the orbital has its maximum value.

The value of $\Delta\beta$ will be that which makes the energy a minimum. By differentiating V with respect to $\Delta\beta$ and equating the differential to zero, we can eliminate $\Delta\beta$:

$$2V = \frac{4k_H k_\beta}{4k_H + k\beta}\,\Delta\alpha^2.$$

When k_β is infinite, there is no orbital following, and the above expression for the potential energy reduces to the simple orbital valency force field expression:

$$2V = 4k_H\,\Delta\alpha^2.$$

But if k_β is not infinite, $k_H k_\beta/(4k_H + k_\beta)$ is less than k_H, that is, distortion is easier.

This type of force field has been applied to CH_4, CH_3D, CH_2D_2, CHD_3 and CD_4 using three constants: valency stretching constant $k_2 = 4{\cdot}95 \times 10^5$, $k_H/r^2 = 1{\cdot}362 \times 10^5$ and $k_\beta/r^2 = 12{\cdot}98 \times 10^5$ dynes/cm. With these three constants it is possible to explain the fourteen stretching vibration frequencies with an average error of 0·81 per cent and a maximum error of 2·15 per cent, and to account for the fifteen bending vibration frequencies with an average error of 1·19 per cent and a maximum of 2·44 per cent.

The merit of this force field is that, not only does it account for the twenty-nine vibration frequencies of these molecules, but also it accords well with the wave-mechanical conception of the bond-forming orbitals of the carbon atom. It introduces a relation between the distortion of the bonding orbitals and the molecular vibrations, which means that information regarding these distortions can be obtained from molecular vibration frequencies. It is hoped to apply similar ideas to other molecules.

Electrical Resistivity of Alkali Metals Below 20° K.

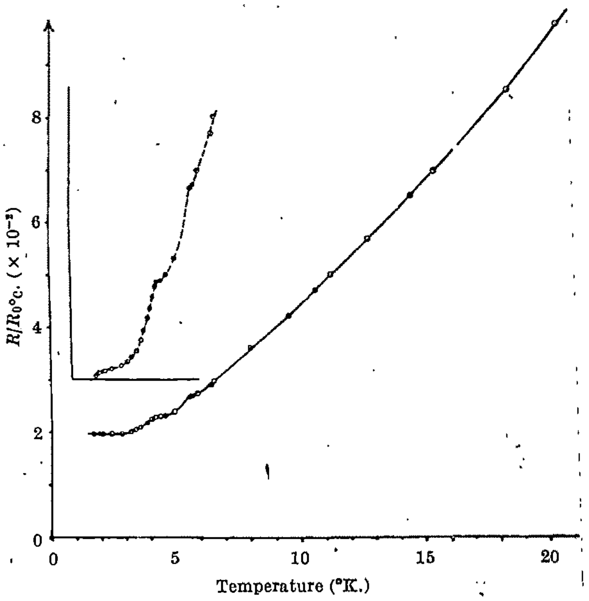
THE change of the electrical resistivity of pure metals at temperatures below 20° K. is of considerable theoretical importance. While there is available a great body of experimental data at the temperatures of liquid hydrogen and helium, only one set of experiments[1] exists in the intervening region, which covers a 5 : 1 ratio in absolute temperature. Since for most metals the resistance becomes largely independent of temperature below 4° K., this region (between 4° and 20° K.) is crucial for determining the law of resistance variation with temperature. We have now modified a previously described helium cryostat[2] working on the Simon expansion principle for continuous work between 1·5° and 20° K., temperatures being determined by a gas thermometer, and the electrical resistance with a sensitive galvanometer amplifier[3].

	Lithium	Sodium	Potassium	Rubidium	Cæsium
n	4·52	4·85	3·2	2	(1·4)
Θ	350	200	160	80	(50)
n_Θ	5·0	4·9	4·9	3·5	(2·4)
$\frac{n_\Theta - n}{n_\Theta}$	0·1	0·01	0·35	0·43	(0·42)
$\frac{\sigma}{M\Theta^2}\cdot V^{1/3}$	30·4	70·1	54·8	53·9	57·8

The whole alkali metal group has now been surveyed, and a short summary of the results is given in the accompanying table. Subtracting the temperature-independent residual resistance, in accordance with Matthiessen's rule, n represents the apparent power variation with temperature deduced from logarithmic plots of the data. According to Bloch's theory[4], n should be 5: the deviation of the lattice vibrations from the Debye T^3 law has, however, to be taken into account. Using Grüneisen's formula[5] in conjunction with the Debye characteristic temperatures, Θ, a corrected value of the theoretical power variation n_Θ (appropriate to each metal) can be derived for the region concerned. It appears that agreement between observation and theory only obtains in the case of sodium. An estimate of the degree of deviation $(n_\Theta - n)/n_\Theta$ is given in the fourth row of the table.

Bloch's theory (and Grüneisen's formula) will only be expected to be valid where the Fermi surface is a sphere in *k*-space as is generally assumed for the monovalent metals. Our results seem to indicate that, except for sodium, the Fermi surfaces of the alkali metals are distorted. A critical survey of other physical data on the alkali metals—for example, the reduced conductivity at 0° C., $\frac{\sigma}{A\Theta^2}.V^{1/3}$—appears to strengthen this assumption. Distortion of the Fermi surface in the case of lithium may possibly be due to insufficient screening of the valency electron; in the case of the higher alkalis, to the effect of electrons from the lower shells.

The parameters for cæsium appear in parentheses because, besides the general deviation from the expected power law, two definite 'kinks' in the resistance curve appear in the neighbourhood of 4° K. (see graph), leaving a degree of uncertainty in the residual resistance, etc.



ELECTRICAL RESISTANCE OF CÆSIUM AT LOW TEMPERATURES. *Inset.* RESISTANCE ON MAGNIFIED SCALE; TEMPERATURE SCALE UNCHANGED

Similar anomalies between 9° K. and 14° K. were observed with potassium. The obvious explanation of an experimental error in the temperature measurement was obviated by various control experiments. In the case of cæsium the suspicion that the anomalies might be caused by inclusion of mercury, superconductive below 4·1° K., was removed by chemical and spectrographic analysis. Furthermore, the high purity of the samples, which were obtained by redistillation, is indicated by the relatively low residual resistance. Another batch of cæsium from the same source showed a distinctive kink in the resistance curve at ~ 10° K., while the anomaly at ~ 4° K. was much less marked. Preliminary investigations on the variation of resistance in transverse magnetic fields (up to ~ 4 kG.) at 4° K. and 2° K. also yielded curves with analogous anomalies. In this connexion it is of interest to note that Meissner and Voigt[6] from their measured values on cæsium at 4° K. and 20° K. suspect a discontinuity in the resistance-temperature curve in the intervening range.

On the strength of the evidence before us, we cannot suggest an adequate explanation for these anomalies. The different behaviour of our two samples of cæsium suggests some sort of dependency on structure; it is worth remembering that superconductivity, too, exhibits structure-dependent features which are particularly strong in the less well-investigated metals such as vanadium, titanium and uranium. It appears possible, further, that these anomalies in the electrical resistance may be related to small anomalies in the specific heat, such as were observed in beryllium by Cristescu and Simon[7] and in sodium by Pickard and Simon[8].

A detailed account of this research will be published elsewhere. The investigation on the alkali metals is intended as the first part of a survey of the low-temperature resistivity of pure metals in general, and work is now in progress on the second column of the Periodic Table.

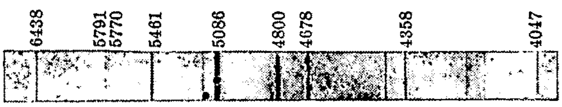
A Simple Way of Photographing Spectra

Recently, I have been photographing spectra in their natural colours with 35 mm. Dufaycolor film. The spectra were produced by a single 60° flint prism. 35 mm. film is used in a camera of 5 cm. focal length and, if this camera had been used by itself, the spectra would have been much too short. I therefore tried to photograph them through the telescope of the spectrometer; that is, the telescope object glass and eyepiece were left in position and the camera placed immediately after the eyepiece. The telescope had a magnification of about 11 times, so this would increase the angular extent of the spectrum from 2½° to 27½°. I found that the field of view of the spectrometer eyepiece was too narrow, but on substituting the eyepiece of a prismatic field-glass which took in a cone of semivertical angle 128′ instead of the previous 53′, the experiment succeeded; the visible spectrum covered the full breadth of the film and was in perfect focus from end to end.

The method is naturally not restricted to colour film, and the accompanying photograph shows what can be done by it with the Ilford Special Rapid Panchromatic plate and an exposure of three minutes. In this case a 3¼ in. × 2½ in. plate was used length-



ways and the spectrum occupied the full length of the plate. The wave-lengths are marked in angstroms. Any camera will do. The eye-ring of the telescope is only 2½ mm. in diameter and about 9 mm. out from the end of the telescope, so a lens working at $F/16$ is ample. The spectrum is focused with the telescope, and the camera is focused on infinity; so it does not require a focusing arrangement. Not only is the spectrum in focus from end to end of the plate, but also the latter gives the theoretical value for the resolving power all over it. The spectrum is that of the cadmium mercury arc.

It is almost impossible to discover anything new in optics nowadays, and someone is probably using this method at the present time. But I have seen no reference to it anywhere, and I have never seen or heard of a spectrometer with a wide-angle eyepiece. So I think it worth while to direct attention to the possibilities of the method here. It replaces the spectrograph for many purposes and opens up an interesting new field to experiment.

Some hints may be added. If a crown glass prism is used, the spectrum extends to 3500 A. But the ultra-violet portion is out of focus, the object glasses not being corrected for this region. Several spectra may be obtained on the same plate by tilting the camera or (not so good) by tilting the prism table. It is not possible to use the snapshot shutter of the camera for quantitative work; there are no sources bright enough. If the wide-angle eyepiece is used without the camera, but with a very wide slit, the arrangement is very suitable for projecting spectra and making them visible to a class; in this case the screen should be about three feet from the eyepiece.

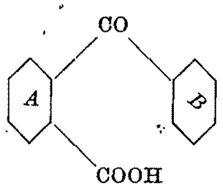
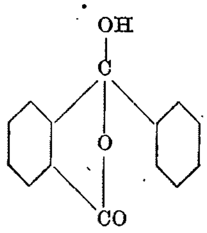
Differential Effect of 2-Benzoylbenzoic Acid and its Derivatives upon Plant Species

AT the time of the discovery of the selective herbicidal activity of (i) the substituted phenoxyacetic acids[1,2] and (ii) the arylcarbamic esters[3,4], many other chemical types were examined, and 2-benzoylbenzoic acid and its derivatives received considerable attention because of their marked biological activity[5]. The investigation of this type was at the time abandoned because of the superior promise of the phenoxyacetic acid derivatives as agents for the practical control of crop weeds. It is felt desirable, nevertheless, to place our observations on record, for it is our view that as the study of the subject develops, increasing numbers of different types of chemicals will be found to display selective herbicidal action, and the recording of data will contribute to the ultimate understanding of the relationships between chemical constitution and herbicidal effect.

2-Benzoylbenzoic acid and many of its derivatives are readily accessible chemicals since they are employed in the synthesis of anthraquinone derivatives. Since auxin-like activity, as well as the selective herbicidal effect which it is believed may depend on this biochemical function, is found in aromatic and heterocyclic carboxylic acids in which the carboxylic acid group is attached through a linking group to a cyclic nucleus, 2-benzoylbenzoic acid appeared to be a suitable choice for examination. This substance is considered to have the structure I, but it gives rise to isomeric pairs of esters; the normal esters of configuration corresponding to I, and the pseudo esters corresponding to structure II[6,7].



I



II

The benzoylbenzoic acid derivatives studied are all described in the literature and were prepared by conventional methods, being characterized by their melting points, which in all cases corresponded with the recorded data. The esters were of the normal configuration and the pseudo esters were not examined. The preparation of 2 : 4 : 5-trichlorophenylacetic acid has been described by Sexton[8].

The biological methods employed were described by Templeman and Sexton[2] and consisted of a laboratory germination test at a concentration of 200 parts per million of test substance in water, and a soil test. The acids were examined as sodium salts and the esters in dispersed form, prepared by dissolving them in a little alcohol and pouring into a large bulk of water. In the soil test, oats and charlock were sown together in boxes in the open, the chemical being applied in dry form diluted with sand at a rate equivalent to 25 lb. per acre. α-Naphthylacetic acid was used as a standard of comparison.

In accordance with the method previously used, the activities of the various compounds against charlock are recorded relative to that of α-naphthylacetic acid, as follows:

Class A: Substances of greater activity than α-naphthylacetic acid.
2 : 4 : 5-Trichlorophenylacetic acid.

Class B: Substances approximately equal in activity to α-naphthylacetic acid.
2-(4′-Chlorobenzoyl) benzoic acid.

Class C: Substances of some activity but less active than α-naphthylacetic acid.
2-Benzoylbenzoic acid.
2-(3′ : 4′-Dichlorobenzoyl) benzoic acid.
2-(4′-Chloro-3′-nitrobenzoyl) benzoic acid.
2-(α-Naphthoyl) benzoic acid.

Class D: Substances of low or doubtful activity or inactive.
Methyl 2-benzoylbenzoate.
Ethyl 2-benzoylbenzoate.
2-Benzoyl-4-(5)-chlorobenzoic acid.
2-Benzoyl-4 : 5-dichlorobenzoic acid.
2-Benzoyl-3 : 4 : 5 : 6-tetrachlorobenzoic acid.
2-(2′ : 5′-Dichlorobenzoyl) 3 : 6-dichlorobenzoic acid.
2-(2′ : 5′-Dichlorobenzoyl) 3 : 4 : 5 : 6-tetrachlorobenzoic acid (damage to oats).
2-(4′-Chloro-3′-aminobenzoyl) benzoic acid.
2-(4′-Methylbenzoyl) benzoic acid.
2-(4′-Chloro-α-naphthoyl) benzoic acid.
Phenylacetic acid.

In the seed germination test, it is known that the susceptibility of charlock and the resistance of oats is a characteristic response to β-indolylacetic acid, α-naphthylacetic acid and the substituted phenoxyacetic acids. Further, as all these chemical types produce characteristic effects such as epinastic responses on mature plants, it would appear that the mechanism of growth-inhibition of charlock may be concerned with hormonal defunction. 2 : 4 : 5-Trichlorophenylacetic acid also fits into this picture, for an epinastic response of oat coleoptiles on emergence was observed, and it is a powerful inhibitor of charlock seed germination. Preliminary experiments have indicated that a response in the Went pea test is given by one of the more active members of the benzoylbenzoic acid series, namely, 2-(3′ : 4′-dichlorobenzoyl) benzoic acid ; but the generality of the parallelism between the effect on charlock and auxin-like activity cannot be asserted until a more comprehensive examination has been made of these and other compounds.

Veldstra[9] has put forward the hypothesis that the biochemical effects of auxin-like substances have a physical basis, and that activity is found in substances in which an acidic group is bound to a cyclic nucleus in such a way that the direction of the negative pole lies at an angle (ideally, at right angles) to the plane of the ring. The activity of the benzoylbenzoic acids is not inconsistent with this hypothesis when it is borne in mind that the benzoyl radical can rotate freely about the bond uniting it to the benzoic acid nucleus (*A* in formula I), so that there is the possibility of the —COOH group projecting at an angle to the plane of the benzene ring (*B*) of the benzoyl group. It is perhaps significant that the weighting of this particular ring (*B*) alone by appropriately disposed chlorine atoms does not decrease the activity. Indeed, the activity was definitely increased in one case. A similar weighting of the ring *A* with which the —COOH group is coplanar reduced the activity.

An Improved Method for the Assay of Toxicity of Arsenicals

Since the pioneer work of Durham, Gaddum and Marchal[1] on toxicity tests for arsenicals, comparisons have been carried out using the method of quantal responses. The statistical implications of this method have been the subject of a considerable volume of work[2-4]. No amount of perfection of analysis can, however, compensate for the inherent shortcomings of the method.

In a quantal response assay, each animal can contribute only a positive or a negative reading (in this case death or survival) to the total information obtained. In the event of the death of an animal, there is no indication as to whether the dose given was the exact minimum individual lethal dose for that animal, or whether, in fact, it was considerably in excess of this amount. Thus the method is usually wasteful of information when a continuous variate such as survival-time can be employed instead, and only where no such continuous variate can be used in an easily measurable form is recourse to quantal response methods necessary.

In the case of the arsenicals there seems to be no such difficulty. Using the survival-time as the continuous variate, it has been found possible to perform an assay with increased speed, accuracy, and economy in animals. Where the survival-time for each animal is used in this way, a definite numerical estimate of the toxicity of the drug for that particular animal has been obtained, and, provided that a linear dose-response relationship can be employed, it is naturally to be expected that more information will be gained per animal used in the test.

With this principle in mind a series of experiments was carried out. The same standard preparation of 'Neoarsphenamine' was used throughout, 'Neoarsphenamine' being one of the most widely used of all the arsenicals. The experiments were so designed that the methods of quantal responses and direct measurement of survival-times could be compared. The dose range in the latter case was chosen to ensure that all the animals treated should die, and that the longest period of survival should not exceed 10 hours. It was found possible to establish a linear relationship between dose of drug and mean survival-time when a logarithmic transformation of both was used. Statistical analysis of the results shows the graded response method to be accurate and unbiased. The accompanying table shows the calculated approximate limits of error for both types of assay, and for varying numbers of animals in the test. It is assumed in each case that the slope of the dose-response line is accurately known.

Method of assay	Minimum approximate percentage limits of error ($P = 0{\cdot}05$)		
	$n = 10$	$n = 20$	$n = 40$
Quantal response	77·5–129·0	83·4–119·7	88·1–113·6
Graded response	86·0–116·2	90·3–110·7	93·2–107·3

The limits of error for the graded response assay are thus about half as wide as those for the quantal response assay, and the accuracy of the estimation of potency is about four times as great. Trial assays have been performed on this basis with satisfactory results.

Although for the practical purpose of safeguarding against the issue for sale of highly toxic material the standard quantal response assay method may be satisfactory, it is hoped that this alternative method will be of value in those cases where a greater degree of accuracy is desirable. Work on these lines is still in progress and will be published in more detail at a later date.

Grateful acknowledgment is due to Dr. C. W. Emmens for his advice throughout the course of this work.

Reaction of β-Naphthol with *l*-α- and *l*-β-Phellandrene

SOME years ago, Goodway and West[1] reported that low yields of the maleic anhydride adduct corresponding to α-phellandrene were obtainable from β-phellandrene, and it was considered probable that the *l*-α-phellandrene adduct isolated was derived by the thermal decomposition of the primary resinous material obtained from the *l*-β-phellandrene.

In attempts to obtain another derivative characteristic for β-phellandrene, we have studied the reaction of this terpene with β-naphthol and obtained a product which melted at 137–138°, whereas Salfeld[2] obtained a product melting at 139–140° from a sample of α-phellandrene of which the constants were not recorded. The *l*-β-phellandrene utilized in our experiments was derived from Canada balsam oil which has been shown to be free from the α-isomeride[3], and the *l*-α-phellandrene used for comparison was prepared by fractionation from the oil of *Eucalyptus dives*. From the melting point, mixed melting point, and optical rotation of the reaction products of the two terpenes with β-naphthol, the adducts appear to be identical. Further evidence of the identity and structure of the adducts is being sought, and in view of the fact that the infra-red absorption spectra[4] of α- and β-phellandrene offer the best possibility of distinguishing readily between the two terpenes, it is hoped that it may be possible to establish the mechanism of the reaction of the β-isomeride with β-naphthol.

Inhibition of Hexosediphosphatase by Sulphhydryl Reagents and by Ascorbic Acid

DURING the course of an investigation of the action of vitamin K and its biological antagonists (dicoumarol, salicylate) on various phosphatases, details of which will be published elsewhere, it was observed that liver hexosediphosphatase[1] exhibited a much greater sensitivity towards quinones than did the other phosphatases. Purified bone phosphomonoesterase[2], for example, required a concentration of $10^{-3} M$ benzoquinone for complete inactivation, whereas $10^{-5} M$ benzoquinone was sufficient completely to inhibit the hexosediphosphatase.

It is well known that enzymes the activity of which is dependent on free —SH groups are inhibited by quinones in very low concentrations, and it has been suggested that the antibiotic activity of quinones is a result of this effect[3]. With the exception of some pyrophosphatases and transphosphorylases, the phosphatases, the activity of which is probably dependent on free amino-groups[4], are, on the other hand, not affected by —SH reagents[5]. The comparatively high quinone sensitivity of hexosediphosphatase, however, led us to examine the behaviour of this enzyme towards other substances which are known to react with thiol groups.

Our experiments show that hexosediphosphatase is inhibited by iodoacetate, by phenyl mercuric nitrate and by alloxan. Cysteine, which itself inhibits in sufficiently high concentration but strongly activates at lower concentrations, completely reverses the iodoacetate and phenyl mercuric nitrate inhibitions and partly reverses that by alloxan. Thus inhibition by iodoacetate ($10^{-2} M$) or by alloxan ($2{\cdot}5 \times 10^{-3} M$) is 40 per cent. Cysteine ($10^{-3} M$) reactivates the iodoacetate-inhibited enzyme 100 per cent and the alloxan-inhibited enzyme 37 per cent (that is, inhibition is reduced from 40 to 25 per cent). Inhibition by alloxan ($5 \times 10^{-3} M$) is complete and there is no reactivation by cysteine. Phenyl mercuric nitrate ($10^{-4} M$) inhibits 100 per cent, with complete reactivation by cysteine ($2{\cdot}5 \times 10^{-4} M$). Cysteine ($5 \times 10^{-4} M$ and $1 \times 10^{-3} M$) alone activates 98 and 96 per cent respectively, while an increase in concentration to $5 \times 10^{-3} M$ results in complete inactivation.

The hexosediphosphatase used was prepared as described by Gomori[1] and was free from non-specific phosphatase activity. Mixtures (10·0 ml.) of the enzyme solution (0·1 ml.), borate buffer (2·0 ml.), $0{\cdot}05 M$ magnesium sulphate (2·0 ml.), sodium hexosediphosphate solution (2·0 ml. ≡ 0·2 mgm. phosphorus) and inhibitor were incubated for 30 min. at 37° and *p*H 9·1 in separate tubes, and the inorganic phosphate in each was determined colorimetrically. The quantity of enzyme used was such that half the substrate was hydrolysed in the controls (that is, no inhibitor) during the period of incubation. No phosphate was liberated in the absence of enzyme. When iodoacetate was used, it was incubated with the diluted enzyme-magnesium-buffer mixture for 15 min. before addition of the substrate and of cysteine.

Experiments with ascorbic acid, which was expected to activate the enzyme by virtue of its reducing properties, showed it to be a very powerful inhibitor. Concentrations below $5 \times 10^{-7} M$ resulted in slight activation (up to 5 per cent), but concentrations greater than $10^{-6} M$ inhibited, with complete inactivation in the presence of $2 \times 10^{-3} M$ ascorbic acid. This inactivation by ascorbic acid is undoubtedly due to competition with the hexosediphosphate, as indicated by the results of experiments with varied substrate concentrations. Results of a typical experiment are given in the accompanying table.

Ascorbic acid, molar concentration × 10^4	Substrate solution (ml.)	Inorganic phosphorus (μgm.)	Inhibition (per cent)
0	1·5	573	0
2·5	1·5	371	35
5	1·5	317	45
5	3·0	245	32
10	3·0	200	45
0	3·0	360	0

These results also confirm Gomori's observation that the substrate itself inhibits the enzyme as the concentration is raised and, for this reason, the amount of enzyme solution used was increased to 0·15 ml. in the above experiment.

Inhibition of β-malt amylase by ascorbic acid and related compounds was attributed by Hanes[6] to the presence in the molecule of the di-enol grouping. Giri[7] has shown that several plant and animal phosphatases, which were not affected by ascorbic acid, were inhibited by an ascorbic acid-copper complex. Our experiments demonstrate that ascorbic acid may compete for an enzyme with a substrate which it resembles in ring structure. The possibility that ascorbic acid may compete with hexose diphosphate for other enzymes such as aldolase or with other furanose-sugar phosphates, and thereby influence the course of carbohydrate or nucleotide metabolism, seems to us to be worthy of further investigation.

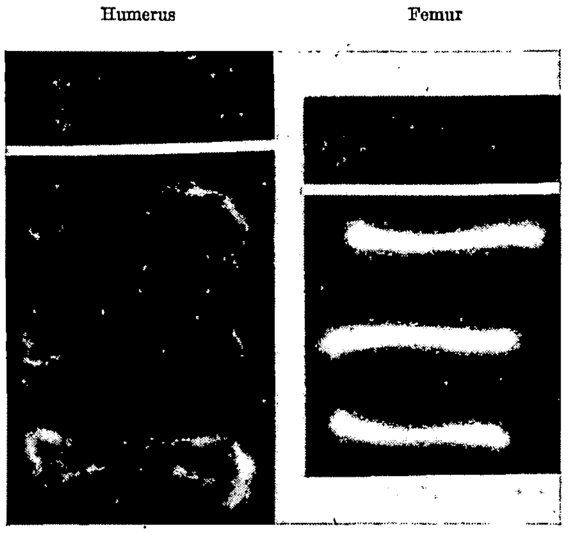
Influence of Folliculin on Bone Metabolism, Studied by Means of Radiophosphorus, $^{32}_{15}P$

IN these experiments, all pigeons received daily 0·15 mgm. phosphorus labelled with radiophosphorus (subcutaneously) and 80 mgm. phosphorus provided by a normal diet (principally Indian corn). In addition, all pigeons, except control birds, received daily 0·25 mgm. œstradiol dipropionate ('Ovocycline P' Ciba, intramuscularly). The radiophosphorus was prepared by irradiations of phosphorus with deuterons produced by the cyclotron of the Laboratoire de Chimie Nucléaire of Paris (Prof. F. Joliot-Curie).



UPPER PHOTOGRAPHS: CONTROLS
LOWER THREE PHOTOGRAPHS: EFFECT OF FOLLICULIN

The right-hand autoradiograph was taken after a 20-day treatment; it shows the femur of a control pigeon and those of three pigeons submitted to folliculin administration. The new medullary bone is very rich in injected radiophosphorus; the quantity of the latter present in the control femoral diaphysis, however, is clearly perceptible. It appears, indeed, according to the determination of radioactivity by means of a Geiger–Müller counter, that the new medullary bone contains on an average seven or eight times more injected radiophosphorus than the femur of a control pigeon. As it can be seen from the left-hand autoradiograph, the mineral metabolism of bones such as the humerus, the medullary cavities of which are not filled with folliculinic bone, is, however, accelerated under the influence of œstradiol; radiophosphorus takes the place of phosphorus in the diaphysis as well as in the epiphysis to a greater extent in the treated pigeon than in untreated ones.

By calculating the amount of ordinary phosphorus from food and of phosphorus from parenteral administration (radiophosphorus), by measuring the rate of elimination of both forms of phosphorus and the quantity of these two elements present in bone, we have found that nearly half the phosphorus present in new medullary bone does not come directly from phosphorus fed or injected, but from phosphorus already stored in the skeleton. The proportion of labelled phosphorus observed at the end of a 20-day experiment shows that nearly 13·1 per cent of bone phosphorus (femur) has been renewed in a pigeon receiving folliculin, but only 1·7 per cent in the controls.

Sublittoral Seaweed Survey: Relationship of Algal Growth and Depth

DURING the current survey of seaweed of the sublittoral zone of Scotland, very extensive sampling has been carried out. The samples are taken by means of a calibrated spring grab which closes by trigger action on touching bottom. The seaweed samples are weighed, species noted and also the depths from which they are obtained.

A survey of the sublittoral zone around the Argyllshire coast[1] has shown that a straight-line relationship exists between the mean density (d_t) of the total number of sampling operations and the depth:

$$d_t = 5{\cdot}48 - 0{\cdot}34 f,$$

where d_t is density (kgm./m.^{2}) and f is depth (metres). *Laminaria Cloustoni* is the dominant species. No large brown algæ were found below nine fathoms.

With the data obtained from the survey of Argyllshire, it was estimated that more than one million tons of seaweed was likely to be found growing in Orkney waters. Surveys to date indicate this figure to be conservative.

The results of surveys in Scapa Flow, Orkney (800 acres), have again shown that a straight-line relationship occurs between mean density and depth:

$$d_t = 6{\cdot}95 - 0{\cdot}41 f.$$

Laminaria Cloustoni is the dominant species, and the density of seaweed growth is greater than on the coast of Argyll. No very strong tidal streams occur in either of these two above areas.

Two separate and extensive surveys have been carried out on opposite sides of Wide Firth, Orkney, namely, the Bay of Firth (1,500 acres) and around the island of Shapinsay (3,000 acres). *Laminaria saccharina* is dominant in both areas.

Unlike the formula above, it is found that the square root of the mean density of total sampling operations divided by the percentage cover is approximately a constant:

$$\frac{\sqrt{d_t}}{C} = k;$$

where d_t is mean density of total sampling operations, and C is cover (number of samples with weed expressed as a percentage of total number of sampling operations).

For Bay of Firth

$$\frac{\sqrt{d_t}}{C} = 3{\cdot}04 + 0{\cdot}10f\ (\pm 4\%)\ \text{1–6 fathoms L.W.}$$

For Shapinsay

$$\frac{\sqrt{d_t}}{C} = 4{\cdot}06 - 0{\cdot}07f\ (\pm 4\%)\ \text{1–7 fathoms L.W.}$$

Very strong tidal streams are associated with Wide Firth.

A recently completed survey of Sanday Sound (8,300 acres), involving more than 2,500 sampling operations, showed a similar formula to that found for Bay of Firth and Shapinsay. *Laminaria saccharina* is the dominant species in these two areas, whereas *Laminaria Cloustoni* is dominant in Sanday Sound as in Scapa Flow.

The value for Sanday Sound is

$$\frac{\sqrt{d_t}}{C} = 3{\cdot}05 - 0{\cdot}02f\ (\pm 5\%)\ \text{1–10 fathoms L.W.}$$

$$\text{Now } d_t = d_w C.$$

$$\therefore\ \frac{\sqrt{d_t}}{C} = \sqrt{\frac{d_w}{C}},$$

$$\text{so that } d_w \propto C,$$

where d_t is mean density of total sampling operations, d_w is mean density of sampling operations which brought up weed, and C is cover expressed as percentage.

It follows, therefore, for Bay of Firth, Shapinsay coast and Sanday Sound, where very strong tides occur, that seaweed density (d_w) is directly proportional to the cover of the whole area, and in Scapa Flow and around the Argyllshire coast, where strong tidal streams do not occur, the mean density (d_t) of the whole area is inversely proportional to depth.

In the former cases $d_t \propto C^2$ and in the latter case $d_t \propto 1/f$.

Variations from the constant, $\frac{\sqrt{d_t}}{C}$, are due to small differences in the weights of individual plants.

Sampling has shown that at 4 and 5 fathoms in the Bay of Firth and Shapinsay, the *number* of plants and not their individual weights is chiefly responsible for great differences in mean density. The number of plants is found to be exactly proportional to the cover of the whole of the survey areas:

	% Cover at 4 and 5 fathoms	No. of plants/unit area
Bay of Firth	41	2·5
Shapinsay	77	4·7

The most interesting points brought out in these surveys of the sublittoral zone is that seaweed density of the larger brown algæ and the depth at which they grow conform to two simple mathematical laws: (1) that where strong tidal forces occur, the density of algæ is proportional to the weed coverage of the *whole* area. This can be accounted for by reproduction and spore dispersal; (2) that where strong tidal forces do not occur, the density is inversely proportional to the depth at which the algæ grow.

Full details will be published later.

The above surveys are part of the programme of research of the Scottish Seaweed Research Association.

Transplantation of Fertilized Rabbit Ova: the Effect on Viability of Age, *in vitro* Storage Period, and Storage Temperature

IN 1890 and 1897, Heape[1] demonstrated the unimportance of somatic tissue to the germ cells by his successful transplantation of rabbit ova to a uterine foster mother. In 1934, Pincus and Enzmann[2] obtained normal young by transplanting rabbit ova fertilized or cultured *in vitro*. Recently[3], I reported normal development of ova stored at low temperature, and an optimal temperature for storage. I now have data on the probability of normal development after various treatments.

Ova were obtained from superovulated rabbits[4], and kept in undiluted rabbit serum. 25 hours after insemination they were recovered from the oviducts, and were mostly in the two-cell stage. If recovered after 72 hours they were mostly morulæ, some in the oviducts and some in the uterus. At 96 hours they were nearly all in the uterus, some being at the blastocyst stage. The ova were either transplanted fresh, or stored at 0° C. (slow cooling over a five-hour period) or at 10° C., or cultured at 38° C. (subcultured daily), before transplantation.

Recipient does were caused to ovulate by gonadotrophin injection. In one series of experiments, fresh 25-hour ova were transplanted to the uterus. In all the other experiments (most of which are summarized in the table), irrespective of the period of culture or storage, ova one day old at recovery were transplanted to the oviducts of does injected one day before the operation, while ova three and four days old were put into the uteri of does injected three and four days previously. Ova were placed in the oviducts through the fimbria, and into the uterus by puncturing its wall with a pipette containing the ova. Each host doe received five to twenty ova, the average number being increased with the length of time the ova were kept *in vitro*.

Most of the pregnant recipient does were killed 25–28 days after the operation. Some fœtal degeneration is normal in the rabbit[5], and young dead *in utero* (about 6 per cent of all young) were taken to represent normal development. The sex of live young, the number of maternal placentæ (ova implanted but failing to develop) and number of fœtal placentæ (resorption of embryo or fœtus) were recorded.

TRANSPLANTATION OF FERTILIZED RABBIT OVA: THE EFFECT ON VIABILITY OF AGE, *in vitro* STORAGE PERIOD, AND STORAGE TEMPERATURE

Storage temperature (°C)	Storage time (hr.)	Age of ova before storage (days)	Number of				Young as percentage of ova transplanted
			Ova transplanted	Recipient does	Does pregnant	Normal young	
30	1–2	1	239	24	21	130	54
		3	132	11	5	41	31
		4	89	9	5	21	24

	48	1	153	9	6	41	27

The results (see table) show: (1) that the younger the ova transplanted, the better is their chance of normal development. This is seen clearly in the case of ova freshly transplanted (1–2 hours storage time) and is also shown with ova stored 24 hours at 10° C. In the latter series the percentages of ova developing normally in the does actually pregnant were respectively 70, 44 and 22 with ova recovered at one, three and four days. The figures for ova kept 96 hours at 10° C. are not in agreement with this result; but the 46 per cent survival of the three-day ova is exceptionally high—perhaps because of the small number of cases.

(2) With storage at 0° C., normal development of one-day ova was very low after only 24 hours; but some young (6 per cent) were obtained after 96 hours storage. None of 59 three-day ova stored for 96 hours at 0° C., and transplanted among four does, developed into normal young. These results confirm that 10° C. is the optimal temperature for storage—as previously found[3] in a study on cleavage *in vitro*.

(3) When ova recovered at one day were cultured at 38° C. and then transplanted to the oviducts of does injected one day before operation, 20 per cent of those cultured 24 hours developed normally, and 27 per cent of those cultured 48 hours; but none of 109 ova cultured for 72 hours (six does) yielded normal young.

(4) The sex ratio of the young was not altered after storage *in vitro*; there is, therefore, no obvious differential mortality of the sexes at different storage temperatures. Of 429 young, only one, dead *in utero*, was abnormal, having a hernia and deformation of the fore limbs. It is probable that defective ova or embryos degenerated early. Because all non-pregnant animals were not sacrificed for examination, the recorded degeneration may be lower than its actual occurrence; several does were diagnosed as pregnant at two weeks but found to be not pregnant later, presumably owing to early degeneration of embryos.

Most of the ova that did not develop normally left no trace of having become implanted. Degeneration after implantation was more common with cultured or stored ova than after fresh transplantation. For does pregnant from freshly transplanted ova the mean litter size was 6·2, plus 0·58 degenerate. The corresponding figures for ova stored at 10° C. were 5·1 and 1·55, and for cultured ova 4·9 and 1·93.

(5) In the experiments previously mentioned, two-cell ova were transplanted to the oviduct; in other experiments (not shown in the table) they were freshly transplanted to the uterus. 92 one-day ova were divided among six does injected 72 hours before operation; none developed normally. 109 one-day ova were placed in the uteri of does 24 hours after injection; of the eight recipients one only became pregnant, the thirteen transplanted ova in this animal being represented at killing by a single normal fœtus, with no trace of other implantations. It seems that two-cell ova can survive *in vitro* at 0° C., 10° C. or 38° C., but fail to do so *in utero*.

(6) The following cases demonstrate the normal potentiality for development of large numbers of ova obtained by gonadotrophin injection; 53 two-cell ova from one doe, transplanted to four others, yielded 46 normal young. In another instance, 26 young were obtained from 35 two-cell ova divided among three recipients.

In conclusion, I wish to acknowledge my gratitude to Dr. Hudson Hoagland and Dr. Gregory Pincus for giving me the opportunity of working in their laboratory and especially to Dr. Pincus for advice. My thanks are also due to the Foundation for Applied Research, San Antonio, Texas, for a grant, and to Mr. Raymond A. Gunnarson for assistance.

Hearing in Cetacea

DR. FRASER's remarks in *Nature* of November 29, 1947, p. 759, on sounds emitted by dolphins reached me by sea transport shortly after I had made the following observations which appear pertinent to his subject.

While examining male adults of the sperm whale (*Physeter catodon*) on board this factory, I have established that the external auditory meatus is a short blind sac which penetrates from the auditory aperture a distance no deeper than the blubber thickness, and which has altogether lost organic connexion with the middle ear. The sac has somewhat thickened unpigmented walls wherein muscular tissue may be developed: internally, these walls are thrown into transverse folds. On the other hand, the blue whale and the fin (*Balænoptera musculus* and *B. physalus*) retain the normal mammalian pattern, and in these whales one can trace, from external aperture to tympano-petrosal bone, a continuous meatus the thin smooth epidermal lining of which is pigmented for the greater part of its length. Their Eustachian tube also presents no unusual features, but I have not so far been able to examine it in the sperm.

Obliteration of the meatal lumen in sperm whales must occur somewhere in the middle region of the canal, since dissection with steam-saw and axe reveals that the proximal portion, running in the temporal bone, is still intact. Also, in two physically immature adults examined, the external meatus, after termination of its cavity, was prolonged into a short solid stalk representing the canal after obliteration of its lumen. This suggests that the fœtal condition may exhibit a continuous meatus, but unfortunately sperm fœtuses are not available in the Antarctic.

There is evidence that the sperm whale dives to great depths, and it is apparent that permanent closure of the external auditory meatus has adaptive advantage in this cetacean, which must be capable of tolerating considerable changes in hydrostatic pressure.

The adult sperm whale can thus only hear by penetration of vibrations through the solid tissues of the head. In a mammal this does not appear an efficient path; but in the light of Dr. Fraser's remarks on the sensitivity of dolphins to supersonic emissions, it seems clear that such vibrations of high frequency and short wave-length would suffer considerably less absorption, during direct transmission through the sperm head, than sounds within the auditory range.

The experience of whaling gunners in catchers fitted with 'Asdic' gear shows that the larger rorquals, as well as dolphins, are, in fact, sensitive to supersonic vibrations. The 'ping' not only locates but also frightens the whale, which makes off at speed. This becomes an advantage should the catcher be fast enough to overtake its quarry, because when blue and fin whales are running they blow more often and are therefore more easily followed; moreover, they are sooner exhausted. The deliberate working of the 'Asdic' at 'short-interval transmission' to keep whales on the run has, in fact, been employed successfully in chasing.

I am indebted to both Messrs. Chr. Salvesen and Co. and to the Discovery Investigations for facilities enjoyed in the south.

A Plant Disease Caused by a Spore-forming Bacterium under Natural Conditions

THAT spore-forming bacteria, that is, species of the genus *Bacillus*, are responsible for some plant diseases has been recorded from time to time, but has rarely been confirmed; it is not yet generally accepted, as the great majority of bacterial plant diseases are known to be due to bacteria which do not form spores.

A few years ago, one of us (W. J. D.) recorded[1] the complete disintegration, under laboratory conditions, of the parenchyma of whole, or slices, of potato tubers, carrots, onions, cucumbers and iris stems by *Bacillus polymyxa* (Prazmowski) Migula, a soil-inhabiting organism. Madhok and Fazal-ud-Din[2] investigated a disease of tomato fruits which was also shown to be due to a species of *Bacillus* which they named *B. fructodestruens*, and the subject was further reviewed a few years later[3].

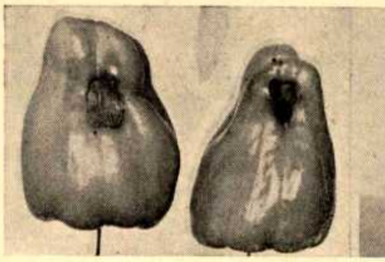

Fig. 1

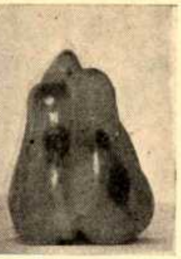

Fig. 2

Fig. 1. ORIGINAL FRUITS BROUGHT FROM THE SOUTH OF PALESTINE.
Fig. 2. INFECTION EXPERIMENT ON GREEN PEPPER FRUITS WITH THE ORGANISM ISOLATED FROM MATERIAL FROM THE SOUTH OF PALESTINE

Quite recently, one of us (Z. V.) has investigated a widespread fruit-spot of green pepper (*Capsicum annuum*) in Palestine, which was shown to be caused by a spore-forming bacterium identified at Cambridge as *B. polymyxa*. On the maturing fruits spots developed, one to five in number, light brown to grey, soft or firm, varying in size from 8 mm. to 12 mm. (Fig. 1). Microscopic examination of the softened tissues underlying the spots revealed the presence of numerous rod-shaped bacteria which were isolated in pure culture and produced subterminal spores. 48-Hour broth cultures were pasteurized at 85–90° C. for 10 min. and were used to establish cultures on potato dextrose agar from which suspensions in water were used for a series of infection experiments. Drops of the suspension were deposited on the surface of *Capsicum* fruits, which were then wounded by needle pricks. The inoculated fruits, placed under bell-jars over water, at room temperature (28–30° C.), developed lesions similar to those observed in the field (Fig. 2).

The organism was re-isolated from these spots, and the infection experiments were repeated with the re-isolated organism with like results. Controls pricked through drops of sterile distilled water did not develop any sort of infection. Various vegetables inoculated with the organism, under laboratory conditions, developed a typical soft rot of the parenchyma; but no infection of *Capsicum* was obtained either by spraying on a suspension of the bacteria or by inoculating wounds on *leaves*. This last observation is in agreement with that made at Cambridge with another strain of *B. polymyxa*, used to inoculate *stems* of iris and tomato plants which did not become infected, although kept under moist conditions and at a relatively high temperature.

It appears, therefore, that under *natural* conditions, involving high humidity and a relatively high (28–30° C.) temperature, the spore-former, *Bacillus polymyxa*, is a wound parasite, able to disintegrate the parenchyma of *Capsicum* fruits by means of its pectic enzymes.

B_T, A NEW VITAMIN OF THE B-GROUP AND ITS RELATION TO THE FOLIC ACID GROUP, AND OTHER ANTI-ANÆMIA FACTORS

By Dr. G. FRAENKEL

WITH THE ASSISTANCE OF

M. BLEWETT and M. COLES

Department of Zoology and Applied Entomology, Imperial College of Science and Technology

THE mealworm, *Tenebrio molitor*, has recently been shown to be a very suitable test subject for folic acid and certain other, still unidentified B-factors. When grown on an artificial diet consisting of casein (20 parts), glucose (80 parts), water-insoluble fraction from yeast (2·5 parts), cholesterol (1 part), a salt mixture (2 parts), and aneurin, riboflavin, nicotinic acid, pyridoxin, pantothenic acid, choline chloride and inositol in ample amounts, at least two more factors are essential for growth and survival, folic acid and a factor contained in a norite filtrate from yeast or liver extract[1,2]. In view of the present interest in the folic acid group and its relation to anti-anæmia principles, our recent results on the mealworm may be of general interest. Throughout this report the term folic acid has been used to denote pteroylglutamic acid.

TABLE 1. THE EFFECT OF PTEROYLGLUTAMIC ACID, YEAST CHARCOAL FILTRATE, LIVER CHARCOAL FILTRATE AND PARENTERAL LIVER EXTRACTS ON GROWTH AND SURVIVAL OF *Tenebrio molitor*. NOS. ALIVE (OUT OF 20) AND AVERAGE WEIGHTS AFTER 10 WEEKS AT 25° C.

Addition to basic diet		No.	Average weight (mgm.)
Pteroylglutamic acid	Source of B_T		
Absent	absent	all dead	—
Present	absent	all dead	—
Present	1% yeast	17	55
Absent	liver charcoal filtrate	10	12
Present	liver charcoal filtrate	17	48
Absent	yeast charcoal filtrate	9	10
Present	yeast charcoal filtrate	20	42
Absent, in its place parenteral liver extract			
Lederle	0·6 % liver charcoal filtrate	14	13·1
'Examen'	0·6 % liver charcoal filtrate	10	9·5

The relations of folic acid and the above-mentioned norite filtrate factor are shown in Table 1: in the absence of both factors growth is very slow and the mortality high. Addition of a charcoal filtrate from liver or yeast extract has always the effect of increasing length of life, without noticeably improving rate of growth. Folic acid alone sometimes to some extent accelerates rate of growth; but death usually occurs even more rapidly than on diets without folic acid. Only in the presence of both factors do growth and survival become normal, as compared with the effect of 1 per cent yeast (Table 1). For the sake of convenience we have tentatively named the norite filtrate factor 'vitamin B_T' (to indicate its activity on *Tenebrio*). *Tenebrio*, therefore, is an admirable subject for testing the activity of any substance in regard to its possible relation to folic acid or B_T; thus we can investigate the relationships of a number of substances which have come to light in connexion with and since the discovery of folic acid.

Pteroylglutamic Acid and Pteroylheptaglutamic Acid

It is now known that pteroylglutamic acid occurs in natural food substances largely in the form of 'conjugates' with glutamic acid. Of these, pteroylheptaglutamic acid, which had formerly been called vitamin B_c conjugate, was isolated from yeast. Recent reports emphasized that pernicious anæmia patients in contrast to normal subjects fail to utilize the conjugate as folic acid[3]. *Tenebrio*, similarly to the chick[4] and certain micro-organisms, utilizes pteroylheptaglutamic acid very well. Shortage of material restricted us to two series of tests which agreed in general trend, but not in detail (Table 2). In the first the minimum optimal dose was 0·5 μgm./gm. of the dry food with folic acid and 2·5 μgm./gm. with the conjugate, while in the second 0·12 μgm./gm. folic acid showed already an optimal effect, which only appeared with 10–20 times larger doses of the conjugate. However, in the latter case 0·12 and 0·25 μgm./gm. of the conjugate had already a marked effect.

TABLE 2. THE EFFECT OF PTEROYLGLUTAMIC ACID AND PTEROYLHEPTAGLUTAMIC ACID IN THE PRESENCE OF LIVER CHARCOAL FILTRATE ON GROWTH AND SURVIVAL OF *Tenebrio molitor*. NOS. ALIVE (OUT OF 20) AND AVERAGE WEIGHT OF LARVÆ AFTER 10 WEEKS

Experiment 367	Pteroylglutamic acid		Pteroylheptaglutamic acid	
Dosage (μgm/gm.)	No.	Av. weight mgm.	No.	Av. weight mgm.
0	3	10·6	3	10·6
0·1	12	23·3	9	17
0·5	16	51·2	16	39·8
2·5	18	54·8	15	50
10·0			18	52
Experiment 372				
0	17	14·5	17	14·5
0·125	18	53·5	18	23·3
0·25	20	53·5	19	28·1
0·5	20	47·2	20	38·7
1·0	18	59·7	19	42·2
2·0	18	51	18	50
4·0			20	53·5

These results, though rather incomplete, suggest that on a molecular basis the efficiency of pteroylglutamic acid and pteroylheptaglutamic acid cannot be very different.

There remained the possibility that pteroylheptaglutamic acid, which is the natural form in yeast, might have B_T activity as well as folic acid activity. This proved not to be the case; even very large quantities failed to give a survival effect in a diet which contained no source of B_T.

Pteroylglutamic Acid, B_T and Anti-anæmia Liver Extracts

After the activity of folic acid in the remission of pernicious anæmia had been discovered, it came as a surprise when statements appeared to the effect that purified parenteral anti-pernicious anæmia liver extracts did not contain significant amounts of folic acid[5] or of the conjugate[6]. These results have been fully confirmed in tests with *Tenebrio*. Two well-known commercial parenteral liver extracts were tested, one from Lederle Laboratories, Inc. (15 U.S.P. per ml.), and the other 'Examen' (Glaxo Laboratories). Neither of these preparations showed the slightest folic acid activity, as affecting the growth-rate, when tested in the presence of an effective supply of B_T in the form of a liver charcoal filtrate (Table 1).

Next the question arose as to the possible B_T effects of these parenteral liver extracts. Consequently a series of tests was set up in which folic acid was supplied as pteroylglutamic acid, and the effects of parenteral liver extracts compared in a series of concentration with that of a standard liver charcoal filtrate. No effect was recorded with 'Examen' in any of the concentrations used, while the Lederle extract gave a positive effect in

TABLE 3. COMPARISON OF THE EFFECTS OF YEAST, A LIVER CHARCOAL FILTRATE AND TWO PARENTERAL LIVER EXTRACTS AS SOURCES OF B_T. ALL DIETS CONTAIN 4 μGM./GM. PTEROYLGLUTAMIC ACID. NOS. ALIVE (OUT OF 20) AND AVERAGE WEIGHTS AFTER 10 WEEKS

Addition to diet	No.	Average weight (mgm.)
None	all dead	—
1% yeast	20	45·5
Liver charcoal filtrate, 0·6%	19	45
Parenteral liver extract		
Lederle, 0·075%	1	8
0·22%	3	13·3
0·66%	7	34·5
2·0%	15	39
'Examen' 0·075%	all dead	—
0·15%	all dead	—
0·3%	1	21
0·6%	1	13

a very large dose only (Table 3). It is somewhat difficult to compare the activity of liver preparations from different sources, even if the corresponding amounts of fresh liver from which they are derived are stated on the labels, as the total losses during preparation are unknown. The dry weights of the three preparations in question, and their fresh liver equivalents, were as follow:

	mgm./ml.	Liver equivalent
Liver charcoal filtrate	293	1 ml. ≡ 6 gm.
'Examen'	10	1 ml. ≡ 50 gm.
Lederle	140	1 ml. ≡ 100 gm.

The amounts in which these extracts were used in the diets are stated in Tables 1 and 3 as the percentages of the three solutions mentioned above added to the dry diet. For example, 0·6 per cent of an extract means that 0·006 ml. of it has been added to 1 gm. of the dry diet. It can then be immediately seen that the B_T activity of the liver charcoal filtrate is vastly greater than that of the 'Examen' or Lederle extract which derived from eight to sixteen times respectively larger amounts of liver. Similarly, 0·15 gm. of folic acid per gm. of the dry diet produced a good growth effect in *Tenebrio*. On the assumption that 1,000 lb. of fresh liver contains 1·5 gm. of folic acid[7], it follows that 1 gm. of fresh liver might contain 3·3 μgm. of folic acid, and an optimal effect should be induced with 0·05 gm. of fresh liver/gm. of the diet, that is, 5 per cent. On this reckoning, 'Examen' and the Lederle extract should have been equivalent to 5 per cent fresh liver in amounts of 0·1 and 0·05 per cent of the diet, while in fact they showed no effect in amounts of 0·6 per cent. Even allowing for the loss of appreciable amounts of active substances in such preparations, it remains obvious that the kind of activity for the purpose of which the anti-anæmia concentrates have been developed must by necessity be entirely different from that of folic acid or B_T.

It is interesting to record that similar results, stating the virtual absence of folic acid in six liver preparations of established clinical potency, have just been reported in tests which involved the use of another insect, the larva of a mosquito (*Aedes ægypti*). Here no relation could be found between folic acid activity, measured by the level of pupation response, and anti-anæmia activity[8].

Nature of B_T

The need for B_T by *Tenebrio* was originally discovered when, several years ago, attempts to grow *Tenebrio* on artificial diets had failed and a search was made into the nature of missing factors in diets for *Tenebrio* and other insects[1,2]. At that time the chief criterion for 'folic acid', as it was understood then, was adsorption on charcoal at an acid *p*H. It then became clear that *Tenebrio*, in addition to folic acid, required a liver or yeast fraction from which folic acid had been effectively removed by charcoal. It is, however, by no means certain that B_T remains quantitatively in the charcoal filtrate. In the course of our work, some loss of activity of filtrates, after treatment with charcoal, has sometimes been observed, up to about one third, though in most cases these losses were considerably smaller. This is important to keep in mind when comparing the properties of B_T with those of other unidentified B factors which have been reported from other laboratories. The existence of such factors adsorbable by charcoal but elutable with difficulty have, for example, been reported by Jaffé and Elvehjem[9] for the rat. A closer relation seems so far to exist in a guinea pig factor (*GPF* 3), described by Woolley and Sprince[10]. *GPF* 3 was not noticeably adsorbed on charcoal at *p*H 3·4, was not precipitated by lead acetate and was relatively stable to alkali. These properties seem to apply fully to B_T. A liver charcoal filtrate, which was treated with lead acetate, failed to show any loss in B_T activity.

Work undertaken at Cornell University with chicks[11] had revealed the presence in brewers' yeast of two essential nutritional factors which were termed *S* and *R*. These factors were afterwards shown to be separable by a simple charcoal treatment at *p*H 3·0 when *R* was adsorbed and *S* remained in the filtrate[12]. *R* was later found to be a folic acid conjugate[13]. So far the resemblance between B_T and *S* is very close. Recently, however, the Cornell workers[14] report the probable identity of factor *S* with strepogenin, a compound of polypeptide nature required by various micro-organisms. From our knowledge of the nature of B_T the possibility of its identity with strepogenin seems very remote, especially as our *Tenebrio* diet contains 20 per cent of casein, which is a very good source of strepogenin. In anticipation of facts to be discussed below, it is, however, relevant to record that chicks, on a factor *S*-deficient diet, fail to grow, become anæmic, show a generally weakened condition and usually die before they are eight weeks old.

Reports of additional unknown factors from yeast or liver, which are of importance for *Streptococcus fæcalis*[15], a monkey[16] and the chick[17,18] are not specific enough to allow comparison with B_T. B_T shows some features of the active principle in crude yeast or liver preparations, found by Wills to be effective in certain cases of nutritional anæmia which do not respond to parenteral liver extracts. The active principle of Wills's factor is not adsorbed on charcoal, and what has been so far published about its properties[19] shows a close resemblance to B_T.

It has been claimed in work with chicks, by Cornell workers, that for optimal effects of folic acid or 'conjugates' the addition of 4-pyridoxic acid lactone was required[20]. These reports made it possible that 4-pyridoxic acid might have B_T activity. 4-Pyridoxic acid in a wide range of concentrations was therefore added to purified diets which contained folic acid, but failed to reveal any B_T activity. The results of the Cornell group were not confirmed by two other groups of workers[4,21,22].

Attempts to isolate B_T from yeast and other natural products have been proceeding for some time in this Department, with the co-operation of Dr. A. H. Cook, of the Organic Chemistry Department of this College. The most active preparation so far obtained showed more than a hundred-fold concentration of B_T, and good responses have been recorded with quantities of roughly 3 μgm./gm. of the dry diet. By analogy with the activities of many of the known B-vitamins, it is reckoned that such concentrates may possibly contain 10–50 per cent of B_T.

Conclusions

The common mealworm, *Tenebrio*, has been shown to react very sensitively to the absence of folic acid and another, still unidentified, B-factor (B_T). This makes it an admirable subject for studying the folic acid or B_T activity of any known or unknown compound. There is reason to suspect that B_T may have some relation to the Wills's factor, and its similarity to factor *S* of the Cornell workers again points to a possible anti-anæmia effect. This would make *Tenebrio* an important tool in the study of anæmia, where the absence of a convenient testing organism has always hampered progress. But even if relations between B_T and anti-anæmia activity proved unfounded, a study of unknown B factors which have come to light in work with *Tenebrio* and other insects might still prove in the end to have a significance far beyond this class of animals. It has been shown again and again that the B-vitamins have all-important functions in the metabolism of all forms of life, from bacteria to man, and there has scarcely been a case of a new B-factor which was not ultimately proved to be of general significance. It is therefore perhaps not too much to hope that a further study of the nature and action of new B-factors in insects might, in the end, lead to the discovery of new principles of importance both in biology and medicine.

I wish to record my thanks to the Medical Research Council for a grant which made this work possible. Further, I wish to thank Lederle Laboratories, Inc., for pteroylglutamic acid and parenteral liver extract; Parke Davis and Co. for pteroylheptaglutamic acid (B_c conjugate); Merck and Co., Inc., for 4-pyridoxic acid; and Glaxo Laboratories for liver extracts.

Summary

The mealworm, *Tenebrio molitor*, requires for normal growth and survival, in addition to at least eight of the known B-vitamins, also folic acid and a new factor which has been tentatively named B_T. Folic acid conjugate can be utilized in the place of folic acid, but has no B_T activity. Concentrated parenteral anti-anæmia liver preparations do not contain significant amounts of either folic acid or B_T. The possible relation of B_T to other missing B-factors, reported from other laboratories, and to Wills's anti-anæmia factor is discussed.

AGRO-CLIMATIC ANALOGUES

By G. MELVYN HOWE
Commonwealth Bureau of Pastures and Field Crops,
Aberystwyth

THE majority of the cultivated plants of the eastern and western hemispheres are represented by totally different genera, and until comparatively modern times very few such plants were common to both hemispheres. Many of the cereal and legume crops cultivated in the Old World before the time of Columbus were quite unknown in America, and the reverse was equally true. The subsequent introduction of rubber into the Far East from the Amazon region, via Kew, is the classic example of plant introduction; but of equal importance we may note that of sugar cane from the East into the West Indies, potatoes from South America into Europe, cinchona from South America into the East Indies, groundnuts from Brazil into Africa and India, and in more recent years, soybeans from Manchuria into America and parts of Europe.

The Second World War witnessed, and to a certain extent was the cause of, increased numbers of plant introductions. This was especially so in the case of America, where numerous new plants were introduced in an attempt to overcome war-time shortages of various plant products. But it is with the urgent necessity of speedy rehabilitation of the many war-devastated agricultural areas at the present time that plant introduction assumes its greatest importance.

To facilitate agricultural rehabilitation the American Institute of Crop Ecology is at present engaged in publishing an International Agro-Climatological Series[1] which comprises studies dealing with North American agro-climatic analogues for the various countries of the world. Seven studies have already been published; another fifteen are in course of preparation. The objective of each study is "to organise, define, and analyse the various distinct agro-climatic conditions prevailing in the different parts" of the country under review and to compare them with the various agro-climatic regions of North America so as to determine "climatic analogues". Climatic analogues are defined as "areas that are enough alike with respect to some of the major weather characteristics affecting crop production, particularly during the growing period, to offer a fair chance for the success of plant material transplanted from one area to its climatic counterpart".

Each study gives a general and comparative geography of the country concerned and a brief account of its climate. Certain of the studies contain additional sections, as, for example, the one for the Ukraine, which also contains an account of the natural agricultural belts of the country and the major plant species of each, and the Albanian study, which gives an account of the natural vegetation, crop geography and agricultural practices of that country.

The source of the material for the main section of each study is the climatological data from the various meteorological stations of North America. The elements of comparison—monthly and yearly temperatures, maximum and minimum temperatures, average monthly, seasonal and yearly precipitation, precipitation-effectivity indices and ratios (Thornthwaite's method), length of frostless periods, and latitudes—are studied for a particular meteorological station and a search is then made among the North American stations for a "similar climatic and latitudinal environment". The North American environment when found is then noted as being climatically analogous to it. Relief maps of the country are presented to show the location of the various meteorological stations, and the names of States and regions of their North American climatic counterparts are given in each case, if such counterparts exist. Agro-climatic charts give full meteorological data for each observing station within the country studied and the North American climatic parallel of each.

This agro-climatological series by M. Y. Nuttonson, the background for which was developed by experiences gathered in non-emergency plant introductions where careful varietal field trials of introduced plant material were possible, will be welcomed by all plant exploration and introduction organisations, ecologists, agro-climatologists and geographers. Until such time as meteorological recording instruments are developed to give readings more in keeping with the requirements of agro-climatologists and such factors as evapo-transpiration and potential evapo-transpiration[2] are taken into account in the formulation of more detailed world homoclimes and agro-climatic analogues, they will serve as an excellent basis to all plant introduction work. It is to be hoped, however, that an institute similar to the American Institute of Crop Ecology will be set up in Britain to determine world homoclimes and agro-climatic analogues for the British Commonwealth. The Commonwealth Bureau of Pastures and Field Crops would appear to be the obvious centre for this work. Studies dealing with British Commonwealth agro-climatic analogues for the various countries of the world might well be initiated at this information Bureau. It would also serve as a pool for receiving suggestions from agriculturists and meteorologists concerning new types of meteorological instruments that should be evolved (for example, one for measuring water movement from the earth to the atmosphere) to meet the needs of the modern agro-climatologist and agriculturist generally.

Agricultural expansion in the British Commonwealth will most surely require, among other things, the introduction of new plant material into undeveloped or partly developed areas. Many of these areas will greatly benefit from new pasture plants, new legumes, etc., which might be obtained as a result of plant explorations in countries having similar homoclimes. For example, there is a proposal to send an Australian expedition to homoclimal areas in South America to study the more promising wild and cultivated plants with the view of transferring some to Australia. South America's richness in useful plant species is considered a valuable source for plant introductions for northern semi-tropical portions of Australia. Similarly it is proposed to send an expedition to Indo-China and Siam with the object of seeking and securing types of the banana family for use on the breeding work in the West Indies.

A series of studies such as have been suggested, dealing with British Commonwealth agro-climatic analogues for the various countries of the world, would undoubtedly facilitate plant introduction, adaptation and exploration work, and serve as a useful complement to the studies at present being carried out in the United States.

SOUTH AFRICAN MUSEUMS ASSOCIATION

ANNUAL GENERAL MEETING

THE twelfth annual general meeting of the South African Museums Association was held in the Africana Museum (Public Library building), Johannesburg, during March 16–19. The Mayor of Johannesburg, Mr. G. B. Gordon, opened the meeting on a particularly happy note by remarking on the Johannesburg City Council's appreciation of the value of museums and art galleries in the preservation of objects of art, science and history, and stating that education departments in various parts of the Union had already recognized their importance in adult and juvenile education. In the course of his address, Mr. Gordon also referred to his Council's pledge to establish, in collaboration with the University of the Witwatersrand, a museum of science and industry, and to its promise to provide a site for the South African National War Museum (at present housed in two Bellman hangars in a portion of the Zoological Gardens). By 1952, furthermore, he hoped that a new building to house the Africana Museum would be erected. From this, therefore, it would seem that Johannesburg can look forward to cultural developments with optimism.

Following the Mayor, Mr. R. F. Kennedy, retiring president of the South African Museums Association, presented his report for 1947. This made it clear that South African museums suffer as much from inadequate financial support as do a large number of the museums in Britain. Mr. Kennedy stated that though applications for increases in grants for museums had been made both to the Union Government and to provincial councils, there had been little or no response. (In spite of a steady rise in costs, grants for museums in South Africa have not altered materially since 1938.) In the case of the State-aided institutions, the Minister of the Interior had promised the formation of a special committee to study their particular needs; but no action, apparently, had actually been undertaken in this direction. Since, however, the State-aided museums now come under the Ministry of Education, there is hope that their problems will receive the attention due to them.

In his presidential address, Mr. Kennedy saw in 1948 the beginning of "a considerable development in museum work in South Africa", but he reminded delegates that the advancement looked for would depend not so much upon Government, provincial and local taxation as upon the museums themselves. "If the museums," he said, "can show that they have a rational plan, the support of the public through their representatives will be forthcoming." In this Mr. Kennedy spoke candidly and with truth, for in most South African museums at the present time there is much room for improved and more up-to-date methods of exhibition, and for the better presentation and co-ordination of the subjects with which they deal. Educational services for the general public, also, are far behind those rendered by some European and most American museums.

An important outcome of the Johannesburg conference was the formation of a special committee (to be known as the South African Museums Association Research Committee), to deal with all matters relating to research carried out by museums and allied institutions in the Union. South African museums have long been noteworthy for the amount and quality of the research they carry out in various fields; but it is now felt that there is need for the proper co-ordination of this work. This Committee, therefore, will henceforward act as the co-ordinating body. Its principal functions will be: (1) to advise Government and other authorities in matters concerning museum research; (2) to consider applications made by museums for grants, and to forward such applications with recommendations to the appropriate authority; and (3) to prepare a survey of the research already being carried out by these institutions with the object of co-ordinating this branch of museum work. Function (2), moreover, means that in future all applications from museums for research grants will automatically pass through the Research Committee for first consideration. The co-option on the same Committee of representatives of the South African Council of Scientific and Industrial Research, and of the South African Council for Educational, Sociological and Humanistic Research (constituted in 1946 by the Minister of Education to promote research in the humanistic fields), is a probability.

Another special committee which was formed at this year's meeting will press forward matters relating to increased Government support for South African museums and art galleries. It was decided, also, that a deputation from the Museums Association should ask the Transvaal Director of Education to urge the appointment of guide-lecturers for the instruction of school classes visiting Transvaal museums. The Transvaal Provincial Museum at Pretoria will send an independent deputation upon the same subject, and by now the City Council of Johannesburg will have been asked to act likewise.

The proceedings of this year's South African Museums Association conference, therefore, have made it clear that museum officials, and others interested in the work of museums, recognize the need for improvement in the Union's museum services; and from the strenuousness of discussion and the resolution which marked the whole of the meeting, there is every indication that the improvement looked for will come through equally strenuous action. One of the first necessary steps, however, will lie in an increase of staff trained in modern museum methods and technique.

Prof. R. H. Compton was elected president of the South African Museums Association for the coming year, and Mr. E. C. Chubb was re-elected secretary. In recognition of his long and valued service to the Association, Mr. Chubb was also elected an honorary life member.

During the conference, the Abbé Breuil, assisted by Miss Boyle, addressed the members on the Makhetha rock-shelter paintings of Basutoland and the Brandenberg rock-paintings of the Tsisab Ravine in South-west Africa; his very fine coloured drawings of these paintings decorated the walls of the conference room.

Members of the Association and visitors attended a reception in the Town Hall on the opening day of the conference, and on subsequent days visits were arranged to the University of the Witwatersrand, the Art Gallery, the South African National War Museum and the Union Astronomical Observatory.

A feature of the Johannesburg meeting was a special exhibition depicting the work, aims and needs of South African museums and art galleries. Coloured posters executed by the staff of the Africana Museum, and sets of photographs sent by individual museums and art galleries formed an attractive and informative introduction to this subject. The exhibit is available for the use of other South African museums. Its publicity value is high, and it is to be hoped that it will find its way to all museum centres in the Union. It was a pity that this exhibition did not get the press notice it deserved while it was in Johannesburg.

J. R. Harding

THE IMPERIAL INSTITUTE

The annual report of the Imperial Institute, South Kensington, London, for 1947 shows that an unusually large number of economic inquiries and laboratory tests have been made at the Institute for Empire Governments, industrial research organisations and commercial firms in search of new sources of raw materials. In the Plant and Animal Products Department alone, 203 samples were examined and 824 inquiries handled. Three scientific papers were published by the Department recording research work on methods of pyrethrum analysis carried out in collaboration with other authorities. The consultative committees on vegetable fibres, on gums and resins, on hides, skins and tanning materials and on insecticide materials of vegetable origin all met again once during the year, and matters which received attention included manila hemp, the utilization of linseed straw, the possibility of increasing production of rosin, and the insecticidal properties of *Cymbopogon giganteus* and *Neorautenania ficifolia*, from Northern Rhodesia. *Barataballi* latex, from British Guiana, has yielded a coagulum of some promise as an ingredient of the base for chewing sweets. Trials with new insecticides as preventives against hide beetle have been completed, and a report is being prepared. The Consultative Committee on Silk has submitted to the Secretary of State for the Colonies a statement on the need for a programme of sericultural experiments in the Colonial Empire, and has also prepared for the High Commissioner for Southern Rhodesia a report on the nature and scope of such experiments that might be undertaken in Southern Rhodesia.

Investigations reported during the year dealt with wattle bark from Jamaica, cutch from Burma, *Melaleuca bracteata* oil from Kenya, a possible source of methyleugenol, citrus oils from Palestine, shark liver oils from Trinidad, tung oil from Nyasaland, soya beans from Nigeria and tobacco from Cyprus. Of the 824 inquiries, the report mentions particularly those relating to lemon juice and peel, papain, jute and jute substitutes, cellulose for wood and rayon pulp and short-length piassava from Sierra Leone.

The Intelligence Section of the Mineral Resources Department dealt with 1,048 inquiries, and among these vermiculite continued to figure, while other inquiries related to supplies of beryl, zinc deposits in Burma, Empire resources of sillimanite minerals, Indian and Australian pyrophyllite, barytes for oil-well drilling muds, and clays for bases in soap substitutes. Staff limitations have prevented resumption of the preparation of revised editions of the series of mineral monographs, but the mineral resources section of the quarterly *Bulletin* of the Institute has continued, and results of the investigations on samples of coal from Tanganyika were published as an appendix to an article in the *Bulletin* on the geology of the Namwele-Mkomolo Coalfield by R. B. McConnell. Among the investigations carried out during the year may be recorded those on bleaching earth from Cyprus, lignite from Sierra Leone, manganese ore from Dominica, and clays, coral, volcanic materials and sands from St. Vincent as possible building materials.

The Rubber Department gave its chief attention during the year to a continued study of the resilience of rubber, and improvement in resilience of *Hevea* rubber by thorough purification previously reported has been confirmed. The vulcanizing and mechanical properties of the highly purified rubber have been studied in some detail, as well as the effect of treating the latex with substances likely to affect molecular cohesions and linkages. Attempts have also been made to determine the association of phosphorus with the rubber particles in preserved latex.

The report also includes an account of the educational work of the Institute, both its publications and exhibitions, the Central Film Library, the Empire Lantern Slide and the Film Strip Library and the general library, to which more than 5,700 books, official reports and pamphlets were added in 1947, in addition to the 800 periodicals normally received.

THE FISHERIES SCHOOL AT CRONULLA, NEW SOUTH WALES

ONE of the most interesting and informative technical publications issued in connexion with any fishing industry is the *Australian Fisheries Newsletter* published by the Commonwealth Fisheries Office. This first-rate monthly never fails to provide a wealth of accurate and helpful information covering all aspects of Australian fishing activities together with a useful leavening of articles and news items dealing with the more general aspects of marine biology and its bearing on fisheries problems in all parts of the world. Of particular interest has been a series of articles* on the foundation and development of a fisheries training school on a site adjoining the Marine Biological Laboratory of the Australian Council of Scientific and Industrial Research in New South Wales.

The Australian fishing industry at the present time employs some ten thousand persons in actual fishing. No accurate figures are available concerning the number of persons engaged in ancillary occupations. Very rapid developments were made during the Second World War, and since the conclusion of hostilities there has been a heavy influx of new personnel. Many of those have come from families already in the industry; but there is also a steady recruitment of ex-Service men without previous experience of any branch of fishing activity. In order to ensure that those men shall have the best possible chance of making good in their new occupation a Commonwealth Fisheries School has been established at Cronulla, New South Wales, well equipped and adequately staffed for the work it sets out to do.

A technical supervisor is responsible for technical training. He is assisted by an assistant technical supervisor, and the masters and crews of the school's instructional vessels, which comprise a 75-ft. diesel trawler, a 66-ft. Danish seiner, a 25-ft. inshore motor fishing vessel and several smaller boats.

The more theoretical side of the instruction is given by officers of the Fisheries Division and the Division of Food Preservation and Transport of the Council of Scientific and Industrial Research, the staff of the Sydney Technical College, and members of the Commonwealth Fisheries Office.

The trainees reside on the premises, so a camp superintendent is in charge of the school buildings, assisted by a quartermaster, cooks and camp attendants. There are thirty bedrooms, each accommodating two persons, and a 'loughboy' for storing clothes and other personal gear. Adequate bathing facilities and a laundry are also available. The large messroom can accommodate seventy persons, and the catering staff, operating an all-electric kitchen, provide a good service of both hot and cold meals.

Approved applicants accepted for full-time training pay no fees for the course. Where necessary, an allowance is made for books, tools and other essentials, and, in addition, a living allowance of £3 5*s*. a week is paid to those without dependants. To a trainee with dependants an additional sum up to a maximum of £2 a week may be paid, according to the number of dependants and their degree of dependency.

The course at Cronulla was originally planned to extend over four months, after which the trainees were required to go into subsidized employment in the fishing industry in order to obtain further intimate experience of practical work. Difficulty has been experienced, however, in placing the trainees in subsidized jobs because fishing in Australia is mostly operated by one-man boat-owners, by crews who are joint owners of their own boat, and by owners with crews on a share basis. It has therefore been decided that the training course shall be extended from four months to thirty weeks and that the period of subsidized employment be abolished. It is thought that the longer course will provide sufficient practical experience in the fishery school's own vessels to enable its students to stand at once on their own feet in the fishing industry. To assist in achieving this objective some of the theoretical instruction given during the first course will be reduced and more time given to practical work both at sea and on shore. For the first twenty weeks all trainees will take the general fisheries syllabus, after which they will specialize in that branch of the industry which they intend to enter.

---

* *Fisheries Newsletter*, 5, No. 2, 3 (April 1946); 6, No. 1, 3 (Feb. 1947); 6, No. 2, 8 (April 1947); 6, No. 5, 3 (Oct. 1947). Published by the Commonwealth Fisheries Office, Dept. of Commerce and Agriculture, at the Publicity Press (1938) Pty., Ltd., 71–75 Regent Street, Sydney.

It is felt in some quarters that a school of fishing should be established in Great Britain, particularly for the training of fishery officers and others who will be going out to British Colonies under the Colonial Development Scheme. It is doubtful whether there would be enough trainees derived from this source to support a satisfactory school on a permanent basis. But the British fishing industry also would benefit if the recruits to its ranks could have a period of training in a well-planned and wisely conducted school of fisheries such as that at Cronulla. Fishing in Britain and other European countries has long ceased to be run on primitive 'rule-of-thumb' lines, and there seems at present to be a decided danger that British fishermen may be outstripped by Continental rivals who give more attention to the proper study of fishing in all its aspects. G. A. STEVEN

BOTTOM DEPOSITS OF LAKE WINDERMERE IN RELATION TO THE QUATERNARY HISTORY OF THE BRITISH ISLES

THE importance of the bottom deposits of Lake Windermere as a source of information concerning the post-glacial history of north-western England has already been indicated by the stratigraphy and diatom sequence established by Winifred Pennington (Mrs. T. G. Tutin) (*New Phytol.*, 42, 1; 1943). These deep-water deposits (brought within reach by the unique qualities of the Jenkin core-sampler) have been used again by the same worker to extend our knowledge into the late-glacial period (*Phil. Trans. Roy. Soc.*, B, 233, 137; 1947). Water-laid, laminated clays are found above and below a layer of grey detritus silt which contains remains indicating that it was laid down during a cool-temperate phase. This is tentatively correlated with the Allerød oscillation established in north-western Europe and Ireland.

Analysis of the post-glacial layers (utilizing both pollen and macroscopical plant remains) reveals a fairly close correlation with events in East Anglia, except in the later stages where a *Salix* maximum occurs in Zone IV and *Betula* assumes, in Zone V and early Zone VI, the dominance characteristic of profiles from the west of Britain. *Tilia* does not appear until Zone VII, and *Fagus* and *Carpinus* are completely absent. *Pinus*, which appears to be consistently over-represented in the deep-water deposits, falls off very rapidly at the transition between Zones VIc and VII, but always reappears at a characteristic position near the surface, where the brown and indurated clay gives way to soft, black, rather unconsolidated gyttja. This reappearance may be due to planting (a rise in the importance of grass pollen in deposits laid down 2,000–2,500 years ago having already suggested the beginning of clearance of the primeval forests).

Samples from beneath shallow water provided the clearest pictures of the late-glacial and early post-glacial changes, but deposition appears to have ceased (due to turbulence) when the mud has approached to within about three metres of the water-surface. The lesser clarity of the early stages of deep-water samples appears to be due to a very slow deposition here.

Possible correlations of dating with geological reports for north-western England, Ireland and Scandinavia are clearly shown in tabular form, and it is concluded that the lower laminated clay is contemporaneous with the Scottish re-advance, the Carlingford re-advance in Ireland and the Lower *Dryas* clay in Denmark, and its end is placed at about 10,000 B.C. The commencement of the deposition of the upper laminated clay is placed at 8,300 B.C., and its continuation for some four to five hundred years (estimated by counting the varves) is believed to be the result of a valley glaciation in the Lake District. This is correlated with the Antrim coast re-advance and valley glaciation in the Wicklow Mountains, the Upper *Dryas* clay of Denmark and the formation of the great Fenno-Scandian moraines. In the post-glacial period, a dating between 6,300 and 6,000 B.C. for the Boreal-Atlantic transition also agrees with Scandinavian results.

A brief correlation with the previous work is made and the greater detail revealed by pollen-analysis is demonstrated, while the same technique is also made to shed further light on the stratigraphical results previously obtained. H. G. BAKER

THE NORWEGIAN POLAR INSTITUTE

ON March 1, the Norwegian Polar Institute (Norsk Polarinstitutt) was established in Oslo in order to continue and expand the activity of Norges Svalbard- og Ishavs-undersøkelser. The latter office was founded in 1928, when it took over the work which since 1909 had been carried out by Government-supported expeditions to Svalbard. Norges Svalbard- og Ishavs-undersøkelser has been engaged in the preparation of topographic maps and hydrographic charts of the Svalbard region and in geological investigation on Svalbard. It has provided facilities for numerous scientific workers to visit Svalbard and Eastern Greenland, and has carried out a large amount of practical work such as the establishment of aids for navigation and maintenance of weather stations.

Besides continuing this work, the Polar Institute will broaden the scope of the scientific activity, partly by adding specialists of its own permanent staff, and partly by securing the collaboration of specialists who are connected with university institutions in Oslo and Bergen and other scientific organisations. The sphere of interest will be expanded to include the regions of the Antarctic over which Norway claims sovereignty. It is hoped that the Polar Institute will be able to undertake, sponsor or stimulate geological and palæontological research, glaciological and meteorological studies as well as work in the fields of zoology and botany. The publications of Norges Svalbard- og Ishavs-undersøkelser (*Skrifter* and *Meddelelser*) will be continued from the Polar Institute without any break in the numbering.

The Polar Institute will not absorb organisations which are primarily engaged in scientific work in the polar regions, such as the Aurora Observatory at Tromsö or the Government Institute of Whaling Research in Oslo; wherever desirable, it will collaborate with these organisations.

The Polar Institute comes under the Department of Industry of the Norwegian Government, but Dr. H. U. Sverdrup, who has been appointed director, has also been attached to the University in Oslo. He will be able to accept special students at the Institute and thus to attract the attention of young men to the problems of the polar regions. Dr. Sverdrup, until this year professor of oceanography in the University of California and director of the Scripps Institute, has himself had a distinguished career as arctic explorer, oceanographer and mathematician. He is perhaps best known for his observations of the tidal currents over the Siberian Shelf made during the Norwegian expedition of the *Maud*, and for his two recent books—the part dealing with physical oceanography in "The Oceans" and his "Oceanography for Meteorologists", of which an edition has been published in Britain. He has taken an active and leading part in modern oceanographical research.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, June 21

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 8.30 p.m.—Dr. Isaiah Bowman: "The Geographical Relation of the U.S.A. to World Policies".

Monday, June 21—Friday, July 2

Royal Society (at Burlington House, Piccadilly, London, W.1).—Conference on "Scientific Information Services".

Tuesday, June 22

Royal Anthropological Institute (joint meeting with the International African Institute, at 21 Bedford Square, London, W.C.1), at 5 p.m.—Dr. K. L. Little: "The Secret Society as an Arbiter of Culture" (Discussion Meeting).

Wednesday, June 23—Friday, June 25

Institution of the Rubber Industry (at Central Hall, Westminster, London, S.W.1).—Rubber Technology Conference.

Thursday, June 24

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir George Thomson, F.R.S.: "Nuclear Explosions" (Bakerian Lecture).

Mineralogical Society (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Thursday, June 24—Friday, June 25

Genetical Society of Great Britain (joint meeting with the British Empire Cancer Campaign, at the Royal Society of Medicine, 1 Wimpole Street, London, W.1).—Symposium on "The Genetics of Cancer".* (Afternoon Session on Thursday afternoon, at 2.30 p.m., at the Medical Society of London, 11 Chandos Street, London, W.1.)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Director of the Research Institute of Launderers, Drycleaners and Dyers of New Zealand—The Scientific Adviser, New Zealand Scientific Office, B.C.S.O., Africa House, Kingsway, London, W.C.2 (June 23).

Readership in Biochemistry at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 23).

Assistant in the Department of Physiology, a Lecturer in Clinical Chemistry, and a Lecturer in the Department of Physiology—The Secretary, The University, Aberdeen (June 25).

Lecturers (3) in the Chemistry Department, Lecturers (2) in the Physics Department, and a Lecturer in the Chemical Engineering Department—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (June 26).

Senior Lecturer in Mathematics—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (June 26).

Lecturers (2) in Geology—The Registrar, King's College, Newcastle-upon-Tyne (June 26).

Assistant Examiners in the Patent Office under the Board of Trade—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting No. 45A (June 30).

Grassland Agronomist, and a Plant Breeder with training in mycology—The Director, Welsh Plant Breeding Station, Agricultural Research Building, Penglais, Aberystwyth (June 30).

Lecturer in Botany in the United College, St. Andrews—The Secretary, The University, St. Andrews (June 30).

Tutorial Research Studentship in Mathematics (Pure or Applied)—The Principal, Royal Holloway College, Englefield Green, Surrey (June 30).

Assistant Lecturer or Lecturer in Geology—The Secretary, The University, Aberdeen (June 30).

Lecturer in Metallography in the University of Melbourne—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (June 30).

Patent Officers under the Ministry of Supply—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 2175 (June 30).

Research Fellowships in Mathematical Physics—The Secretary, The University, Edmund Street, Birmingham 1 (July 1).

Research Award in the Department of Physics—The Registrar, University College, Hull (July 2).

Research Officer in the Division of Industrial Chemistry for the investigation of relationships between the molecular structure and dielectric properties of electrical insulating materials—The Secretary, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 1701 (July 3).

County Horticultural Instructor (male) on the staff of the Somerset Farm Institute, Cannington, Bridgwater—The Chief Education Officer, County Hall, Taunton (July 3).

Head of the Department of Agriculture, a Head of the Department of Veterinary Science, and a Head of the Department of Forestry, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (July 3).

Professorships of Pharmacology, Entomology, Protozoology, and Pathology and Bacteriology, at the School of Tropical Medicine, Calcutta—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2, quoting No. 4/26A (July 5).

Lecturer in the Department of Botany, University of Cape Town—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Cape Town, July 15).

Professor of Civil Engineering Construction and Foundations, a Professor of Strength of Materials, a Professor of Hydraulics and Water Power, a Professor of Steel Bridges and Metallic Structures, a Professor of Line Telephony and Telegraphy, and a Professor of Electric Power Stations, at the Farouk I University, Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (July 15).

Challis Chair of History in the University of Sydney—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 31).

Professor of Mathematics and Head of the Department, and a Professor of Mathematical Physics, in the University of Cape Town—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 31).

Chair of Electrical Engineering in the University of Sydney—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Sydney, August 15).

Lecturer in Mathematics—The Registrar, The University, Reading.

Professor of Physics and Electrical Engineering, and a Lecturer in Applied Mechanics, at the Royal Naval College, Greenwich—The Director (P.A.), Education Department, Admiralty, London, S.W.1.

Research Statisticians and Assistant Statisticians—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Lecturer in Botany, and a Lecturer in Economics, at the Imperial College of Tropical Agriculture, Trinidad—The Secretary, Imperial College of Tropical Agriculture, Grand Buildings, Trafalgar Square, London, W.C.2.

Laboratory Assistant with experience of chemical and/or biochemical analysis—The Department of Veterinary Hygiene and Preventive Medicine, Royal (Dick) Veterinary College, Edinburgh.

Senior Lecturer and Lecturer in Physics in the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2.

Physicist, and a Chemist—The Director of Research, British Hat and Allied Feltmakers' Research Association, Department of Textile Industries, The University, Leeds 2.

Senior Technician in the Pharmacy and Biology Laboratories—The Secretary, Royal Technical College, Glasgow.

ETHICAL BASIS OF ATOMIC ENERGY CONTROL

THE debate in the House of Commons on May 14 on the international control of atomic energy added little to what had been said earlier in the House of Lords. Mr. Mayhew, Under-Secretary of State for Foreign Affairs, made it plain that the Government accepts the view that in the present circumstances no progress is possible on the Atomic Energy Commission; but that if a solution of the atomic energy problem could be reached at all, it will be through the machinery of the United Nations. The Government has agreed to the suspension of the discussions for the time being because no effective system of international control is possible without a voluntary merging of some part of national sovereignty. Unlike ten out of the twelve nations represented on the Commission, Soviet Russia, he said, is unwilling to take this step, just as she refuses the complete openness also essential for the success of a scheme of international control.

The most interesting feature of the debate was the reference in Mr. Blackburn's speech, in raising the question, to Sir Edward Appleton's remark on May 13 that there is unlikely to be any final solution to this problem merely along technical lines. Mr. Blackburn added that he does not believe this problem will be solved without a religious revival, which would concentrate the minds and hearts of men upon loftier ideals than the materialistic ends with which we are so often confronted. This sentiment was echoed in other speeches in the debate, and was reflected both in the meeting held in London in the Albert Hall on April 26 to demonstrate the support of the Christian community for the idea of Western union and in other comments on that proposal, and in Mr. Churchill's notable speech at The Hague to the United Europe Congress on May 7.

Mr. Churchill urged that the movement for European unity must be a positive force deriving its strength from our common sense of spiritual values. It is a dynamic expression of democratic faith based upon moral conceptions and inspired by a sense of mission. In the centre of the movement stands a charter of human rights guarded by freedom and sustained by law. Moreover, the movement aims, he said, at the eventual participation of all peoples throughout the Continent of Europe, whose society and way of life are not in disaccord with a charter of human rights and the sincere expression of free democracy.

Mr. Churchill recognized that the world organisation cannot function without the active help of the third great and equal partner, nor can the shadow of war be lifted yet from the hearts and minds of men and nations. Meanwhile, we can create and combine the great regional unities and endeavour to prepare by patient and faithful service for the day when an effective world government will rest on the chief groupings of mankind. This main endeavour can lay the moral and spiritual foundations on which the statesmen of the Western democracies will be able to build the organisation which will achieve freedom from fear—the freedom that matters most to-day.

Mr. Churchill's speech and the Congress itself should do something to foster a return to the confidence in Western democracy and in the personal and spiritual values upon which it rests.

Whatever form Western union may take—and the growth of the movement in the last six months has been remarkable—it represents a real determination among the peoples of Western Europe to preserve and strengthen their free way of life against the threat of Communism; and at the same time, it means not only a belief in the true values of Western civilization but also a knowledge of what Western democracy ought to represent. That implies a task of education as well as readiness to work for the ideal and determination to uphold it against challenge. Only as that task of education proceeds can there be created the volume of informed opinion which will afford not merely the moral support but also the close and understanding criticism which the statesmen of Western Europe will need as they deal with the many thorny problems confronting the working out of concrete proposals for closer union, with the sacrifices in national sovereignty that are involved.

It was a main purpose of the Albert Hall meeting to mobilize Christian effort and Christian faith in Western Europe behind the political, social and economic drive to turn our future into ways of peace and harmony. Material means, as Sir Stafford Cripps said, must be directed by spiritual vision, and the methods used inspired by those great traditions that have been built up in Western Europe through the centuries; and in a message to the meeting, Mr. Churchill asserted that the movement for Western union would come to naught unless the structure of the new Europe was built firmly upon moral and spiritual foundations. The question of atomic energy is only one facet of that problem of building an order in which there is freedom from fear. The report of the commission appointed by the Archbishops of Canterbury and York in 1946 to consider the British Council of Churches report on "The Era of Atomic Power" is, as might be expected, largely concerned with the moral issues which have been so prominent in the movement for Western union; and it indicates very clearly how much there is to be done before we can achieve a common mind on questions of policy which touch spiritual issues, or even make clear precisely what we understand by the moral and spiritual foundations of Western democracy.

The scope of the report is better indicated by its sub-title, "A Study of the Moral and Theological Aspects of Peace and War", than by its title, "The Church and the Atom"*. Indeed, it scarcely touches on the ethical aspects which have so much concerned scientific workers, and which found a place in the B.B.C. talks on atomic energy in March last year. The Commission is, however, somewhat critical of the earlier report, "The Era of Atomic Power", one chapter seeking to correct the work of that Commission by setting atomic warfare in the context of warfare in general and of the doctrine of 'the just war', and to disentangle the moral question from that over-insistence on the divine right of Western democracy which in "The Era of Atomic Power" tended to darken counsel.

What is said in this chapter should be pondered carefully. After setting forth the three accepted grounds or causes of a 'just war', it is observed that if in future the nations agree to establish an international tribunal, the definition of 'just cause' will have to be modified accordingly; the Commission then proceeds to elaborate the Christian tradition that a belligerent should always have as his ultimate end the establishment of peace founded on justice. It insists that there is also a proximate end which is determined by the particular justifying cause, and in this connexion it insists that a belligerent ought not to use more force on the whole than is needed to bring the enemy to terms, and that in the choice of weapons and methods of warfare he should always keep the limited end steadily in view, preferring methods of which the ill-effects are least persistent. A belligerent should do nothing unnecessarily to prejudice the incorporation of his enemy into the community of nations when once the war is ended. In short, the object of warfare is not to kill the enemy, but to disarm and so overpower him.

This is the doctrine by which the validity of strategic bombing and atomic weapons are assessed. The Commission is agreed that the 'obliteration' bombing of whole cities with high-capacity and incendiary bombs must be condemned. It is inconsistent with the limited end of a just war and violates the principles of discrimination just noted: it constitutes an act of wholesale destruction that cannot be justified.

Moral principle thus imposes, in the view of the Commission, considerable restriction on the use of strategic bombing as a means of warfare. Nevertheless, while maintaining that weapons of destruction should only be used in accordance with the moral rules that apply to them, and that these rules cannot be disregarded if the intention is not primarily to destroy but to administer "psychological shock", the Commission does not condemn outright all use of atomic power in war. Refusing to abandon the medieval conception of 'the just war', the majority of the Commission rejects Mr. Henry Stimson's justification of the use of atomic bombs in 1945, but believes that in certain circumstances defensive 'necessity' might justify their use against an unscrupulous aggressor. On the assumption that possession of atomic weapons to-day is genuinely required for national preservation, a Government is entitled to manufacture them and hold them in readiness. Moreover, the Commission considers that if any nation, or any group of nations, which is resolved to resist unscrupulous aggression, lets it be known that it holds itself entitled to defend itself in this way, such warning might go far to prevent the abuse of atomic weapons.

On moral grounds, therefore, the Commission appears to support the opinion that has often been expressed that, in view of Russian intransigence on the vital question of inspection, those nations prepared to make the sacrifice of national sovereignty should go ahead with such a scheme as has been approved by the majority on the Atomic Energy Commission. Even more pointedly, the Commission observes in its conclusions that the law of Nature requires all peoples to co-operate in promoting a world-order based on justice, and that at present the chief obstacle to such co-operation is found in the quasi-religious convictions and claims made by the U.S.S.R. The duty of fashioning a world-order remains none the less, and the Commission believes that Christians and all who recognize the claims of reason and justice should combine in attempting this work.

---

* The Church and the Atom: a Study of the Moral and Theological Aspects of Peace and War. Pp. 130. (London: Church Assembly, 1948.) 4s.

Other sections of the report, for all its caution and qualifications, are no less clearly a challenge to thought on the problem of power and its control, and the cultural, political and religious aspects of that problem. The Commission accepts Dr. Toynbee's view that the breakdown of civilizations has been due to internal and not external causes. The task that confronts us to-day is in part, as the movement for Western union recognizes, that of achieving political co-operation and spiritual unity; but it is bound up with the fact that the vast resources of physical and mechanical power which science and technology have put into man's hands can only be developed by the governments of wealthy and highly organised nation-States.

The Commission addresses itself to these questions in its final chapter, "Christian Duty in a World of Power", in which the man of science will find much to weigh and develop. In an earlier chapter, the Commission does not reject as explicitly as some have done the doctrine of neutrality in warfare, though by inference it appears to do so; but it does call for an effort to achieve a fuller understanding of the true order of human purposes which knowledge ought to serve. It upholds the emancipation of science and rejects the suggestion of an arbitrary restriction of scientific research, setting science rather in its true context as one phase of culture. Like the earlier report, "The Era of Atomic Power", it pleads for the achievement of 'wholeness of life', in which all science and all activity are duly subordinated to the knowledge and love of God to cure the fragmentation and distortion of truth caused by excessive specialization.

It is interesting to note the suggestion that science and religion should find their common meeting place not only in the field of reason but also of the imagination. We need to recognize, the Commission urges, far more commonly than we do, the large part played by intuition and imagination in scientific and technological research. Moreover, human society cannot do without the kind of insight and imagination which humane interests and studies alone can give; it is indeed for lack of these that civilization is perishing. The real safeguards against the abuse of knowledge are, in fact, spiritual and educational.

A better balanced education and the breaking down of barriers between the various fields of knowledge are necessary means to the achievement of unity, and the Commission welcomes the foundation of the United Nations Educational, Scientific and Cultural Organisation as evidence that most civilized nations recognize the importance of the cultural factor. It insists, however, that the exclusion of religion from its purview vitiates the work of the Organisation, no less than its failure to recognize the need for a principle of unity in the cultural realm. Once again, in relation to proposals for a world authority or for an effective organisation for the control of atomic energy, the Commission records its conviction that fundamentally the problem of peace is spiritual rather than political.

Here the Commission goes down to fundamentals, and in this respect the report is of more value than the comments now included with the symposium of talks on atomic energy arranged last year by the B.B.C. (see p. 995 of this issue of *Nature*). Mr. N. Loewenstein, it is true, points out that we are still in search of some international code of morality as a substitute for a previous international religious faith, but no other commentator appears to see further than the necessity for some surrender of national sovereignty.

In the talk by Mr. H. A. Wallace with which the book concludes, it is pointed out that there may be no future unless the freedom of man and the peace of the world are preserved. Freedom is essential to science, nor can science come to full fruition except in a world at peace. Science is one of the cultural activities of man, one of the ways in which his creative powers and his questing spirit find expression. For that reason, if for no other, scientific workers cannot stand apart, either from the study of the moral and spiritual aspects of peace and war of which the report "The Church and the Atom" is one expression, or from those movements which, like that for Western union, are bringing about a rebirth of the European spirit and a fresh affirmation of the faith on which European civilization, to which science itself owes so much, has been built. However imperfect may have been the formal resolutions adopted at the Hague Conference, all present realized that the foundation of European unity is not material but spiritual, a common sense of ultimate values transcending all national ideological and religious differences. Science, which in itself makes such an important contribution to cultural unity, cannot but applaud the rebirth of that spirit of unity.

MINERAL RESOURCES OF THE UNITED STATES

Mineral Resources of the United States

By the Staffs of the Bureau of Mines and Geological Survey. Pp. x+212. (Washington, D.C.: Public Affairs Press, 1948.) 5 dollars.

THE pre-eminent industrial position of the United States is based upon her vast mineral resources. In many fields, her production of mineral raw materials exceeds that of any other country, a fact which had an important effect upon the course of the Second World War. The war-time acceleration of production revealed, however, that some branches of the mining industry were not equal to the strain, emphasizing, in addition, that for a few essential mineral commodities, the United States are necessarily dependent on foreign sources. To meet anxious questionings at the end of the War, a quantitative appraisal of mineral reserves was jointly undertaken by the United States Bureau of Mines and the Geological Survey, these organisations having carried out, with Congressional authority, very extensive investigations for new and marginal sources of supply. The results of the survey were given in evidence before a sub-committee of the Senate Committee on Public Lands, a small edition being published late last year. This does not appear to have been available in Great Britain. The present edition, with the text unchanged, is welcome because it will bring the facts to a wider public; and because the mineral resources of the United States have more than a purely domestic interest.

Owing to the complexity of geological conditions, no assessment of mineral reserves 'in the ground' can be more than an approximation; the available data vary from deposit to deposit and in general become less reliable as the appraiser passes from the single mine to the mining district, and thence to the country as a whole. Estimates of measured (proved) and indicated (probable) reserves must come in the main from industry itself. In highly competitive branches of the mining industry there is a natural reluctance on the part of the companies to divulge their reserves. Assessment of inferred (possible and speculative) ore can best be carried out by government agencies, who are in a better position to see the picture as a whole. The account recognizes frankly the inadequacies of the data but maintains, I think rightly, that within their limitations the figures give a useful picture of the present situation and the possibilities of the immediate future. It is not claimed that they portray the ultimate mineral wealth of the United States.

The overall picture is, on the whole, a favourable one. Thirty-eight mineral products are discussed, with tables, maps and curves of production. Virtual self-sufficiency, even in times of emergency, is assured for a long time in bituminous coal, lignite, anthracite, natural gas, magnesium, molybdenum, metallurgical-grade fluorspar, helium, magnesite, nitrates, phosphates, potash, salt and sulphur. Improvements in technology and economic changes sufficient to bring submarginal reserves into use would add petroleum, aluminium, copper and iron ores to the list. Dependence on foreign sources is confined to chromite, ferro-manganese, nickel, the platinum group metals, tin, diamonds, quartz crystals and asbestos. In the remaining minerals there are partial deficiencies.

Not merely the actual or impending shortages, but also the needs of production lead inevitably to the recognition of the importance of scientifically planned exploration, in which the geologist, geophysicist, geochemist and mining engineer each has his part to play. Behind the technologists there is the dilemma: Should the search be left to private industry, or should it be integrated in a national plan? The authors have no doubt that the latter alternative would give the best results, and it should be remembered that their view is based upon war-time experience of integrated research.

This unique assessment of a nation's mineral resources, valuable to legislators, producers and consumers under a 'free' economy, would appear to have double value in a 'planned' economy. Could such an appraisal be made for British resources? Many of the basic data are in existence. Coal reserves, first estimated by the Royal Commission on Coal Supplies, 1905, are given region by region in the series of regional survey reports published by the Ministry of Fuel and Power during 1945–46. Iron ore reserves have been studied in detail by the Geological Survey and publication is in progress. For the non-ferrous and allied minerals, Geological Survey investigations in collaboration with the war-time Non-Ferrous Development Committee (Ministry of Supply) cover most of the facts. Since the War a Minerals Development Committee (Ministry of Fuel and Power) has been set up. Possibly, however, a more useful picture would be obtained were an attempt made to sum up the resources of the Commonwealth and Empire rather than the reserves of the British Isles alone, considerable as they have been, and great as they still are in some fields.

Estimates of mineral reserves must necessarily have no lasting character. Not only are they affected by extraction as it proceeds, but also they are profoundly influenced by changes in the economic situation, and by improvements in the technology of extraction and recovery. The waste of yesterday becomes the submarginal reserve of to-day and the ore of to-morrow. Perhaps, therefore, any estimate of workable resources is a little more pessimistic than it need be. If, however, it results in a stimulation of scientific effort in the search for new sources and in the development of improved technical methods, it will have served a useful purpose. K. C. DUNHAM

CHEMISTRY FROM THE SCHOOL TO THE UNIVERSITY

Chemistry for Matriculation

By Dr. G. H. Bailey and H. W. Bausor. Fourth edition, revised and rewritten by Dr. Dudley Ridge. Pp. iv + 487. (London: University Tutorial Press, Ltd., 1947.) 7*s*. 6*d*.

Chemistry for Schools

By C. Jenkins and E. H. Foinette. Part 3. Pp. vi + 254. (London and Toronto: William Heinemann, Ltd., 1947.) 4*s*. 6*d*.

Practical Chemistry

By John Lambert and T. A. Muir. Pp. xx + 383. (London: William Heinemann, Ltd., 1947.) 12*s*. 6*d*.

Fundamental Chemistry

An Elementary Textbook for College Classes. By Prof. Horace G. Deming. Second edition. Pp. xvi + 752. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 24*s*. net.

General Chemistry

An Introduction to Descriptive Chemistry and Modern Chemical Theory. By Prof. Linus Pauling. Pp. vii + 595. (San Francisco: W. H. Freeman and Co., 1947.) 4.25 dollars.

Chimie organique

Par Prof. A. Kirrmann. (Collection Armand Colin: Section de chimie, Nos. 246, 247.) 1: Chimie organique générale. Pp. 220. 2: Fonctions simples. Pp. 195. (Paris: Armand Colin, 1947.) 100 francs each vol.

DESPITE the revision by Dr. Ridge, "Chemistry for Matriculation" still gives the impression of being old-fashioned both in content and in presentation, although it will presumably meet the rather limited demand for this type of book. The reviewer believes that no text-book of chemistry can go through several editions over many years and still retain its initial appeal; after a time it is surely better to write a new book than to over-extend the useful life of the original.

"Chemistry for Schools", by Messrs. Jenkins and Foinette, the last of a trilogy, is intended to cover the final period of a course leading up to the school certificate examinations. To facilitate revision some of the ground covered in earlier volumes is treated again. It is pleasingly produced, and will be readily acceptable to schools where the earlier volumes are in use.

"Practical Chemistry", by Messrs. Lambert and Muir, is designed for students in the latter part of their school certificate course, and throughout their preparation for higher school certificate examinations and the First M.B. examination. To this end the three hundred experiments are divided into six sections. Physical chemistry is treated first, then inorganic chemistry on the basis of the Periodic Table, and organic chemistry subdivided into aliphatic and aromatic divisions. Volumetric analysis, which has previously appeared separately as "The Essentials of Volumetric Analysis", is followed by qualitative analysis based on ionic reactions, with organic reagents introduced for the confirmatory tests, and an introduction to gravimetric analysis. The book is completed by a section on elementary biochemistry. Each experiment is clearly described, together with a brief theoretical explanation, while the apparatus and chemicals required are listed. This book has been carefully compiled from the long experience of the authors, and is well produced. It should meet with ready acceptance as a comprehensive practical book for senior school work.

The two American texts are in pleasing contrast to the first three books, both for the quality of their production and for the refreshingly new approach to the subject. Whereas the former are limited by the school examinations system in Britain and are largely descriptive in character, in the latter much greater attention is paid to the theoretical foundations of the subject. There is no hesitation in introducing the atom and electrons at the earliest stage in a stimulating manner. These two books are introductory texts for a one-year course, and probably would be best used for students meeting the subject for the first time at sixth-form level or as a subsidiary subject at university level. Their prices compare unfavourably with the equivalent British texts, and make it unlikely that they will be widely adopted in Britain. Nevertheless, they can be recommended wholeheartedly to first-year university students.

Prof. Deming's "Fundamental Chemistry" differs from his "General Chemistry" and "Introduction to College Chemistry" in giving fuller treatment of the principles and less space to the historical, cultural and industrial aspects of the subject. In this edition the earlier chapters are simplified by presenting the internal structure of atoms in an elementary way and postponing the details of nuclear chemistry to near the end of the book, when the fission of uranium and plutonium and the creation of synthetic elements is considered. Inorganic complexes and silico-organic compounds are introduced to show that inorganic chemistry is not limited to acids, bases and salts.

Prof. Pauling is known to every university student for his outstanding achievements in theoretical chemistry and their application to problems in inorganic and organic chemistry and biochemistry. He will now reach a younger body of students through his introduction to theoretical and descriptive chemistry. After a discussion of the properties of substances, their atomic and molecular structure, and a survey of descriptive chemistry in relation to the Periodic Table, there are given thorough discussions of weight relations in chemical change, valence and electronic structure, and oxidation-reduction reactions. The first detailed chapter of descriptive chemistry deals with chromium, manganese, and their congeners. These elements are selected for this prominent place for the interest of their chemistry and as excellent examples of oxidation-reduction reactions. The remaining chapters deal with descriptive chemistry and theoretical topics, such as thermo- and radiochemistry. The text gains much from the unconventional diagrams by Roger Hayward, with their emphasis on structural and crystal chemistry.

In the two volumes by Prof. Kirrmann, organic chemistry is presented in pocket form, and the half-hour spent in cutting the pages open is well rewarded. These volumes are recommended to undergraduate chemists who wish to consolidate their knowledge of French. In the first volume general theoretical topics are developed, and the sections on structure and reactions well repay reading. The second volume introduces systematic organic chemistry without the conventional division into aliphatic and aromatic sections, the classification being on the basis of functional groups. The treatment of heterocyclic compounds is less satisfactory, being considered in a separate chapter in rather sketchy fashion. A further volume on multiply functional compounds is promised and will be awaited with interest.

S. H. HARPER

CHEMICAL PROMOTION OF ROOTING IN PLANTS

The Use of Auxins in the Rooting of Woody Cuttings

By Kenneth V. Thimann and Jane Behnke. (Maria Moors Cabot Foundation, Publication No. 1.) Pp. iii + 272. (Petersham, Mass.: Harvard Forest, 1947.) 1 dollar.

In 1937, the Maria Moors Cabot Foundation was established in the United States to "promote education in the art of increasing the capacity of the earth to sustain human life"; the growth and propagation of trees and other plants as a source of fuel and energy was to be a primary study, and its subsidiary purpose was "to disseminate information helpful and stimulating to others who may wish to enter this field of effort". The book under review, which is the first special publication produced by the Foundation, certainly serves this subsidiary purpose for one of the topics of study in wide-ranging investigations the results of which have been mainly reported in ordinary scientific journals.

Prior to resuming their experiments on vegetative propagation, the authors decided to collect and collate all available published data of a quantitative or semi-quantitative kind on the use of auxins in the promotion of rooting. Gratitude will be felt to them for publishing the results of their labours, which must have been considerable. In the bibliography there are 274 citations—about three times the number in Mitchell and Rice's summary in 1942. The publications cited report work done up to 1946 in a number of widely scattered countries but mostly in greater America. (The reviewer has failed to find any references to papers published in Scandinavia, France or Italy. Is this because interest in the root-forming powers of chemicals has not yet been aroused in these countries ?) Most of the reports are no more than a few pages long. Few of them can be considered as making, by themselves, solid contributions to scientific knowledge; but, read with other texts (for example, the appropriate chapters in Went and Thimann's "Phytohormones" (1937), and in "Hormones and Horticulture" (1947), by Avery *et al.*), the information collectively contained in them, assembled as it has been by Prof. Thimann and Miss Behnke, may well assist in the design of future experiments by plant physiologists who, working on ideas derived from those of Sachs and Beyerinck, seek to unravel the complexities of reacting systems which are competent to produce lateral and adventitious roots.

Up to the present, in this field practical control has outdistanced intellectual control. For the physiologist there may therefore be too little about too much in this book; but gardeners and foresters will find in it a mine of information to guide them in their efforts to establish the conditions which will, with surety, accelerate the rooting of cuttings from ornamental plants or from herbs, shrubs and trees of economic importance. The authors give accounts, ingeniously condensed, of five thousand trials on nearly four hundred genera, with species, varieties and hybrids of *Rhododendron*, *Prunus*, *Pinus*, *Picea*, *Citrus* and *Rosa* among those most used. In these trials, observations have been made of the influence on powers of quick rooting (taking a week or two) or of slow rooting (taking up to a year or more) exerted by one or more of twenty-one synthetic chemicals and sixteen commercial auxins (only one of British manufacture) applied in a variety of ways (basal dipping, coating, etc.) to different kinds of cutting (leafy and leafless softwood or hardwood, leaf, leaf-bud, etc.). Clearly the authors have disseminated much helpful and stimulating information.

M. THOMAS

SERVOMECHANISMS

Theory of Servomechanisms

Edited by Prof. Hubert M. James, Nathaniel B. Nichols and Assoc. Prof. Ralph S. Phillips. (Massachusetts Institute of Technology; Radiation Laboratory Series, No. 25.) Pp. xiv + 375. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 5 dollars.

IT is appropriate that one of the first major works to be published on the theory of servomechanisms is a product of Massachusetts Institute of Technology. The contributions during the past few years of both the M.I.T. Servomechanisms Laboratory and Radiation Laboratory to the theory and practice of automatic control are well known and highly respected by specialists in the subject, and this book, which is volume 25 in the Radiation Laboratory Series, will be welcomed universally. Notwithstanding the fact that there are ten contributing authors, the editors have arranged the mass of new material at their disposal admirably, and continuity in the development of the main ideas is maintained throughout. Several chapters include hitherto unpublished work. For example, a chapter is devoted to the conditions for stability of filter networks and control systems which are actuated by intermittent data; to the reviewer's knowledge no previous quantitative studies of these important systems have been undertaken.

The authors have been influenced in their treatment of the servo problem by modern electric filter design theory and communication engineering techniques. This is no doubt due to the nature of the servo design problem with which they were concerned during the War, namely, the design of automatic following radar equipment. In the development of such equipment the major problem is to minimize the effect of spurious misalignment signals, a problem which is analogous to that of increasing 'signal to noise' ratio in a communications system. An interesting method of dealing with such a situation is described by Prof. Phillips in Chapter 7. If the input 'noise' is assumed to be purely random and optimum performance of the system is assumed when the value of the root mean square error is a minimum, the method shows how optimal values for the control parameters can be obtained without the necessity of deriving the roots of high-degree characteristic equations; the method is illustrated by numerical examples.

The introductory chapter by Prof. Getting is excellent both in its conciseness and quality; it is, in fact, the best short introduction to the basic philosophy of servo system design known to the reviewer. Another valuable feature is the chapter devoted to the study of the behaviour of typical elements used in the design of control systems, such as error measuring devices, servo motors, power amplifiers and gear trains.

The chapter on general design principles introduces the Nyquist stability criterion, the concept of 'equalization' (for example, stabilization) of servo loops, and an elegant application of the attenuation (expressed in decibels) – log frequency and phase – log frequency diagrams to illustrate the frequency response characteristics of a control system and their use in the important problem of controller synthesis. In order to exemplify the power of these new theoretical techniques, a typical radar tracking control system is analysed in detail and, as a second example, the design of a low-power servo system incorporating a two-phase induction motor is discussed.

In view of the authoritative nature of the book it is perhaps somewhat disappointing that it is devoted exclusively to linear systems, especially since it is becoming increasingly clear that non-linear effects such as backlash in gear trains, static friction, saturation of amplifiers, resilience in shafts, etc., constitute the most important factors which limit the performance of modern servo systems. Admittedly, the difficulty of handling such problems is considerable and probably justifies their omission.

A minor criticism concerns the introduction of the problem of designing a manual control system in the last chapter. Despite considerable advances in the design of manual controls, it is unlikely that the transfer function of a human operator will be known with any accuracy for a considerable time to come. The assumption that an operator in tracking a target turns a handwheel at a rate proportional to the error which existed, say, 0·3 sec. previously, cannot be substantiated by experiment and can be misleading.

Atomic Challenge

A Symposium by Prof. J. D. Cockcroft, Prof. M. L. Oliphant, Group-Capt. G. L. Cheshire, Dr. J. Bronowski, Sir George Thomson, Capt. Cyril Falls, Prof. P. M. S. Blackett, Sir Henry Dale, Bertrand Russell, Sir John Anderson and Henry Wallace; with Commentaries by Students of Different Nationalities. Pp. x + 180. (London: Winchester Publications, Ltd., 1947.) 8*s.* 6*d.*

The talks on "Atomic Energy: the Present and the Future" which the British Broadcasting Corporation arranged during March last year, first in the Home Service and afterwards in the 'third programme', have now been published in book form. To them have been added a series of comments by younger men and women representing American, Russian, German and Chinese points of view, and the talk on atomic energy which was given by Mr. H. A. Wallace in the third programme of the British Broadcasting Corporation during his recent visit to Great Britain. While these comments are of interest as indicating the attitude of the younger generation to the problems which atomic energy presents, and in particular reveal a general readiness to face the sacrifice of national sovereignty involved in any scheme of control, they add very little to the substance of the symposium. Moreover, the comments are not very clearly distinguished from the actual talks: the reader who missed the actual broadcasts is left to identify them chiefly by the biographical notes. The titles of the broadcasts have been discarded, and the substitutes are scarcely an improvement on the originals. An equally important blemish is the omission of any indication as to the dates when the broadcasts were given; those who wish to study the actual broadcasts may well be better served by *The Listener* of May 13, 1947, in which the series was first published.

Annual Review of Microbiology

Charles E. Clifton (Editor), Sidney Raffel (Associate Editor), and H. Albert Baker (Associate Editor). Vol. 1. Pp. vii+404. (Stanford, Calif.: Annual Reviews, Inc., 1947.) n.p.

In the preface of this latest 'Annual Review' it is explained that a canvass of representative microbiologists indicated that their interests were not sufficiently covered by an already large number of periodical reviews covering at least many parts of the same subject. Time alone will show whether this opinion is justified. The term 'microbiology' may be taken to cover the whole physiology of organisms too small to observe without a microscope. It includes, therefore, morphology, biochemistry, genetics and all interactions with external environments of Protozoa, Bacteria, Fungi and so forth. Until recently, these subjects have been the concern of different groups determined by differences in technique, and undoubtedly this has led to a poor diffusion of knowledge of matters which are applicable to all groups. In some sections, however, this deplorable situation has been relieved by the publication of reviews in existing periodicals. Particularly this has been so in the chemical field, and it may now be doubted whether there is much ignorance of the biochemistry of one form of life among the students of another; at least in the particular field of biochemistry the student is interested in. It can scarcely become practicable for anyone to develop an abiding interest in many branches of a subject which has no biological limits. The present volume presents articles of widely diverse interest. The fractions of each subject covered are necessarily so small that the reader must still rely on the many reviews appearing elsewhere on practically the same field. Any of the articles could properly have appeared in existing reviews and, curiously enough, one of them has already done so. The articles which the reviewer is capable of judging are of a high order and presented with a personal touch which is valuable. Certainly an active worker must run his eye through this further addition to his survey of information, but he must not expect that this annual review alone is going to keep him abreast of developments.

Paul Fildes

A Text-Book of Practical Organic Chemistry

Including Qualitative Organic Analysis. By Dr. Arthur I. Vogel. Pp. xxiii+1012. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1948.) 42*s.* net.

Dr. Vogel's books on analysis are widely used in teaching practical inorganic chemistry. His new volume is intended as a comprehensive laboratory manual for students of organic chemistry. It gives a full and valuable description of organic chemical technique, details of preparation of more than six hundred compounds, and a scheme of qualitative organic analysis. There are appropriate notes on the preparative reactions described and on the properties of the various classes of organic compounds. A curious omission is the almost complete absence of reference to quantitative organic analysis. It seems to the reviewer that some practice at least in quantitative elementary analysis is of value in the student's training, even in these days when the fully fledged organic chemist hands his analysis specimens to the microanalyst for determinations which he is usually quite unable to carry out himself.

It is a little doubtful whether such an elaborate laboratory text-book will attract the average undergraduate student, who would certainly not wish to work through all the preparations described. It will have a greater appeal to teachers and research workers, although the almost complete absence of references limits its usefulness to these. The book is well produced and well illustrated, and the only error which has been noticed is in the structure assigned to hexamethylene tetramine.

J. W. Cook

The Right Way to Understand the Countryside

By Stanley A. Manning. (Right Way Books.) Pp. viii+116+4 plates. (London: Rolls House Publishing Co., Ltd., n.d.) 5*s.*

In attempting to provide information about "trees, shrubs and woodlands, wild flowers and plants (including fungi, mosses, etc.), insects, animal life, birds, countryfolk, customs and folk lore", as well as "information on the National Forest Parks, Youth Hostels Association, local clubs, research areas, etc.", in 113 pages, Stanley Manning might well have considered if he might not have made his book a little longer. He might also have considered whether the use of technical terminology is advisable in a book meant for beginners and whether the introduction of controversial issues should not be left to a later place than the first chapter. This is particularly so since anyone who reads right through the book will realize that Manning has much of value to offer to the novitiate in country ways and customs. The scraper-board drawings by Elaine Hancock are attractively done, but perhaps not so suitable as line drawings for a book of this kind.

T. H. Hawkins

ORIENTATION OF BIRDS ON MIGRATORY AND HOMING FLIGHTS

A GENERAL discussion on the "Orientation of Birds on Migratory and Homing Flights" was held at a meeting of the Linnean Society of London on May 13, the president, Prof. G. R. de Beer, being in the chair. A full report will appear in due course in the *Proceedings of the Linnean Society* (160, Part 2; 1948).

The opening speaker, Dr. W. H. Thorpe, discussed the extent to which the facts of bird migration and homing could be accounted for on the basis of known senses and sense organs. There are two aspects of the problem: (*a*) the ability of a migrating or homing bird to take up the right direction of flight, and (*b*) the ability to maintain a given direction once started even though unfamiliar with the territory and in bad visibility. Observations and theories dealing with the second aspect were discussed in detail. It was concluded that while we need to know very much more than we do about the extent of night migration in overcast weather, theories of visual orientation already go a very long way towards accounting for the known facts, and no other type of theory appears inevitable at present.

The ability of birds to take a correct initial direction of flight perhaps provides more difficult problems. This raises the question of the existence of some innate sense of direction, and in this connexion the recent work of Ruppell[1] on the movements of hooded crows (*Corvus c. cornix*) displaced from their normal migration routes was described. It was argued that these results provide good evidence for the ability of young hooded crows to maintain an approximately correct general direction of migration independently of the company of experienced birds and knowledge of the landmarks. This work, however, does not require the assumption of any mysterious sense of direction since this species migrates by day and the general direction may well have been maintained by a combination of time sense and orientation by the sun.

The work of Griffin[2] on the homing and migration of birds was then discussed, and it was pointed out that provided we assume that the bird is familiar with a considerable area of country around its nest and is not, therefore, homing to a restricted point, random radial scatter and very approximate spiral exploration might account for a very large proportion of the published experiments on homing. In this connexion the importance of obtaining evidence as to the actual course followed by individual birds when released in unfamiliar territory was stressed and the work of Griffin on the herring gull (*Larus argentatus*)[3] and gannet (*Morus bassanus*)[4] was described. It was pointed out, however, that there are some observations on the direction-finding of homing and migrating birds which seem at present inexplicable on the basis of known senses and sense organs, and that a careful search for other possible methods of orientation was fully warranted. Orientation by kinæsthetic receptors seems ruled out, and it was assumed that there is no satisfactory evidence for infra-red vision among birds. Finally, the recent work of Yeagley on the homing and orientation of pigeons was described and critically discussed. Yeagley[5] now claims to have shown that trained homing pigeons can navigate by correlating visual estimation of instantaneous land speed with sensitivity to the vertical component of the earth's magnetic field and to a Coriolis force. These two influences together form a navigational gridwork of two sets of lines. By this means the bird is supposed to be able to fly to its home, which is a unique point in the gridwork, or to a related 'conjugate point' existing in the gridwork at a position other than its home. Yeagley's first experiment, the 'magnetic wing' experiment, which the author regards as securing "positive though limited data for the electromagnetic phase of the theory", was criticized in detail by Dr. Thorpe and found quite inadequate as a basis for such conclusions. The rest of the 'evidence' produced by Prof. Yeagley consists of a series of experiments in which a total of more than five hundred pigeons were used. The method adopted depends on the fact that for any point in the eastern coastal States of the United States having a particular magnetic-Coriolis characteristic there will be one other, and only one other, 'conjugate point' having the same characteristics at a corresponding latitude somewhere in the Dakota–Nebraska–Kansas region. Thus "if a bird locates its home by navigating to the intersection of the proper magnetic vertical and the proper latitude he should as readily navigate to the conjugate point as to his home if released nearer the former". Pigeons were trained at State College, Pa., to return to a conspicuous mobile loft from up to seventy miles in various directions. Loft and pigeons were then transported to Nebraska and the pigeons released mostly at distances between twenty-five and seventy-five miles from the conjugate point. On the theory, it would be expected that pigeons should be able to home to the new locations as easily as to the old.

It was pointed out that the method of presentation adopted by Prof. Yeagley in his paper, and particularly his method of total flight vectors, was highly misleading. Moreover, two thirds of the birds used were lost during the course of the experiment —the results described referring to the remaining third only. Yeagley does not subject his data to any statistical analysis, nor are enough details given to enable any satisfactory assessment to be made by others; but such statistical significance as the results appear to possess may be accounted for by observational bias. The experiments involved transporting and setting up large mobile lofts which were rendered as conspicuous as possible in order to increase the chance of the pigeons finding them, although far less than 1 per cent of the birds succeeded in doing so. Thus, for 'returns' the experimenters had to rely on the birds being found and records sent in by pigeon fanciers, farmers and others up and down the country. It seems only reasonable to assume that large-scale experiments of this kind with the lofts set up in the region where the birds are expected to return were likely to attract a good deal of local interest and attention. Unless great care had been taken to prevent any information about the experiments becoming public, or to ensure that the birds were looked for equally intensively in the areas where they were not expected to appear, the results are open to great suspicion. No mention is made in Prof. Yeagley's paper of any precautions having been taken in this connexion, and so it must be assumed that they were not, in fact, taken. It is also unfortunate that there were no control releases of Pennsylvania-trained birds farther from the conjugate point. Thus, after careful examination of Prof. Yeagley's paper one is forced to conclude that no evidence has been produced that birds can navigate by a magnetic-Coriolis grid.

Dr. D. H. Wilkinson discussed recent theories of bird orientation which have invoked the use of Coriolis forces for determining latitude, and the vertical component of the earth's magnetic field for supplying the second co-ordinate. If a bird is to 'home' to within twenty-five miles at latitude 45° the effects by which it does this must be measured to an accuracy of about 0·5 per cent. The characteristics of home must, of course, also be remembered to the same accuracy.

The magnetic effect was discussed first. If the bird responds directly to a magnetic field, its problem is simply the measurement of it to 0·5 per cent. It is unlikely that birds have such a response, and it has been suggested by Yeagley that the potential difference induced by the linear translation of a conductor through the field may be detected. The first comment is that this potential difference would be unable to supply a current, and so the bird is called upon to make a purely electrostatic measurement of 10^{-5} volts per cm. of conductor to an accuracy of 0·5 per cent. These figures assume a bird flying at 40 m.p.h. at latitude 45°. The second comment is that there are present in the atmosphere potential gradients of the order of 1 volt per cm. These fluctuate widely and may change by several per cent in a mile. Even if there were no fluctuations the bird's problem would not be the measurement to 10^{-7} volts or so in 10^{-5} volts, but in 1 volt, an accuracy of 1 part in 10^7, not 1 part in 100. Such a measurement is impossible even leaving out of account the bird's necessity of knowing its air-speed accurately to 0·5 per cent. A second type of induction method which should be mentioned would consist in the rotation or oscillation, by the bird, of some conducting loop contained within its anatomy. Such a method gives a current of order $10^{-8}/R$ amp. for a loop of area 1 cm.^{2} and resistance R ohms oscillated with a period of 1 second. This method would remove the objection on the grounds of the earth's electrostatic field, the current due to this being of the order $10^5/R$ times smaller. Neither would the air-speed have to be known, though this would be replaced by a knowledge of the period of oscillation. The effect is again far too small to be considered, both in view of its absolute magnitude and of the existence of far larger natural currents in the bird's body. One therefore concludes that any measurement of the earth's magnetic field with the required precision is most highly improbable.

The Coriolis force is a sideways force experienced by a point which moves in a path the centre of curvature of which itself moves in a curve. It is then a purely geometrical effect, and has no explicit connexion with the rotation of the earth. It is only when the instantaneous rotation of the bird's flight is essentially that of the earth that the Coriolis force effects can be interpreted to yield the latitude. This means, in effect, that the bird must fly an extremely true course—and know that it is so flying. For the spurious Coriolis forces due to the inaccuracy of the bird's flight not to become comparable with those due to the rotation of the earth, the flight must have an instantaneous radius of curvature of about 100 miles or greater. This means a flight true to 1/50 in. in 100 ft., which is manifestly impossible. Though consideration of this fact alone is enough to show the impossibility of using Coriolis forces, the magnitudes are again far too tiny. As for the magnetic effects, there are two ways of using Coriolis forces, one crude and one refined. There is, indeed, close similarity in the analytical expression of the effects. The first suggestion to be considered is that of Yeagley, who supposed the bird to perceive the Coriolis force acting sideways on its body when in level flight. For our typical 40 m.p.h. bird this amounts to 1/6,000 g. As this force is no different in effect from the gravitational force, the only difference to the bird is that gravity now seems to act at a small angle to its true direction. The 0·5 per cent accuracy requirement means that this angle must be measured to about 0·2″ of arc. The bird has no idea where to measure this angle from, since gravity itself is not available, neither does gravity act at right angles to the earth's surface. In any event, if the bird's flight is not true to an extreme degree (the same order as remarked above) plain centrifugal force will exceed the Coriolis. The second suggestion came first in time, being that of Ising[6]. He considers the swirling motion of the fluid in an oscillating ring induced by Coriolis forces. Criticism has already been made[7] of the magnitude of the effects, which would be lost in the Brownian motion of the detecting organ. In any event, Ising's considerations are only of interest for a sitting bird because of the above remarks as to truth of flight. The conclusion, then, is that the Coriolis force is as useless as the magnetic field for bird orientation.

Finally, Dr. Wilkinson discussed the interpretation of homing experiments which seek to establish the existence of a double co-ordinate system. If a method such as Yeagley's 'total flight vector' be employed, the releases must not be symmetrical with respect to either of the co-ordinates or their normals through the point towards which flight is sought. If the homing then were only in one co-ordinate and the releases had such symmetry, the 'total flight vector' would point to the desired point, and no conclusion could be drawn as to the double co-ordinate homing.

The possibility that birds 'home' in one co-ordinate only should be seriously considered since the random search labour in which a bird is involved when it can home in, say, latitude only is enormously reduced. It may be that it is unnecessary to explain how birds 'home' to a point, but merely how they 'home' to a line. Such latitude homing may surely be accomplished with the aid of the sun-determination of its highest point to one diameter, giving latitude to thirty miles.

Prof. R. J. Wojtusiak, who had hoped to be present, had unfortunately to return unexpectedly to Poland. In his absence, Mr. H. W. Parker gave a brief summary of his paper entitled "Polish Investigations on Homing in Birds and their Orientation in Space"[8]. This paper summarizes the published work on the homing of wild birds, especially swallows and storks, hitherto carried out in Poland. Evidence was produced that visual recognition of landmarks plays a very important part in the homing orientation of swallows, and that once a homing flight from a particular locality has been accomplished, subsequent flights by the same bird over the same route will be performed at a much greater average speed. The possibility of infra-red vision as an aid to orientation was discussed and evidence brought forward[9] that the eyes of water tortoises are sensitive to infra-red. Similar experiments now in progress with pigeons were briefly mentioned, and it was claimed that positive results had already been obtained.

Dr. A. Landsborough Thomson pointed out that our ignorance of bird navigation is so great that we cannot afford to neglect any suggestions however far-fetched they may seem. He did not think that the suggestion that young birds migrating for the first time without their parents might merely have a tendency to go southwards towards the sun would carry us very far, since so much migration is not in the north-south line. He had no doubt at all that visual recognition plays a very large part in the orientation and migration of birds; but it does not, so far as we can see at present, give us a complete answer. Dr. Thomson agreed with previous criticisms of Yeagley's experiments, particularly because the birds were taken to the conjugate point and in some cases had been accustomed to that point before being taken to the release point. They should have been taken to the release point first.

Prof. V. C. Wynne-Edwards gave an account of his experiences with the release of herring gulls, and expressed agreement with the criticisms of Yeagley's work. He adhered to the view that in the end we shall find everything can be explained on a visual basis. He also suggested the possibility that the excellent time sense of birds might enable a bird to recognize a particular latitude by the time of sunrise.

Mr. James Fisher suggested that operating on a deliberate bias might be one of the methods by which birds can find their way in unknown country more efficiently than by theoretical spiral travelling. Thus if Lack and Lockley's famous shearwater released at Venice had operated on the principle of going along a right-handed coast it would eventually have reached the Bay of Biscay and thus presumably familiar territory.

Mr. B. W. Tucker agreed with the criticisms of Yeagley's experiments which had been put forward. But while much migration and homing can be explained in terms of visual responses, he felt that this cannot at present account for everything, and there are phenomena which are not completely explicable on the basis of any of the straightforward known senses. He pointed out that particular difficulties were raised by migration to oceanic islands and by the orientation behaviour of birds such as penguins.

Dr. M. H. Pirenne dealt with the subject of the sensitivity of birds' eyes and gave details of his experiments on owls and their response to infra-red rays. Discussing the work of Wojtusiak, Vanderplank and others, he pointed out various difficulties of interpretation and concluded that satisfactory evidence for infra-red vision is still lacking both in reptiles and birds. The fundamental difficulties raised by the infra-red radiation of the eye itself and associated tissues and by the infra-red absorptive power of the water in the eye were also discussed.

Mr. R. G. Newton suggested various possible methods by which the exact route taken by birds on release might be more easily traced.

MEDICAL RESEARCH DURING WAR-TIME

CRITICS of science, whatever their motives, have not neglected to make capital out of the destructive uses to which scientific results have been put by man; and critics of planned research, moved no doubt by purely scientific reasons, have vigorously asserted that planning hampers and may ruin the creative abilities of scientific men. To both these groups of critics the Report of the Medical Research Council for the years 1939–45, entitled "Medical Research in War" (Cmd. 7335. London: H.M. Stationery Office, 1947. Pp. 1–455. 7*s*. 6*d*. net), is to be commended. For in it the former will find a long record of beneficent uses to which scientific results have actually been put; and the latter will learn from it that planning, provided that it is wisely done by broadminded men who understand, and themselves experience, the mental processes and disciplines of scientific work, can produce both useful results and fundamental discoveries which advance the frontiers of knowledge. The proviso is a *sine qua non*; for planning that fails to recognize the basic individualism of scientific men and their kinship with artists imposes fatal limitations upon the research worker. The report is, for this reason, a tribute, not only to the men and women who have done the humane work that it records, but also to those who have, in their several ways, created and woven the themes treated, made the opportunities and provided the money and equipment without which the work could not have been accomplished.

The report, as its title implies, covers work done during the period of the Second World War. Military and industrial requirements, and also the health of the civil population therefore dominate its contents. The extent of the achievement recorded and the variety of the different, but often related, subjects investigated make it impossible, in a short review, to do much more than whet the appetite, so to speak, of potential readers and to invite them to read the report itself.

Apart from the information given about the composition and functions of the Medical Research Council and its committees, its arrangements for liaison with other men of science and scientific organisations in the United Kingdom, in other parts of the Commonwealth and in Allied countries, the names of its personnel, the publications of its research workers and the Council's own reports and a good deal of kindred information, there are fifteen sections which describe specific researches in considerable detail. These are summarized in a valuable "Introduction".

The subsequent sections deal with work on wounds and injuries; war diseases; therapeutics, including a useful account of the work on penicillin; war-time nutrition; personnel research done to increase the efficiency of the Fighting Services; health research in industry; special emergency services, such as blood transfusion, the emergency public health laboratory service in Britain and the supply of necessary immunological sera and antitoxins; the preparation and maintenance of biological standards of such substances as penicillin, vitamins A and E, heparin and certain serological reagents, together with the maintenance of the national collection of type cultures of micro-organisms; and a great deal of other work done either at the National Institute for Medical Research or elsewhere on a variety of subjects, of which the control of cross-infection in hospitals, the birth-rate, population trends, air-borne infection, the remarkable work on scrub-typhus and research on burns and scalds and applied psychology are a few examples. The report, in fact, amounts to a guide to the major trends of medical research in Britain at the present day.

The three main objectives of all this work have been: (1) the maintenance of the health of the Armed Forces and the civilian population, with special regard for malnutrition and the prevention of infectious diseases; (2) the restoration of the wounded and sick to full health; and (3) the creation of conditions which will ensure the highest possible efficiency, safety and comfort of fighting personnel and industrial workers in time of war.

The effort to attain the first of these objectives was very successful. Epidemic infective disease has always been a military menace, but during the Second World War it was reduced to military insignificance. In civil life it was also checked, although the common cold, influenza and a variety of industrial hazards remain and are recognized as urgent problems which are now being energetically investigated. The value of the nutritional work done during the War is so well recognized that it needs no comment here.

The success of the attack on the second objective is probably not fully appreciated outside the medical profession. Powerfully aided by the discovery of the sulphonamide drugs and the effects of penicillin, and by remarkable advances in surgical treatment, the work done in this field saved the lives and returned to useful occupation many men and women who formerly would have either died or would have survived only in helplessness and misery.

The story of the attack on the third objective is in some respects the most interesting part of the report. It includes accounts of the work on the physiology of flight at high altitudes and of deep-sea diving; the design of clothing for airmen and for life in arctic and tropical climates; the human problems associated with submarines and surface ships; the design of aircraft, guns and armoured vehicles in relation to the abilities and needs of the men who use them; and the special problems, physiological and psychological, arising from the use of complicated panels of instruments, engine controls and similar devices inseparable from modern mechanized warfare and industry.

As the report says, the main factor limiting the efficiency of a machine or weapon may be the human being using it, so that machines and weapons should not be designed by physicists and engineers without the co-operation of the psychologist, the physiologist and the medical man. To industry the same considerations apply. Lighting, heating, ventilation, noise, dust, toxic products of the factory—all these, as well as the relations between the machine and the people who use them, need scientific study if the best economic, social and humane results are to be attained.

During the period covered by the report the Medical Research Council has unhappily lost by death or retirement the services of men whose experience and creative ability were very valuable. The deaths of Sir Patrick Laidlaw and Sir Thomas Lewis, to whose influence and achievement the report pays tributes, were grievous blows. Although Sir Henry Dale retired after twenty-eight years of active service, he remained on the Council for four years longer, and his wide experience and outstanding ability are still happily available in consultation. Sir Edward Mellanby, secretary of the Medical Research Council, is fortunately still in office. He must be well satisfied with this record of the work to which he has devoted so much wise counsel and prolonged hard work.

G. LAPAGE

COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH, AUSTRALIA

ANNUAL REPORT

THE twentieth annual report of the Council for Scientific and Industrial Research, Commonwealth of Australia, covering the year ended June 30, 1946 (Canberra: Gov. Printer. *5s. 4d.*), now available, refers to the decision to establish a Division of Textile Research as a result of the visits of Mr. B. H. Wilsdon, Prof. J. B. Speakman, Dr. F. T. Peirce and Dr. A. C. Goodings mentioned in an earlier report; negotiations are in hand for the acquisition of a site for the headquarters laboratory at Geelong. Some work in the wool textile field will be undertaken by existing divisions.

The Building Materials Research Section and the Flax Research Laboratory came into existence during the year, and experimental work in nuclear physics and metallurgy was initiated in collaboration with the University of Melbourne. The Council has resumed its earlier practice of sending members of its scientific staff overseas to collect information on new developments and to acquire general experience in research and training in new techniques. A series of studentships is also to be offered each year to enable recent graduates of Australian universities to gain general research experience and training overseas in subjects related to the Council's programme of research, and then to return to Australia as members of the Council's staff. The Council's scientific liaison offices in London and Washington are now being maintained on a restricted basis to serve the peace-time needs of the Council.

With the end of the War, the Division of Plant Industry is devoting much more time to a study of pasture and weed problems, and the joint State and Council Weeds Co-ordination Committees are being revived. The North Australian Development Committee established by the Commonwealth Government and those of Queensland and Western Australia initiated a rapid examination, in the Katherine–Darwin–coast area, of the vegetation in relation to geology, soils and climate, the distribution, grazing and quality of stock, etc., during the 1946 dry season. Another committee on which the Council is represented, with the Waite Agricultural Research Institute and the Departments of Agriculture of South Australia and Tasmania, has been established to supervise investigations of dieback or 'gummosis' of apricots. Pasture investigations have included the management of *Phalaris* – subterranean clover and of Wimmera rye grass – subterranean clover in sown pastures, and a large-scale grazing trial of natural pasture in co-operation with the New South Wales Department of Agriculture. Mineral deficiency, pasture establishment under cover crops, various studies of mixtures of lucerne and *Paspalum sero-*

biculatum, and studies of cattle pasture and native legumes are also reported. Weed investigations have ranged over the control of galvanized burr, mintweed, capeweed in flax crops and studies of the action of plant poisons. Facilities for plant testing were re-organised and developed, some 510 species and varieties being received from abroad for trial during the year, while more than a thousand samples of seeds of Australian native and crop plants were sent to overseas agricultural and botanical institutions. Trials of introduced linseed varieties gave particularly promising yields, and linseed is believed to have good prospects as a commercial crop in southern Queensland. Experiments with the guayule rubber plant continued, and plants grown at Lawes under natural rainfall compared favourably in yield and rubber content with the best irrigated plantings in South Australia. Wheat investigations covered take-all disease. The study of fruit storage problems was again taken up, and work on the vitamin C content of tomato varieties continued. Trials with dichloroethylene and dichloroethane gave good results in the control of woolly aphis in propagating beds, and aspects of the dieback disease of apricot have been surveyed. Drug plant investigations have been concentrated on the study of *Duboisia* spp. as sources of hyoscine and atropine; the study of varieties of *Papaver somniferum* as sources of opium alkaloids; and the systematic search for sources of pharmacological and insecticidal substances in native plants. Vegetable investigations have included genetical work aimed at producing hybrids resistant to the potato viruses A, X, Y and leaf roll; agronomic studies of selected varieties of tomatoes; peas and beans; the use of zinc oxide as a disinfectant on cut potato setts; and spotted wilt of tomato.

Reports from the Divisions of Economic Entomology and of Animal Health and Production both give some prominence to trials with D.D.T. and 'Gammexane'. A preparation of the former, known as 'Rucide' and containing 50 per cent of the *pp*-isomer, which forms a stable fine emulsion when melted and poured into water, has given very promising results against cattle tick, in control of buffalo fly on dairy cattle and beef cattle, oriental peach moth, potato moth and cabbage moth and butterfly. D.D.T. has also given promising results in control of sheep blowfly. Other work by the Division of Economic Entomology has been concerned with the biological and clinical determination of D.D.T. and other insecticides, the biological control of cabbage white butterfly, citrus red scale, brown olive scale and potato moth, the insect control of St. John's wort, and insect vectors of plant viruses. The Division's work on wheat-storage problems terminated during the year; but promising results were obtained both with D.D.T. and '666' against hoppers and adults of the Australian plague locust. In the Division of Animal Health and Production, systematic epidemiological studies of mastitis were continued on the experimental herds of dairy cattle, and the good results obtained with penicillin in bacterial infections of the udder have been confirmed. Other investigations have covered toxæmic jaundice in sheep, contagious abortion of cattle and the toxicity of wheat for stock, while at the McMaster Animal Laboratory studies have been made of anthelmintics against *Hæmonchus contortus*, *Trichostrongylus* spp. and *Œsophagostomum columbianum* as well as of the administration of phenothiazine in salt lick and in small repeated doses, the effect of worm parasites on body weight and wool growth, external parasites of sheep and the blowfly strike problem. Biochemical studies have included the mineral metabolism of sheep and poisonous plants; studies in wool biology have included specifications of sheep types for wool production and histological studies of the sheep's skin. At the F. D. McMaster Field Station, studies have been made of the inheritance of skin wrinkles in sheep and of various faults and specific breeding groups. An investigation has been commenced into beef production in Australia, and an officer has been appointed for poultry breeding investigations.

The study of the nutritional physiology of ruminants has again been undertaken, particularly with the view of extending knowledge of the chemical, microbiological and physiological mechanisms involved in rumination and in the production of wool fleece, and the detailed study of the influence of protein intake on the latter has already indicated several broad principles. Other studies in the biochemical field have covered chronic fluorosis, the influence of deficiencies of minor elements, cobalt and copper deficiency and the effect of copper and cobalt dressings on grazing sheep. Soils investigations have been concerned mainly with problems in land settlement; surveys of various types have proceeded in five States. Considerable attention has been given to the place of soil investigations in research on building problems with particular reference to foundations, but lack of qualified research staff has hampered development. Irrigation settlement investigations at Merbein, Victoria, and Griffith, New South Wales, have proceeded on the usual lines, covering irrigation and drainage problems, soil moisture problems of irrigated lands, soil deterioration from irrigation, viticulture, fruit processing and vegetable agronomy.

In the field of forest products there has been a rapid transition from war-time problems to research on peace-time problems, and heavy demands from industry for assistance, particularly in connexion with housing, have been received when the Division concerned was short of staff through transfers. A feature of the year was the first Forest Products Conference, to which representatives from all the State forest services and from the Commonwealth Forestry and Timber Bureau and the Forest Department of the New Guinea and Papua Administration were invited. A major purpose of the Conference was to discuss programmes of work of the Division, the Division of Wood Technology of the New South Wales Forestry Commission and the Queensland Sub-Department of Forestry. Co-operation with the pulp and paper industry in the field of wood chemistry continued, and further work was carried out on lignin and pulp evaluation. The Timber Physics Section continued its work on wood–water relations and the physical properties of wood, while the Timber Mechanics Section, in addition to testing work, also made fundamental studies of the properties of wood, long-time loading and the strength and deflexion of floors. Work was also carried out in the Division on the development of building materials from wood products and other organic substances and on timber preservation, marine borer attack, fundamental factors affecting the penetration of preservatives under pressure, the diffusion of soluble preservatives into green timber, veneer and glueing, and the development and testing of adhesives.

Important changes have been made in food preservation investigations. All short-term investigations to maintain or increase the output of canned foods have been terminated to permit concentration on such long-term projects as the effects of maturity and variety on the quality of certain processed fruits and vegetables. Investigations on the storage of egg powder have been terminated, and work on the processing and storage of dehydrated vegetables curtailed; while studies on preventive measures for bacterial rotting in shell eggs have been resumed, as have some fundamental studies on the metabolism of fruit in cold storage and on problems of heat transfer and evaporation in cooling meat in refrigeration chambers. Other investigations have dealt with the organisation of the plant cell and its relation to cell stability and the respiration of the plant cell, particularly the organic acid metabolism and the nature of the oxidative enzymes, skin coatings for apples, the effectiveness of 'Pliofilm' wraps, 'stretch wraps' and case liners compared with a standard wax treatment for storing oranges. Features of the year's work on canning and fruit products were modified procedures for canned citrus juices, the canning of Freestone peaches, the steam-flow, hot-lid method of obtaining vacuum in commercial automatic can-closing machines and the maintenance of colour by addition of soluble tin to fruit packed in lacquered cans.

The exceptionally interesting report from the Fisheries Division refers to the return of the Division's research vessel from the Royal Australian Navy and the gradual resumption of research activities. The routine testing of the new southern trawling grounds with the Danish-seine net continued, and biological investigations covered Clupeoid fish, whitebait and *Tuna* species, salmon and mullet. Hydrological and seaweed investigations are also recorded, including both the production of agar and the use of seaweed as fodder; many aerial observations of pelagic fish were made from aircraft allotted by the Royal Australian Air Force.

The work of the Division of Electrotechnology has been devoted almost entirely to the establishment of the facilities required for the maintenance of standards and for measurements, and release of the staff of the Physics Division from routine testing has permitted further attention to research. Fundamental investigations on the physics of wool fibres, particularly in relation to their frictional properties, have been continued and extended to include studies of the ultimate structure of the fibres. Further work has been done with the view of maintaining the International Temperature Scale quite independent of secondary standards calibrated elsewhere, and an instrument has been developed for measuring the temperatures of estuarine muds and waters. Some work on solar physics has been commenced, and the nucleus of a section to work on the physics of solids has been established.

The Division of Aeronautics is now concentrating on more fundamental and long-range problems, turbine engine research being particularly prominent. The instability characteristics of flat and curved plates of both isotropic and orthotropic material have been investigated, and work on plywood plates subjected to end compression has been carried further. Preliminary work has been undertaken on tungsten-chromium alloys, and tests on the corrosion of the alloys of mock-up cooling systems by inhibited and uninhibited ethylene glycol has been continued with a coolant containing sulphonated gyro-oil as inhibitor. A study has been made of the mechanism of corrosion and film formation in aluminium and its alloys. In the Division of Industrial Chemistry the process devised for the preparation of chrome chemicals from chromite by an acid treatment reached an advanced stage in pilot plant, and pilot plant tests have also been undertaken on the chemical isolation of cerium, thorium and lanthanum compounds from monazite. A survey is being made of Australian ceramic materials, and the Physical Chemistry Section has continued its work on surface chemistry with particular reference to aspects affecting the flotation process for the separation of minerals. Corrosion in aircraft engine cooling systems and condenser tubes in power generating plant, the adsorption of surface-active agents from organic solvents, sugar-cane wax, the pilot-scale isolation of mannitol from the exudate of sugarwood, catalytic oxidation of ethylene to ethylene oxide and catalytic dehydration of 2 : 3-butylene glycol to butadiene, the loosening of wool from skins by sweating and with depilatories are among other problems which received attention during the year.

In returning to the study of fundamental problems, the Division of Radiophysics has placed emphasis on researches into the propagation of radio waves, atmospheric physics and vacuum physics. The Lubricants and Bearings Section, renamed the Tribophysics Section, has been concerned with the mechanism of boundary lubrication, surface damage and wear, silicones, surface-active compounds and mechanical properties, the deformation of metals by heating and cooling, deformation and recrystallization of duplex alloys and the electrolytic polishing of metals.

OBITUARIES

Sir George Newman, G.B.E., K.C.B.

GEORGE NEWMAN was born at Leominster, Herefordshire, on October 23, 1870. He was the second son of Mary Anna Pumphrey and Henry Stanley Newman, who for twenty years edited the Quaker weekly, the *Friend*. Sir George was educated at Bootham School, York, and the University of Edinburgh. He graduated M.B., C.M. in 1892 and proceeded to the M.D. in 1895, his thesis on leprosy qualifying for the gold medal. In the same year he obtained the Cambridge D.P.H. During 1896–1900 he was senior demonstrator in bacteriology and lecturer in infectious diseases at King's College, London, of which he was later to become a fellow. During 1900–7 he was medical officer of health of the County of Bedfordshire and of the Metropolitan Borough of Finsbury; and lectured on public health at St. Bartholomew's Hospital. He early acquired reputation as an energetic administrator, and published works on the bacteriology of milk, on the relation of bacteriology to public health and on infant mortality.

In 1907, Newman was appointed the first 'chief medical officer' of the Board of Education. With Sir Robert Morant, the permanent secretary, and his able colleagues, Dr. Eichholz, Dr. Ralph Crowley and Dame Janet Campbell, Newman built up the school medical service and extended its scope and opportunities. As a result, the mental and physical education of the children of Britain has improved beyond all comparison with the past. The years from 1900 to 1919 were years of strenuous endeavour, and were perhaps the most constructive periods of Sir George's life-work.

The First World War gave a new impetus to preventive medicine, and in 1919 Dr. Addison, president of the Local Government Board, appointed Sir George Newman medical officer of the Board. However, the Ministry of Health was established in June of that year and took over the functions of the Local Government Board, the National Health Insurance Commission and other health activities; Sir Robert Morant became its secretary and Sir George Newman its chief medical officer, retaining his position under the Board of Education.

Newman's main task at the Ministry was to consolidate and develop the health services which had been established by the Local Government Board. Having to deal with wide issues, he was content to exercise general direction of the whole service. He therefore allowed his senior medical officers full scope in their respective spheres of work, although he was always ready to discuss important questions and decisions with them. In addition to his heavy responsibilities as chief medical officer of two departments, Sir George Newman undertook much other work. During the War of 1914–18 he was chairman of the Health of Munition Workers' Committee, which survives as the Industrial Health Board; he promoted the cause of temperance as medical member of the Central Control Board (Liquor Traffic); and served on many departmental and other committees. He rendered great service to medical education, not only in his special reports—"Outline of the Practice of Preventive Medicine" (1919) and "Recent Advances in Medical Education" (1923)—but also as medical assessor to the University Grants Committee, as Crown nominee on the General Medical Council during 1919–39, and in his work for the British Postgraduate Medical School and the London School of Hygiene and Tropical Medicine.

Newman was an indefatigable worker, a fluent speaker, an expert diplomatist, a philanthropist, and a lover of books and medical history. In his writings and in his long series of annual reports of his department, adorned with pregnant phrases and quotations, he maintained the literary traditions of his predecessors, Simon and Buchanan. These reports exercised great influence upon the general public, impressing upon them the importance and value of public health. At various times he delivered the Yale, Linacre, Gresham, Halley Stewart and Heath Clark Lectures and the Harveian Oration. He retired in 1935.

Sir George received many honours. He was knighted in 1911, created K.C.B. in 1918 and G.B.E. in 1935. His honorary degrees included D.Sc.(Oxon.), D.C.L.(Dunelm) and the LL.D. of London, Edinburgh, McGill, Toronto, Glasgow and Leeds. He was also F.R.C.P.(Lond.) (1918), Hon. F.R.C.S.(Eng.) (1928), and honorary freeman of the Society of Apothecaries. He received the Bisset Hawkins Medal of the Royal College of Physicians in 1935 and the Fothergill Gold Medal of the Medical Society of London.

Short of stature, with abundant white hair and white moustache, Newman was a well-known figure in Whitehall. His conversation was vivacious and dramatic. He married Adelaide Constance Thorp in 1898, and with her lived a happy and secluded home life. Lady Newman died in 1946. Sir George died on May 26, 1948, at York, at the age of seventy-seven, after a long illness.

ARTHUR S. MACNALTY

Dr. George H. Pethybridge, O.B.E.

GEORGE HERBERT PETHYBRIDGE, for many years one of the leading personalities in plant pathology in Great Britain, died in his native town of Bodmin on May 23 at the age of seventy-six. Born in 1871, of a family well known in legal, medical and banking circles throughout Cornwall, he passed from Dunheved College, Launceston, to the University College of Wales, Aberystwyth. He took an honours degree in science in the University of London, and, after a short period as science master at Kingswood School, Bath, and elsewhere, proceeded to the University of Göttingen in 1897. Here he studied under Prof. Berthold and obtained his doctorate for a dissertation on the effect of inorganic salts on the development and structure of plants.

Returning to Britain, he joined the staff of the Science and Art Department in the Royal College of Science, Dublin. When, in 1900, this body was taken over by the newly created Department of Agriculture and Technical Instruction for Ireland, Pethybridge became the first head of the Seeds and Plant Diseases Division of the Department. During the next twenty-three years he carried out a long series of researches on diseases of potato, flax and other crop plants. It was mainly his work on potato diseases that gained him world-wide recognition, including the award in 1921 of the Boyle Medal of the Royal Dublin Society. One of his innovations was to establish field laboratories in areas where the diseases were most prevalent.

By his thoroughness, enthusiasm and rigorous experimental methods he greatly stimulated the study of plant diseases in Ireland and set a very high standard for those who followed him. He was, moreover, a keen field naturalist, and in 1905 collaborated with R. Ll. Praeger in an account of the vegetation of the district lying south of Dublin, while in 1910, with J. Adams, he published a "Census Catalogue of Irish Fungi".

On the change of government in Ireland, Pethybridge resigned his post, and shortly afterwards in 1923 he became mycologist to the Ministry of Agriculture and Fisheries and assistant director of the Ministry's Plant Pathology Laboratory at Harpenden. From then onwards his work was of an administrative rather than a research nature; but he played a large part in promoting research in plant diseases—notably into virus diseases of plants—and under his guidance intelligence work on plant diseases occurring in England and Wales was second to none. His long and valuable services were recognized by the award of the O.B.E. shortly after he retired in October 1936.

Pethybridge clung tenaciously to his ideals, perhaps even at times in the face of progress, but to the many who came under his influence he was a most generous, helpful and homely friend, a delightful correspondent and a wise counsellor, at work as well as by his fireside. His scientific writings bear the stamp of careful preparation and of the thoroughness that characterized his whole life: he gave and demanded the best and despised the shoddy. Shy and retiring by nature, he usually avoided public life and office, though he was persuaded to accept the presidency of the British Mycological Society in 1926. Among other activities he served the *Journal of Pomology* in an editorial capacity from 1936 until 1948, and it is a fitting and timely tribute that the current volume is dedicated to him.

W. C. MOORE

Dr. A. S. Corbet

ALEXANDER STEVEN CORBET was born on August 8, 1896; on May 16, 1948, he collapsed from heart failure after hurrying for a train, and died shortly after. He was educated at Bournemouth and University College, Reading, taking honours in chemistry. Afterwards he took the Ph.D. degree, and in 1935 his D.Sc. in biochemistry. He joined the staff of the British Museum (Natural History) in May 1939, after an already varied career which had included appointments as bacteriologist at the School of Agriculture, Cambridge, bacteriologist and entomologist to the Rubber Research Institute, Kuala Lumpur, F.M.S., soil microbiologist at the I.C.I. Experiment Station, Bracknell, and bacteriological work with the Water Pollution Research Board.

Wide experience, linked with a life-long interest in entomology, resulted, when Corbet was enabled to devote his whole energies to the study of the butterflies of the world, in an approach and a method of treatment such as had not before been applied to these popular insects. A particularly successful example of his work was his treatment of the common and very variable sulphur-yellow butterflies of the genus *Eurema*, which had been a happy hunting ground of the name-coining 'splitters' of earlier days. Another was his revision of the rather intractable species of the 'Blues' of the Oriental genus *Arhopala*. In his work on the latter genus he made use of the parallel variation of a number of species occurring side by side throughout the Malaysian sub-region in a taxonomically novel way; he succeeded in defining the island races of particular species by reference to the general characteristics of each island group, thus eliminating a great deal of rather repetitive descriptive matter. The same parallelism among island species also emerged clearly from his revision of the species of the genus *Euplœa*, a large group of butterflies which also had until then resisted many attempts by more orthodox methods to reduce them to order. In a few years he had, in fact, overcome most of the systematic difficulties which had hitherto dogged the attempts of less gifted students of the systematics of the oriental Rhopalocera. His results are contained in the new edition of his "Butterflies of Malaya", which he has left ready for the press. The collections he formed in Malaya are bequeathed to the nation.

During part of the First World War Corbet served with the Royal Engineers; in the Second World War he was seconded to the Pest Infestation Branch of the Ministry of Food, where he was able, among other things, to carry out research on the taxonomics of insect pests of food which has proved of direct economic value.

Corbet was a prolific writer who had the rare merit of not wasting words. Though his entomological work cannot now be rounded off, the results of his soil research in Malaya have already appeared in highly condensed form in a single slim volume, his "Biological Processes in Tropical Soils". As a colleague he was invaluable, his unassuming modesty cloaking a width of experience and interest, and a personality of great charm. N. D. RILEY

WE regret to announce the following deaths:

Prof. Alfred C. Lane, emeritus professor of geology at Tufts College, Massachusetts, president in 1931 of the Geological Society of America, on April 15, aged eighty-five.

Sir D'Arcy Thompson, C.B., professor of natural history in the University of St. Andrews, on June 21, aged eighty-eight.

NEWS and VIEWS

Geology at Newcastle-upon-Tyne:
Prof. H. G. A. Hickling, F.R.S.

PROF. H. G. A. HICKLING is to retire at the end of this session from the chair of geology at King's College, Newcastle-upon-Tyne, which he has held since 1920. During this period he has greatly extended his own work in some of the branches of geology to which he had earlier made contributions, and his students have shown that wide range of interest which is characteristic of him. Already as a lecturer at Manchester he had investigated the Old Red Sandstones of east Scotland, described the footprints of fossil reptiles, examined the variations of gastropods, studied the structure of fossil plants, the microstructure of coals and the stratigraphy of the Lancashire coalfield; the latter topics he made his own at a time when coalfield work was thought by some to be scarcely suitable for academic geologists. At Newcastle he has added much to our knowledge of coals, and especially (by his development of techniques of section cutting) to the understanding of 'vitrain'. He has fittingly combined an active interest in the economic problems of the north of England with a full appreciation of the necessity for less obviously useful studies: all this has been to the advantage of his students. His work was recognized by the award of the Murchison Medal by the Geological Society in 1934 and by his election to the Royal Society in 1936.

Dr. T. S. Westoll

DR. T. S. WESTOLL, who is succeeding Prof. Hickling in the chair of geology in King's College, Newcastle-upon-Tyne, has had a distinguished career in geology and vertebrate palæontology. Graduating in 1932 in the College to which he now returns, he commenced research on the famous fish fauna of the Permian rocks of that area. He was awarded a Ph.D. and a senior research award of the Department of Scientific and Industrial Research, with which he proceeded to University College, London, to work with Prof. D. M. S. Watson. During his three years in that position, he visited many of the principal museums in Europe and commenced the work to which he has since contributed most widely, namely, the further study of the Old Red Sandstone and its faunas, particularly in the north of Scotland. In 1937, with grants from the Geological and Royal Societies, he spent several months in the United States and Canada, visiting the principal universities and museums, and commencing stratigraphical and palæontological field-work in the Gaspé Peninsula, New Brunswick and Nova Scotia. The latter important work was interrupted by his election to a senior lectureship at Aberdeen, though not before it had led to important results both in the stratigraphy and palæontology of the Devonian and Carboniferous rocks of that region. In Aberdeen, field-work on the Old Red Sandstone of various areas of north-east Scotland, the Orkneys and Shetlands and on their faunas has been actively continued, along with investigations of the morphology and relationships of the various groups of fishes and the origin of tetrapod structures. This work has become of international repute. In 1941 the University of Aberdeen conferred on him the degree of D.Sc. In the following year Dr. Westoll was elected a fellow of the Royal Society of Edinburgh and a member of the New York Academy of Sciences. In 1947 he was invited to the Princeton Bicentenary Celebrations to participate in the conference on palæontology, genetics and evolution, and afterwards to the Paris conference on palæontology.

Chemistry at University College, Swansea : Prof. J. E. Coates, O.B.E.

THE pending retirement of Prof. J. E. Coates from the chair of chemistry marks the close of an important period in the history of the University College of Swansea, for, of the professors of scientific subjects appointed at the time of its foundation, he is the last remaining in the service of the College. After a brilliant career as student at Bangor, in London and at Karlsruhe, and distinguished service during the First World War in the Royal Naval Air Service, he was in 1920, when a member of the staff of the University of Birmingham, called to the professorship of chemistry at the newly established Swansea College of the University of Wales. It then fell to his lot to start, build up and maintain one of the major departments of the College, and the magnitude of his success in this arduous and responsible labour is demonstrated by the rapid advancement of the Chemistry Department to its present prosperous condition, and great service to the important industrial area in which it is situated. Under his direction, a foremost feature has been activity in research in physical chemistry, in which branch he was trained during his early investigations under the great masters, Ramsay and Haber. Among his studies while at Swansea have been the physical and chemical properties of hydrogen cyanide and its solutions. His past and present students, his colleagues and his numerous friends will all wish Prof. Coates many years of further fruitful activity.

Dr. C. W. Shoppee

DR. C. W. SHOPPEE has been appointed to the chair of chemistry in the University of Wales, tenable at University College, Swansea, in succession to Prof. J. E. Coates. Dr. Shoppee's earliest research work was carried out in 1923 at the Imperial College with Dr. C. K. Ingold and the late Sir Jocelyn Thorpe. In 1924, he accompanied Prof. Ingold to the University of Leeds, and in 1928, after having held an 1851 Senior Studentship, was appointed to the staff of that University. In 1939, he was elected to a Rockefeller Research Fellowship, which he chose to hold in the laboratory of Prof. T. Reichstein at the University of Basle. In 1944, he was appointed to a readership in chemistry in the University of London, tenable at the Royal Cancer Hospital (Free). Dr. Shoppee is distinguished for his researches on the mechanism and kinetics of tautomeric change, and for his work on the hormones of the adrenal cortex, which led to the establishment of the detailed structures of these physiologically important compounds. At the Chester Beatty Research Institute of the Royal Cancer Hospital (Free), he has applied his special knowledge of the microchemical and chromatographic investigation of natural products to the isolation and identification of the endogenous carcinogenic substances present in human tissues. In the steroid field, he has gained an international reputation, and his most recent work involves application of the new conceptions of the mechanism of organic reactions to the determination of chemical configuration in natural products, an ultimate aim being to illuminate the highly specific relationship between chemical configuration and physiological activity.

Engineering at University College, Swansea : Mr. L. J. Kastner

MR. L. J. KASTNER, of the Department of Engineering, University of Manchester, has been elected to the chair of mechanical engineering at University College of Swansea, which became vacant by the appointment in 1946 of Prof. R. N. Arnold to the regius professorship of engineering in the University of Edinburgh. Mr. Kastner took the Mechanical Sciences Tripos at Cambridge in 1934. Following a period of practical workshop training with Messrs. Davis and Metcalfe, of Romiley, he went to the University of Manchester to do research on internal combustion engineering, which led to the degree of M.Sc. In 1938, he was appointed to the staff of the Engineering Department at Manchester, and in 1945 became senior lecturer in the Department. While there he has been responsible for the advanced teaching in thermodynamics at Manchester and has also taken a large part in running the Engineering Laboratories. He has been actively engaged in research, more especially in the field of internal combustion engineering, and has published several original papers dealing with various aspects of this work. It is of interest to note that Mr. Kastner is now the third in the family line of university professors, his grandfather and father having in turn held the chair of French in the University of Manchester.

Department of Scientific Research, India

THE Government of India has created a Department of Scientific Research with effect from June 1. The Department will be in the charge of the Prime Minister of India, and Sir Shanti Bhatnagar, director of scientific and industrial research, has been appointed secretary and principal executive officer. The Department will take over the work of the Board of Research on Atomic Energy and the Council of Scientific and Industrial Research. The latter body, although attached to the new Department, will retain its unofficial character and will continue to function as before. The new Department will deal also with scientific advice to Government departments, *ad hoc* scientific research in universities and research institutions, research scholarships in applied scientific subjects, international scientific unions, scientific liaison offices, the Scientific Consultative Committee and such other subjects as may be transferred to it. The Department will co-ordinate the scientific activities of the other Ministries, and in this work it will be assisted by a co-ordination committee consisting of eminent men of science.

Engineers and the Community

In an address delivered at the annual luncheon on June 8 of the Institution of Gas Engineers, the president, Dr. Harold Hartley, made some interesting comments on the relation of the engineer to the community. The term 'engineering', he suggested, should be extended to cover all endeavour utilizing the processes of Nature or scientific knowledge for the benefit and pleasure of mankind. This wider concept of the functions of engineers would bring the professional bodies closer together and give them increased influence in public affairs. The professional institutions set the standard for their members, and they can use their influence to ensure that, in the struggle for economic development, the fundamental cultural freedoms are not sacrificed. They can see that conditions are created which will enable everyone to give of his best in his own particular field; they should strive after something of the character of the old craft guilds, with their care for the reputation of their craft and their members, but also with a deep sense of public service. Dr. Hartley's audience consisted largely of gas engineers, and he rightly emphasized his points by reference to their special branch of the profession of engineering. He referred to the spirit of tolerance and loyalty which has characterized the gas industry in the past, and expressed the belief that this state of mind would enable the industry to overcome the difficulties inherent in the fundamental re-organisation which nationalization of the gas industry in Britain will involve. The Institution of Gas Engineers as a corporate body represents a limited number of types of men with specialist knowledge who are accustomed to thinking along similar lines; they should not find it difficult to co-operate with other specialists concerned in different ways with the industry, and with them to solve the problems lying ahead.

Acta Crystallographica

Acta Crystallographica is a new journal of crystallography published for the newly formed International Union of Crystallography by the Cambridge University Press. It is intended to replace the former *Zeitschrift für Kristallographie*, which between the two World Wars had attracted most of the original accounts of crystal structure analyses. In scope, however, it is intended to be wider, and sets out to reassemble the crystallographic work now scattered through a great variety of journals, and to be the main journal for experts in crystallography the world over. Six numbers are to be issued annually at a moderate cost made possible through subsidies from Unesco, and from numerous research associations and industrial firms in Britain and the United States. The first number, published in March, contains six full-length papers and three short communications on structure determinations of organic and inorganic substances; together with notes and book reviews. The papers are clearly illustrated, and data and methods are set out in sufficient detail for assessing their reliability. Linked with this new publication will be periodic structure reports analogous to the seven volumes of "Strukturbericht" (1931–39) and also a second revised edition of the "International Tables for the Determination of Crystal Structure" (1935). The editor and co-editors are to be congratulated on so promising a first number of a new scientific journal which is really necessary.

World Power Conference

A two-day meeting of the International Executive Council of the World Power Conference has been held at Stockholm. Nineteen countries were represented: Australia, Austria, Belgium, Canada, Denmark, Finland, France, Great Britain, Hungary, India, Italy, Netherlands, New Zealand, Norway, Poland, Sweden, Switzerland, Turkey and the United States. The British delegates were Sir Harold Hartley, chairman of the International Executive Council and of the British National Committee of the World Power Conference, who presided; Mr. Harold Hobson, vice-chairman of the British National Committee and lately chairman of the Central Electricity Board; and Dr. A. Parker, director of fuel research, Department of Scientific and Industrial Research. It was announced that the Fourth Plenary World Power Conference in London will be held in July 1950 at the house of the Institution of Civil Engineers. The theme of the Conference was approved; it will be "World Energy Resources, and the Production of Power". The future activities of the World Power Conference were discussed, and tentative invitations were received from India, for a sectional meeting to be held in 1951 concurrently with the Fourth Congress of the International Commission on Large Dams of the World Power Conference; and from Italy and Switzerland, who may be the joint hosts at an 'Alpine' Sectional Meeting in 1952 or 1953. The Hungarian delegates suggested a 'Danubian' sectional meeting, to be organised jointly by the national committees of the Danubian countries, on a 'regional' basis. At the request of the Economic and Social Council of the United Nations—which has conferred consultative status upon the World Power Conference—consideration was given to the 'Fuels' and 'Power' Sections of the Provisional Programme of the United Nations Scientific Conference on the Conservation and Utilization of Resources, to be held in the United States in May 1949. It was announced that the first post-war Statistical Yearbook of the World Power Conference will be published shortly; it will contain data on resources and annual statistics covering the eleven years 1936–46. The next meeting of the International Executive Council will be held in Brussels during the first week of July 1949. The new edition of the booklet showing the names of national committees and representatives has been published; copies can be obtained upon application to Mr. C. H. Gray, secretary, International Executive Council, World Power Conference, 201/2 Grand Buildings, Trafalgar Square, London, W.C.2.

Cattle Health and Milk Production

The three Fison Lectures, made possible by the generosity of Messrs. Fisons, Ltd., are part of the educational programme of the Animal Health Trust and were delivered last May by Prof. L. Seekles, of the Veterinary Biochemical School, University of Utrecht. Prof. Seekles chose "Mineral Disturbances of Cattle" as the theme of his first lecture. Our food-producing animals have, he said, become physiologically artificial beings. Experiments carried out in his laboratory strongly suggest that the forced development of the cow as a milk producer causes over-activity of the pituitary gland. Discussing this idea in relation to milk fever, Prof. Seekles suggested that preventive measures against this disease should be designed to prevent over-development of the pituitary gland during pregnancy. The biochemical features of grass tetany and 'Utrecht abnormality of milk', which results in curdling of the milk of apparently healthy cows during transportation of their milk or when it is boiled, were also discussed. The second lecture, entitled "Gastro-intestinal Auto-intoxication in Cattle and Horses", included a discussion of Dutch methods of treating acetonæmia. Much attention has been recently given to treatment with potassium chlorate, which may be beneficial if the liver is not seriously damaged. Lactate therapy, practised since 1942, has also given good results. The third lecture dealt with the complex subject of real and conditioned deficiencies of trace elements. Evidence has been obtained that in many cases increased motility of the intestine, due to causes independent of the amounts of trace elements in the food, such as the intake of protein and other components of rank spring grass, nematode infestations and paratuberculosis, may cause decreased absorption of trace elements. Intravenous administration of radioactive copper salts had shown that the liver plays an important part in the accumulation of copper. No relation between grass tetany of Dutch cattle and the intake of manganese could be obtained, but significant differences between the manganese content of grass from different soils were noted, the more alkaline soils containing the least manganese.

Earthquakes Registered in New Zealand during February 1948

SIX strong earthquakes were registered by the seismographs in New Zealand during February 1948. They were on February 9 (2), 10, 14, 16 and 23, that on February 9 being felt in Anatolia (Turkey). In addition, eighteen local earthquakes were felt in some place in New Zealand during the month. The greatest intensity of any one of these was scale 5 (Modified Mercalli intensity scale) in the Cook Strait region of both islands on February 4, the epicentre being near lat. 40·95° S., long. 173·6° E., and depth of focus approximately 50 km. Earthquakes with scale 4 intensity occurred on February 9 in the Wellington and Wairarapa Regions, on February 18 in the Uruwera District and on February 29 near Lake Coleridge.

Union Catalogue of German Books and Periodicals

OWING to the scarcity of German books and periodicals published since the beginning of the Second World War, the Foreign Office has requested the National Central Library to compile a union catalogue of such of these publications as have reached the United Kingdom. A circular has been issued asking libraries and other institutions to co-operate by amending a check-list indicating their holdings. Anyone who is willing to assist but has not seen the circular should write to the National Central Library (German Union Catalogue), Malet Place, W.C.1.

Geophysics at Hamburg

AT Hamburg, the University Meteorological Institute, the Centre for Earthquake Research and the University Institute for Oceanography have been amalgamated to form the Geophysical Institute of the University of Hamburg. The address is now Hamburg 13, Rothenbaumchaussee 33. The new Institute is working under difficulties, and would welcome exchanges of geophysical publications.

Society for the Bibliography of Natural History

AT a general meeting of the Society for the Bibliography of Natural History held at the British Museum (Natural History) on February 28 the following officers were elected: *President*, Dr. J. Ramsbottom; *Secretary and Treasurer*, Mr. A. C. Townsend, British Museum (Natural History), Cromwell Road, London, S.W.7; *Committee*, Prof. F. Balfour Browne and Messrs. J. Delacour, W. N. Edwards, F. J. Griffin, Francis Hemming and C. Kirke Swann. It is hoped to revive the activities of the Society, which was founded in 1936, and it was announced at the meeting that a further part of the second volume of the Society's *Journal* is in the press. This consists of a bibliography of whaling by Dr. J. Travis Jenkins. The last part of the *Journal* to be published was Vol. 2, Part 3, issued in April 1946.

Research on Nematology

THE Institute of Agricultural Parasitology, Winches Farm, 395 Hatfield Road, St. Albans, Herts, formally ceased to exist as such on September 30, 1947. So far as plant-eelworm work is concerned, its place has been taken by a new Nematology Department of Rothamsted Experimental Station with the following scientific staff: Dr. T. Goodey (head of the Department), Dr. B. G. Peters, Dr. Mary T. Franklin, Mr. D. W. Fenwick, and Mr. J. B. Goodey. From June 30 this Department will be housed at Rothamsted Experimental Station, Harpenden, Herts. Winches Farm is continuing as a field station of the London School of Hygiene and Tropical Medicine, with Mr. J. W. G. Leiper as administrative officer.

University of Leeds

THE University of Leeds has received a further grant of £10,000 from the Worshipful Company of Clothworkers, making a total grant of £30,000 to meet the capital cost of the extension of the Textile Industries Department now in course of construction. The British Hat and Allied Feltmakers' Research Association has given £1,000 for research in the same Department.

The following appointments have been made: Dr. F. Henriques, lecturer in social anthropology; Mr. A. N. Greenwood, lecturer in electrical engineering; Mr. C. Kisby, lecturer in textile design.

Commonwealth Fund Fellowships

THE list of awards of Commonwealth Fund Fellowships tenable by British graduates in American universities for one year, beginning September 1948, includes the following: E. R. Andrew, Christ's College and Pembroke College, Cambridge, to Harvard University, in physics; J. R. G. Bradfield, Trinity College, Cambridge, to the College of Medicine, University of Illinois, in biology; S. L. Bragg, Trinity College, Cambridge, to the Massachusetts Institute of Technology, in engineering; Dr. Archibald Brown, University of Glasgow and Trinity College, Cambridge, to Yerkes Observatory, University of Chicago, in astronomy; Dr. C. A. Bunton, University College, University of London, to the College of Physicians and Surgeons, Columbia University, in biochemistry; Dr. G. M. Carstairs, University of Edinburgh, to Cornell University, in cultural anthropology; R. B. Hunter, University of Edinburgh, to Johns Hopkins School of Medicine, in medicine; Dr. D. O. Jordan, University of London and University College, Nottingham, to Princeton

University, in chemistry; A. M. Macbeath, Queen's University, Belfast, and Clare College, Cambridge, to Princeton University, in mathematics; G. D. S. MacLellan, Pembroke College, Cambridge, to the Massachusetts Institute of Technology, in mechanical engineering; J. H. Paterson, St. Catharine's College, Cambridge, to the University of Wisconsin, in geography; S. V. Perry, University of Liverpool and Trinity College, Cambridge, to the School of Medicine, University of Rochester, in physiology; R. W. Riddell, University of London, to Duke University, in medicine; Dr. G. A. Smart, University of Durham and University of Bristol, in medicine; I. G. Stewart, University of St. Andrews, to the University of Chicago, in economics; Dr. Alwyn Williams, University College of Wales, Aberystwyth, and University of Cambridge, to the National Museum, Washington, D.C., in geology.

The following have been appointed to Commonwealth Fund Fellowships tenable by candidates from the Home Civil Service: Philip Allen, Queens' College, Cambridge, of the Home Office; R. E. L. Cleaver, New College, Oxford, of the Ministry of Fuel and Power; T. D. Haddow, University of Edinburgh and Trinity College, Cambridge, of the Department of Health for Scotland.

Cambridge Summer Course in Food Science

A SUMMER course in food science will be held in the University of Cambridge, in co-operation with the Department of Scientific and Industrial Research, at the Low Temperature Research Station during August 30–September 11. The whole field of food science will be surveyed, with the view of suggesting the emphasis which should be placed on various aspects in the basic training of scientific workers for the food industries. A substantial knowledge of chemistry, and some knowledge of biology will be assumed. A detailed syllabus and form of application for admission may be obtained from G. F. Hickson, secretary of the Board of Extra-Mural Studies, Stuart House, Cambridge, to whom the completed application form should be returned not later than July 10.

International Holiday Centre

THE French Association of Scientific Workers is organising an International Holiday Centre at Morzine (Haute-Savoie) during July 15–September 1. Morzine, without being a fashionable holiday resort, is one of the beauty spots of the French Alps. It lies to the south of Thonon at a height of about 1,000 metres; and around it are ranges rising to about 2,500 metres. So far as hotels are concerned, the French Association of Scientific Workers can secure accommodation at 800 and 700 francs a day (including service and taxes). It has also secured some good camping sites, and is trying to make arrangements for a canteen. Bookings can only be made for whole weeks (from Monday morning to Sunday night) and for a minimum of two weeks; registration fee, 500 francs each person. Applications should be made as soon as possible to the Association des Travailleurs Scientifiques, Maison de l'Université Française, 47 Boulevard St. Michel, Paris 5.

Modern Applications of Liquid Fuels

A JOINT conference, arranged by the Institute of Petroleum and the Institute of Fuel, will be held in the University of Birmingham during September 21–23 to discuss "Modern Applications of Liquid Fuels". The president of the Conference, Mr. J. A. Oriel, will give an address on "The Place of Liquid Fuel in the British Economy"; subsequent sessions will be devoted to the discussion of papers circulated in advance on fuel oil in the steel industry, other metal industries, glass and ceramic industries; domestic heating; gas turbines for land and marine power purposes; agricultural drying processes; diesel engines; and oil for gas making. Further particulars can be obtained from the general secretary, R. W. Reynolds Davies, 18 Devonshire Street, London, W.1.

Announcements

THE Minister of Fuel and Power has appointed Dr. H. Roxbee Cox, at present director of the National Gas Turbine Establishment, to be chief scientist at the Ministry of Fuel and Power. Sir Alfred Egerton, professor of chemical technology at the Imperial College of Science and Technology, London, has accepted the invitation of the Minister to be chairman of the Scientific Advisory Council which will be set up to advise him on the scientific aspects of his statutory duties.

SIR NORMAN HAWORTH, Mason professor of chemistry and director of the Department of Chemistry in the University of Birmingham, retires at the end of the present session under the age limit. He is to be succeeded by Prof. H. W. Melville, professor of chemistry in the University of Aberdeen. Dr. K. Mather, head of the Genetics Department of the John Innes Horticultural Institution, Merton, has been appointed to the newly established chair of genetics at Birmingham.

MR. J. E. CUMMINS, formerly officer-in-charge of the Information Service of the Council for Scientific and Industrial Research, has been appointed chief scientific liaison officer for Australia in London. He expects to remain in the United Kingdom for about five years, and will direct the future work of the Australian Scientific Research Liaison Office.

AWARDS from the Daniel-Pidgeon Fund have been made by the Council of the Geological Society of London to Dr. J. S. Webb, who proposes to investigate the tin-tungsten mineralization in the Hercynian geosyncline as exposed in western Europe, and to Mr. W. S. McKerrow, who proposes to undertake a statistical investigation of the variation of the brachiopods from fullers' earth.

THE Council of the University of Sheffield has made the following appointments: J. C. Gilbert, senior lecturer in economics; A. Gilbert, lecturer in psychology; J. H. Davies and S. J. Langley, assistant lecturers in economics; Brian E. Heard, assistant lecturer in pathology; Peter Freeman, research assistant to the professor of engineering.

THE second annual exhibition organised by the Birmingham Branch of the Society of Inventors will be held in the Chamber of Commerce Building, Birmingham, during October 25–30. The object of the exhibition is to show manufacturers and members of the public new devices that have been produced during the year. Entries for the exhibition are accepted, both from members of the Society and from non-members. Anyone wishing to enter an exhibit, which must be either patented, protected or of registered design, should write to the secretary, Mr. B. Thornton Clark, 244 Stoney Lane, Yardley, Birmingham 25.

Amino-Acid Metabolism of Tissue Cells *in vitro*

EMPLOYING a technique which at the time was far from being perfect, we were able in 1941 to demonstrate the general importance of amino-acids in connexion with the maintenance and growth of tissue cells[1]. It was found that cystine occupies a key position among the amino-acids; if absent from a diet that contains all the other amino-acids, the cells cannot be kept alive, but die within twenty-four hours. The relative significance of the other amino-acids could not at the time be tested similarly, because of the imperfection of our technique.

The technique has now been improved. Practically normal growth of cells has been obtained in a synthetic medium on a basic diet consisting of groups of substances known empirically to be of significance to the whole organism, namely, amino-acids[2], the methylating system, the SH–SS system, the vitamins, choline, creatine and the C_4-acids functioning in the Krebs cycle. If amino-acids are lacking in this basic diet, it is impossible to keep the cells alive in the dialysed plasma medium for any length of time.

In order to gain information regarding the importance of the individual amino-acids in Rose's mixture, the following technique was employed. Control cultures were kept on the basic diet including the whole series of amino-acids: lysine, arginine, tryptophane, methionine, histidine, glutamic acid, aspartic acid, proline and cystine. Experimental mixtures were then prepared, leaving out the one amino-acid the significance of which was to be investigated. Fig. 1 illustrates the growth of myoblasts in the control mixture, and in the experimental mixture, which in this case had lysine omitted; the lysine deficiency caused only a slight reduction in the rate of growth as compared with that of the control. The same experiment on osteoblasts showed these cells to be much more sensitive to lysine deficiency than myoblasts (Fig. 2). Apparently this amino-acid is more essential to osteoblasts than to myoblasts.

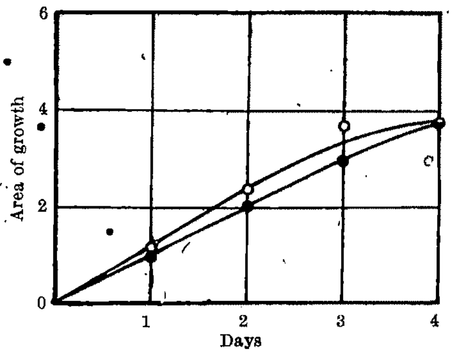

Fig. 1

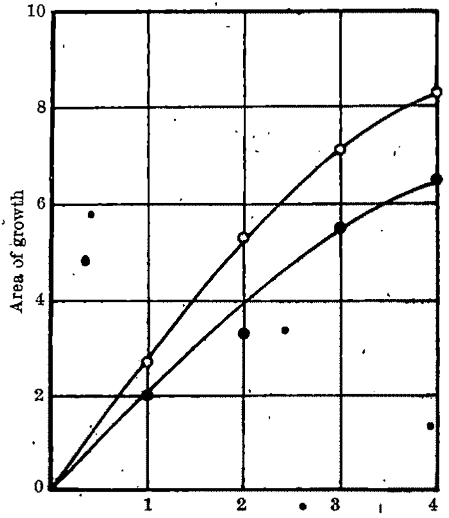

Fig. 2

Each one of the amino-acids mentioned above has been tested in our experiments. If graded according to the difference in growth between the control culture (in which the medium contains the complete set of amino-acids) and the experimental culture with one of the amino-acids omitted, the following sequence is obtained (Fig. 3).

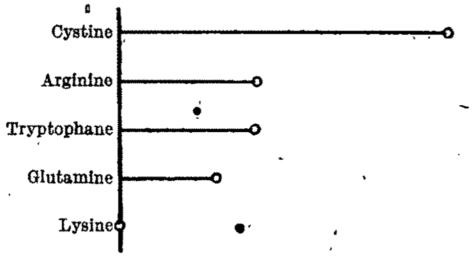

Fig. 3

It shows the difference in areal growth between control and experiment on the fourth day of cultivation caused by the omission of one of the amino-acids.

A more detailed account of the investigation will be published at a later date.

Absence of Correlation between Respiratory Inhibition of Plasmodia by Acridines and Antimalarial Action

THE suppressive action of 'Mepacrine' on the oxidation of glucose by *Plasmodium gallinaceum* has recently been described[1]. Since comparatively large concentrations of the drug (1 in 6,000) were necessary to produce an appreciable inhibition of respiration, it is questionable whether this effect is a measure of the specific antagonistic reaction responsible for the *in vivo* antimalarial properties of 'Mepacrine'.

More information on this point has now been obtained by comparing the inhibitory effects of the following acridines: 5-aminoacridine, 'Mepacrine' (2-chloro-7-methoxy-5-(δ-diethylamino-α-methylbutyl)aminoacridine), and the intermediate substance, 2-chloro-7-methoxy-5-aminoacridine. The accompanying table shows the action of these three acridines on the oxygen uptake of heavily parasitized, washed

COMPARISON OF EFFECTS OF ACRIDINES ON PLASMODIAL RESPIRATION, MAMMALIAN TOXICITY AND ANTIMALARIAL ACTIVITY

Compound	Mol. wt. of substance	% inhibition of oxygen uptake of *P. gallinaceum* (Conc. 1 in 6,000)	Toxicity; $L.D._{50}$, mice, subcutaneous (gm./kgm., base)	Antimalarial activity; quinine equiv. (*P. gallin.*)
5-Aminoacridine, HCl,H_2O	248	80·5 78·0 73·0	0·08	<0·02
2-Chloro-7-methoxy-5-aminoacridine (free base dissolved in acetic acid)	259	78·5	0·11	<0·06
2-Chloro-7-methoxy-5-(δ-diethylamino-α-methyl-butyl) aminoacridine, $2HCl,2H_2O$ ('Mepacrine')	508	38·6 44·4 43·3	0·28	2 to 6

chick red cells, suspended in buffered saline containing glucose. The concentration of acridines in the respirometer flasks was 1 in 6,000 of the compounds as tabulated. The toxicities to mice[2] and the antimalarial action *in vivo* against chicken malaria[3] are also included.

It will be seen that the *in vitro* inhibitory action of the less complex molecules is greater, weight for weight, than that of 'Mepacrine', and follows more closely the order of general systemic toxicity rather than the *in vivo* antimalarial action, which is in the reverse order. These results indicate that the observed inhibitory action of 'Mepacrine' on the respiration of the malarial parasite may represent the toxicity which high concentrations of acridines exert on living cells in general, but not the specific action of 'Mepacrine' on the malarial parasite.

Studies with Radioactive Penicillin

THE work of Gale[1] points to the possibility that penicillin may act by depriving sensitive organisms of glutamic acid, which is probably essential to their life. The present work was instituted to find out whether penicillin, by being itself adsorbed, blocks the passage of glutamic acid through the cell wall.

Whatever the mode of action of penicillin, it is to be expected that there would be a quantitative relationship between the amount of penicillin and the number of bacteria killed by it. Several workers have attempted to measure the amount of penicillin directly involved in the killing of a certain number of susceptible bacteria[2], but without success, as the amount of penicillin, if any, taken up by the organisms is too small to detect by biological methods. By using radioactive penicillin of a high specific activity, it should be possible to detect any uptake of penicillin by the bacteria.

For the preparation of the radioactive penicillin, we used 0·1 millicurie of S^{35} present in 0·014 mgm. of sulphur. This was diluted to a total of 0·109 mgm. of sulphur in order to give 2 ml. of broth in all. The medium used was based on that recommended by Jarvis and Johnson[3], modified by reducing the sulphur content to 0·0055 per cent, at which point sulphur became the factor limiting penicillin yield. After autoclaving, the medium was inoculated with a vegetative culture of the *Q* 176 strain of *P. chrysogenum* and was shaken for four days at 24° C. in a 50 ml. conical flask. After filtration, the penicillin was extracted from the cooled broth with ether and re-extracted into dilute phosphate buffer at *p*H 7·5. The solution was adjusted to *p*H 6, and 0·1 per cent of sodium hexametaphosphate was added to stabilize the penicillin[4]. The yield was 250 I.U. of penicillin, representing a 12 per cent conversion of the sulphur in the broth into penicillin with a specific activity of 0·05 microcurie per I.U.

It is perhaps noteworthy that the presence in the medium of 50 millicuries of S^{35} per litre did not adversely affect the growth of the mould.

The preparation of radioactive penicillin with a very much weaker specific activity has recently been reported from the United States[5], using 272 litres of broth containing 24·2 millicuries of S^{35}. They obtained 3·4 per cent conversion of the sulphur into penicillin with an activity of 0·00006 microcurie per I.U.

The radioactivity of the penicillin was measured by means of a Geiger-Müller counter, having a background rate of 14 counts per minute. The activity of a sample producing a counting-rate of 50 per minute could therefore be measured with an error of ± 3 per cent in a little more than an hour. Correcting for absorption of the radiations in the material of the sample, it was possible, in this time, to measure 0·004 I.U. of penicillin with an error of ± 5 per cent.

For the absorption experiments *Staphylococcus aureus* was grown on agar plates at 37° C. for 9 hours, scraped off, transferred in sufficient quantity to 25 ml. broth, so as to give a thick suspension, and incubated for a further 2 hours. A measured amount of radioactive penicillin was then added, and an aliquot portion of the suspension removed for radioactive assay; this removal of a standard volume of the suspension was repeated at intervals as a control. During the course of an experiment, these samples should give equal counts. After ½, 2, 6 and 24 hours, 5 ml. of the suspension was removed and filtered through a 'Gradocol' membrane and washed through with 2 ml. water into a graduated receiver. Aliquot portions of these filtrates were taken, dried on planchettes, weighed and counted. Any uptake of penicillin by the bacteria should be manifested by a decrease in penicillin concentration in the filtrate.

The accompanying table gives the results of an experiment in which 0·07 I.U. per ml. was employed in a suspension containing approximately $3·2 \times 10^9$ viable organisms per ml.; after 24 hours there were $0·24 \times 10^9$ viable organisms per ml.

Time (hr.)	Actual count per min. minus background		Count per 200 c.mm. per min. fully corrected		Penicillin units per ml.	
	A	*B*	*A*	*B*	*A*	*B*
0	36	42	49	48	0·068	0·067
½	33	41	45	48	0·063	0·067
2	31	37	43	43	0·060	0·060
6	41	40	43	46	0·060	0·064
24	36	36	47	42	0·066	0·059

A represents filtrates. *B* represents suspension.

From these results it is seen that the greatest difference between the penicillin concentrations in the filtrates is no greater than that for the suspensions; the latter difference represents experimental error.

Corresponding results were obtained from other experiments, where the penicillin concentration varied from 1 down to 0·05 unit per ml. From these experiments it is possible to say that absorption of penicillin, if any, probably amounts to less than ten molecules per bacterium.

The work is continuing, and further details of it will be published elsewhere.

We should like to thank Sir Alexander Fleming for his interest in this work, the Medical Research Council for the gift of the S^{35}, and Dr. W. F. Widdas for help with the construction of the counter.

Effect of Antibacterial Analogues of Vitamin K on *M. tuberculosis*

I would like to record some experiments made three years ago and recently repeated with a different technique. During a search for chemically defined growth-factors for *M. tuberculosis*, it was decided to investigate vitamin K. The role of vitamin K in bacterial metabolism has not been determined; but this vitamin is present in many organisms and is probably of nutritional importance[1,2,3]. Anderson has isolated from a laboratory strain of human tubercle bacillus a pigment, 'phthiocol' (2 methyl 3 hydroxy 1 : 4 naphthoquinone), which has vitamin K-like activity[4,5]. It has been postulated that phthiocol is derived from vitamin K_2 during the extraction of the bacteria[6]. For many years it has been known that *M. paratuberculosis* when freshly isolated will grow only on media containing extracts of other acid-fast bacteria, notably *M. phlei*. The claim has been made that phthiocol and 2 methyl 1 : 4 naphthoquinone can replace *M. phlei*[7]; but the stimulant action is not so marked, and hence it does not follow that the *M. phlei* growth-factor and these compounds are the same. *M. tuberculosis* var. *hominis* can also have its growth accelerated by extracts of other acid-fast bacteria, and for these reasons this investigation was undertaken. Reports in the literature on the action of phthiocol and 2 methyl naphthoquinone are not consistent[8,9], but naphthoquinone derivatives have been claimed as inhibitory[10]. In the accompanying table compounds 1 and 2 are water-soluble synthetic vitamin K derivatives and both inhibit growth.

Medium: Long's plus Tween 80, 0·01 per cent; bovine plasma fraction *V*, 0·2 per cent. Inoculum: 1 mgm. virulent *M. tuberculosis* var. *hominis*

Compound	Amount causing inhibition at eight days	
	Molarity	Parts per million
1 4 Amino 2 methyl 1 naphthol hydrochloride	10^{-5}	3
2 Tetrasodium 2 methyl 1 : 4 naphthohydroquinone diphosphate	4×10^{-4}	166
3 Quinoxaline di N-oxide	2×10^{-4}	33
4 2 Methyl quinoxaline di N-oxide	5×10^{-4}	80
5 Methyl pentyl quinoxaline di N-oxide	10^{-4}	25
6 2 Hydroxy quinoxaline	5×10^{-2}	1000
7 1 : 2 : 3 : 4 : Tetrahydrophenazine di N-oxide	2×10^{-4}	20
8 1:2:3:4 :Tetrahydrophenazine	5×10^{-4}	100
9 Phenazine mono N-oxide	10^{-4}	25
10 Phenazine di N-oxide	5×10^{-6}	1
11 Dihydroxy phenazine di N-oxide (iodinin) (impure preparation)	10^{-5}	2

As recently isolated virulent strains of *M. tuberculosis* require complex media of unknown composition, an indirect approach to the problem was sought by the use of antibacterial analogues of the vitamin K series. Such compounds have been made by McIlwain[3], and their effect is shown in the table. The results are parallel to those obtained with other organisms, and I have obtained similar but not identical results with different culture substrates. The phenazine derivatives are of interest because of their relation to the bacterial pigments pyocyanine and chlororaphin, and iodinin itself is obtained from *Chromobacterium iodinum*. Compound 10 is non-toxic to guinea pigs and mice, and *in vivo* tests are now in progress.

Thus the original hypothesis that vitamin K-like compounds are necessary for the nutrition of *M. tuberculosis* has not been proved; but the results listed do suggest that similar substances play some part in the metabolism of the organism. Recent advances in vitamin K research may have an application to this problem[11,12,13].

This work has been helped by a grant from the Medical Research Council.

Dicumarol Poisoning and Vitamin K Deficiency in Relation to Quick's Concept of the Composition of Prothrombin

In 1943, Quick[1] published some experiments which were taken as evidence for the multiple nature of prothrombin. In the same paper Quick expressed the opinion that the hypoprothrombinæmia in vitamin K deficiency might be due to the disappearance of the same constituent of prothrombin as that which is lacking in dicumarol poisoning, namely, the component which is relatively stable during storage.

Shortly after the appearance of the above-mentioned paper, I carried out a few simple experiments in order to establish whether these two forms of hypoprothrombinæmia are due to the lack of one and the same factor, as suggested by Quick.

The experiments consisted in mixing the plasma from vitamin K – deficient chicks with plasma from chicks poisoned with dicumarol and determining the clotting time by the addition of diluted chicken thromboplastin. If the components lacking in the two kinds of plasma were different, suitable mixtures of the plasmas should clot almost as fast as normal chicken plasma in the circumstances chosen. This was not found to be the case, the clotting times of the mixtures lying largely in the interval between the clotting times of the two different plasmas.

Recently, Quick[2] has elaborated his hypothesis on the nature of prothrombin further, and now claims that the relatively stable component consists of two factors. He suggests that dicumarol poisoning is concerned with one of these factors and vitamin K deficiency with the other. The simple experiments mentioned above show that a difference between the two forms of hypoprothrombinæmia cannot consist *merely* in the absence of one factor in dicumarol poisoning and of another in vitamin K deficiency in such a way that the clotting anomaly will be compensated by mixing the two plasmas.

Chemical Breakage of Chromosomes

IN a paper under the above title, Darlington and Koller[1] have analysed the close similarity between chemical and radiation-induced breakage of chromosomes, and have rejected the physical 'target' theory of the X-ray phenomenon as propounded by the late Dr. D. E. Lea[2]. First, they criticize the data on which this theory was based, asserting that "temperature control has been largely dispensed with in the experiments used by Lea as evidence"; and secondly, they conclude that "it is scarcely possible to doubt that both X-rays . . . and chemical breakage are immediately determined by chemical processes which in the X-ray case intervene between an ionization and breakage". In fairness to Lea, we feel that we should point out that neither of these statements is a valid criticism of the target theory. The effects of temperature on radiation-induced breakages have been taken into consideration, and it has been almost axiomatic among physicists that chemical processes follow on the initial act of ionization.

Sax[3] demonstrated that the yield of structural changes during X-irradiation is dependent upon the temperature of the material at the time of exposure, but is independent of the temperature before and after the exposure. Experiments by Lea and Catcheside, which will be reported in detail elsewhere, corroborate this result. Flowering shoots of *Tradescantia* were maintained at the same constant temperature before and after irradiation with X-rays and were irradiated at temperatures between 1° and 30° C. Fixations of dividing pollen grains were made at a series of times subsequent to irradiation. By this means the frequency of structural changes in relation to the rate at which mitosis proceeded after different treatments could be followed. The highest yield of structural changes was observed in the material irradiated at the lowest temperature; but the rate at which mitosis proceeded when the shoots were restored to their standard temperature after irradiation was independent of the temperature at which they had been irradiated. On the other hand, if the shoots were kept at a high temperature in the period after irradiation, mitosis was speeded up, so that the irradiated cells took a shorter time to reach metaphase; but the final yield of structural changes was not affected. This latter effect was recognized by Darlington and La Cour[4], who, however, did not observe the dependence of yield on the temperature during the irradiation.

Giles[5] irradiated *Tradescantia* pollen grains with neutrons, and found that two-break structural changes were independent of intensity. With X-rays such structural changes are less frequent per unit dose at lower intensities. This result with neutrons shows that breakage is almost instantaneous, and affords clear evidence that breakage occurs inside the ionization track. The observation with X-rays that either a lower temperature during irradiation or a higher intensity favours new unions as against old unions (restitutions), even though the treatment occupies only a few minutes, shows that the rearrangements are mostly completed within a short time of the irradiation.

That chemical processes form part of the sequence of changes which occur between an ionization and its biological effect was stated explicitly by Crowther in his Silvanus Thompson Memorial Lecture ten years ago. Discussing the target theory, he said, "the majority of upholders of the target theory would tend to look to chemical action as the first link in the chain"[6]. The point at issue is not whether chemical changes are involved or not, but where these changes start[7]. In the case of chromosome breaks, Lea's theory postulates that they must start inside, or within a few millimicrons of, the track of a single ionizing particle[8]. This conclusion was based on analyses of the relationship between the number of chromosomes affected and the dose of radiation administered, of the effect of varying the dosage-rate of the radiation, and of the effects produced by different types of radiation. It provides a satisfactory quantitative prediction of the biological phenomena under each of these headings. Recent work by Weiss[9], based on the hypothesis that ionization in an aqueous medium releases free hydrogen and hydroxyl radicals, shows that, quantitatively, the phenomena are consistent with interaction of hydroxyl radicals with large 'receptor' molecules: but an investigation by Lea[10] of the kinetics of the recombination of hydrogen and hydroxyl radicals led to the conclusion that the chemical effects of α-particles would be confined to the immediate vicinity of the α-ray tracks, though a rather wider range might be possible with X-rays. So far, the chemical approach has provided no specific mechanism by which hydroxyl radicals produced by ionizations outside the range postulated by the target theory could cause the observed biological changes in the same quantitative way. Until it has done so—and many workers in this field believe that it ultimately will—the target theory must be retained as the most satisfactory working hypothesis of the origin of the phenomena.

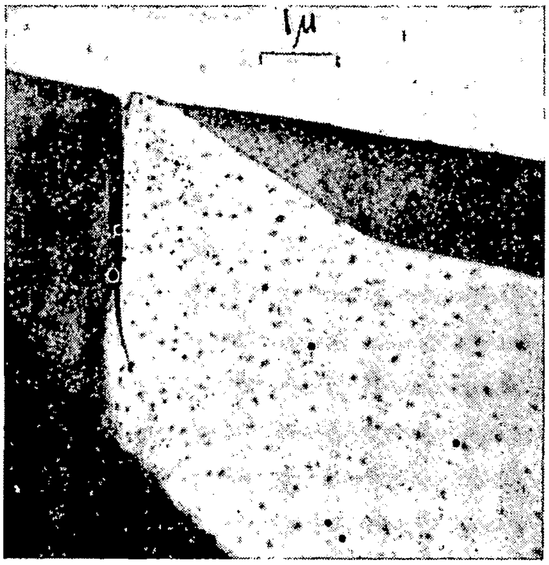
Electron Microscopy of the Sarcolemma

STRIATED muscle fibres are surrounded by a delicate membrane or sheath, the sarcolemma. It has frequently been stated[1,2,3] that this sheath is composed of a network of collagenous or reticular fibrils, arranged like a knitted sock. One of us (R. B.) in an investigation to be described elsewhere has failed to find any evidence of fibrillar structure using various methods of microscopy, including phase contrast and dark-ground illumination. We have, therefore, investigated the structure of the sarcolemma by means of the electron microscope (R.C.A. console model).

Frog's thigh muscles were teased roughly and allowed to soak for periods of up to a few hours in Ringer's solution. This produces numerous retraction clots in the fibres, leaving clear areas of empty sarcolemma. The fibres were then fixed or treated with various chemical reagents and dried in a desiccator. Unfixed fibres were also examined. After drying, the fibres were mounted on the usual 200-mesh specimen grid of the electron microscope. The accompanying photograph shows a strip of sarcolemma (formalin fixed) × 11,000 (initial magnification in microscope 5,000 times). No fibrils were seen at magnifications up to 25,000. The main feature is the presence of numerous small spots, of the order of 0·04–0·1 μ in diameter. In places where the membrane has become folded it appears that the spots lie *on* the membrane rather than *in* it. In some cases the spots seemed to form a more or less regular pattern, but this may not always appear to be the case owing to distortion of the membrane. The spots were seen in unfixed material, but were clearer after formalin fixation. Sheets of membrane were often observed to split under the action of the beam; the membrane tears linearly and cleanly without leaving fibrous strands, in marked contrast to high-polymer membranes which have frequently been studied by the electron microscope.



The nature of the spots is at present unknown. They are not seen in specimens which have been treated for some hours with dilute citric acid. It is possible that they might be points of attachment of either connective tissue fibrils or myofibrils. They are usually about 0·5 μ (or less) apart, a distance which does not correspond to any known periodicity within the myofibril; but it is possible that the sarcolemma has become shrunk or distorted by drying. The thickness of the sarcolemma is usually given as 1 μ. Electron microscopy suggests that it may be less than 0·1 μ, though a tenfold shrinkage is not ruled out.

These experiments are still in an early stage. The work is being continued with improved technique and a more detailed account will appear elsewhere.

We wish to thank the Ministry of Supply for the facilities which enabled us to carry out the investigation.

Capillary Distribution in Cow Skin

IN studies on the nature and distribution of the 'sweat' glands of Ayrshire cows, shortly to be published in detail elsewhere, a close relationship has been found between the distribution of blood capillaries and hair follicles.

Other workers[1-3] have been concerned with all or some of the following structures, (1) the hair follicle, (2) the sebaceous gland located near the middle of the hair follicle and opening into it, (3) the arrector pili muscle and (4) the 'sweat' gland lying at the base of the hair follicle and with independent duct opening on the surface of the skin close to the point of emergence of the hair. The number of hairs has been used as an index of the number of 'sweat' glands in different regions of the skins of buffaloes, Zebu, Formosan and Freisian cattle[1].

These structures appear to form a unit, and in our observations on twenty-one different skin regions of each of five four-year-old Ayrshire cows, we have been unable to find any one of these structures not associated with the others. This also applies to

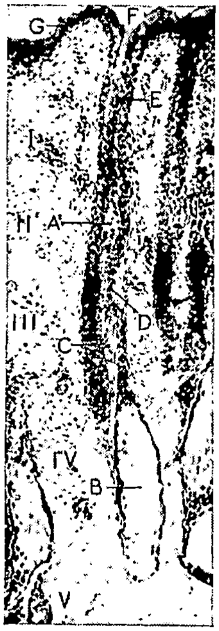

Fig. 1. VERTICAL SECTION OF CALF SKIN IN THE FLANK REGION. × 80. DELAFIELD H.-E. STAIN

A, sebaceous gland; *B*, 'sweat' gland; *C*, hair follicle; *D*, arrector pili; *E*, 'sweat' gland duct; *F*, emergence of hair; *G*, epidermis.

I, sub-epidermal level; II, sebaceous gland level; III, sub-sebaceous gland level; IV, 'sweat' gland level; *V*, sub-'sweat' gland level

the calves and embryos we have studied. The number of hairs per unit area of skin surface may therefore be taken as a direct index of the number of any of these four structures per unit area.

Cow skin may be divided into two distinct layers: the epidermis and the corium. In the corium the following five levels may easily be identified: (1) the sub-epidermal level roughly corresponding to the papillary layer and uppermost portion of the reticular layer of human skin, although in cow skin papillæ are generally absent and when present are not so prominent as in human skin; (2) the sebaceous gland level; (3) the sub-sebaceous gland level; (4) the 'sweat' gland level; and (5) the sub-'sweat' gland level. The latter four levels are all in the reticular layer. These levels and the structures referred to are shown in Fig. 1.

In the sub-epidermal level fine-calibre capillaries anastomose to form a network each loop of which encircles a hair follicle as seen in Figs. 2 and 3. This network is located in a position similar to that of rete subpapillare in human skin. In the sebaceous gland level this does not occur, though capillaries or fine arterioles running from the sub-sebaceous gland level almost vertically to the sub-epidermal level supply the sebaceous gland through fine branches. In the sub-sebaceous gland level and in the 'sweat' gland level the capillaries surround groups of two or more hair follicles, as seen in Fig. 4. In the sub-'sweat' gland level arterioles and venules are found but are few in number.

Fig. 4. 'SWEAT' GLAND LEVEL OF COW SKIN. FOREHEAD REGION. × 40. *D*, 'SWEAT' GLAND. OTHER DATA AS IN FIG. 2

Since every hair follicle possesses a capillary loop, in the sub-epidermal level the number of capillary loops is directly related to the number of hair follicles. According to our microscopic counts for one of these cows, the number of hair follicles per sq. cm. of skin surface was 940 ± 73 in the sacral region of the back and 3,000 ± 255 in the lateral region of the neck. The average diameter of the capillaries associated with each hair follicle in the sub-epidermal level was 0·086 ± 0·030 mm. for the sacral region of the back and 0·040 ± 0·005 mm. for the lateral region of the neck. The average circumference of the capillary loops was 1·043 ± 0·255 mm. for the sacral region of the back and 0·758 ± 0·089 mm. for the lateral region of the neck.

The capillary surface per sq. cm. of skin surface in the sub-epidermal region may be calculated by means of the equation:

$$S \doteq \frac{\pi dC}{2} \times n,$$

where S is the capillary surface per sq. cm. of skin surface, d is the average diameter of the capillaries, C is the average circumference of the capillary loops and n is the number of hair follicles per sq. cm. of skin surface in the chosen region. Since πdC is the capillary surface area of the whole loop, the area of the loop associated with one hair follicle (because of loop sharing) is $\pi dC/2$.

Hence the capillary surface per sq. cm. of skin surface may be calculated to be 1·33 sq. cm. for the sacral region of the back and 1·43 sq. cm. for the lateral region of the neck.

These calculations, of necessity, make no allowance for distortion during histological preparation or for physiological variation during life.

Hairs in the same skin site generally slope in one direction and the hair follicles incline to one side, forming an acute angle with the epidermis. The arrector pili muscle, the sebaceous gland and the 'sweat' gland are located in the obtuse angle. Hence, when the arrector pili muscle contracts, as in conditions of external cold, pressure will be exerted on the capillaries. This will probably supplement cutaneous vasoconstriction under such conditions and the peripheral blood flow will be reduced with consequent increased heat conservation. This function of the muscle is additional to its function in increasing heat insulation by the erection of hair. In human skin this latter function adds little to heat conservation but the capillary constriction effect may yet remain.

These studies form part of a project on the acclimatization of dairy cattle being undertaken at this Institute.

Relation of Enamel Protein to Dental Caries

I MADE some observations on the nature of enamel protein in 1936 [1]. The possible role of enamel protein in the production of caries is described below.

(*a*) Micro-analysis of enamel protein (Weiler) gave N 12·1 per cent, S 1·2 per cent; other nitrogen determinations (Schoeller) were 9·2 and 11·1 per cent. Levene[2] gives nitrogen determinations for mucoproteins as ranging from 6·7 to 13·3 per cent; nitrogen values for proteins are generally accepted as 12–18 per cent.

(*b*) Sections of developing human enamel stained with thionin provide evidence of limited value of the presence of material resembling mucin. Wassermann[3] has illustrated the secretion of globular material by the enamel-forming cells, the ameloblasts, in guinea pigs.

(*c*) A substrate resembling chondroitin sulphuric acid by qualitative tests has now been prepared from dentine by the use of calcium chloride[4]. Dentine is reduced to powder by the use of a dental engine and a bur, defatted with acetone and ether, and extracted with 10 per cent calcium chloride; the extract is deproteinized with a chloroform – amyl alcohol mixture and centrifuged. Chondroitin sulphuric acid is separated from the supernatant liquid by alcohol and glacial acetic acid, then washed with alcohol. A solution of chondroitin sulphuric acid prepared in this manner reduced Fehling's solution, and was not fermented by yeast. No pentose was detected; naphthoresorcinol gave a brown to purple colour; phloroglucinol a red colour. No free sulphate was detected.

From this substrate, enzymes of a Gram-negative bacillus in pure culture have been found capable of quantitative release of sulphate. The organism used is No. 3247, National Collection of Type Cultures, *Ps. non-liquefaciens*. Neuberg[5] has described three sulphatases in Gram-negative bacilli, of which two are of interest in connexion with the present work: chondrosulphatase, which releases sulphate quantitatively from chondroitin sulphuric acid, while a similar type of enzyme releases sulphate from the mucoitin sulphuric acid of mucin.

An explanation of caries developing in enamel may be as follows. Enamel protein resembles a mucoprotein in its properties. Gram-negative bacilli, commonly found in caries, can release sulphatase. Enamel is made up of hexagonal prisms each surrounded by a sheath of enamel protein. Enzymatic hydrolysis of these sheaths in caries, with release of sulphuric acid, would result in attack on each prism from the periphery inwards; the relatively insoluble calcium phosphate which forms the inorganic part of the enamel would be slowly changed to the relatively soluble calcium sulphate. It is of interest to notice that Frisbie *et al.*[6] show enamel caries proceeding in just such a manner, each prism decreasing in size from the outer edge inwards.

To summarize: (1) quantitative estimations of nitrogen and of sulphur, together with evidence from the developmental aspect and from histochemical tests, suggest that enamel protein is a mucoprotein; (2) the presence of a chondrosulphatase in certain Gram-negative bacilli is confirmed; (3) the mode of progress of caries in enamel, studied histologically, can be accounted for by the present hypothesis.

The Medical School of the Middlesex Hospital gave facilities for this work through the kindness of Prof. Samson Wright. Dr. Alan Morgan, Westminster Hospital Medical School, kindly gave access to histological material. The Medical Research Council provided financial assistance. Grateful thanks is made for these facilities.

Microflora of the Rumen

QUIN[1], in his study of the rumen micro-organisms occurring in sheep fed exclusively on lucerne hay, noted the appearance of large numbers of ovoid, clear cellular organisms with an average size of 8 μ × 4 μ. He showed that rumen fluid rich in these organisms rapidly fermented glucose with the evolution of gas, and that under these conditions the organism stained mahogany brown on the addition of aqueous iodine solution. He did not state whether these organisms were motile, nor did he record any attempts at isolation by cultural methods. On the basis of their apparent reproduction by binary fission and their fermentative powers, Quin considered that these organisms were a type of false yeast, and accordingly named them '*Schizo-saccharomyces ovis*'.

Baker[2] and Elsden[3] have confirmed these observations, apparently acquiescing in the use of the term '*Schizo-saccharomyces ovis*'.

We have examined repeatedly the rumen contents of sheep, with permanent fistulæ, fed on a diet of meadow hay and mangolds, and have found that ovoid yeast-like forms are the overwhelmingly predominant organisms. In sheep fed on meadow hay only, these ovoid organisms are absent or in small numbers; but within three days of the addition of mangolds to the diet, they appear in great numbers.

In wet preparations under a coverslip, examined under the 1/6th eyepiece of the microscope soon after sampling, the majority of the ovoid forms are seen to be actively motile; but so far, no flagella have been detected either in stained or unstained preparations. Many of the forms appear to have an outer layer resembling an envelope or capsule, around the periphery of which there are a number of small granules, brightly refractile in unstained preparations and staining intensely with Giemsa.

As well as the ovoid forms, there are numerous crescent-shaped forms of approximately the same dimensions; in some individuals one long flagellum, in others two flagella, attached to the centre of the concave side can be detected.

If a relatively pure suspension of these ovoid and crescentic organisms is obtained by fractional centrifugation, mixed with 10 per cent glucose solution and incubated at 37° C., there is a rapid evolution of gas and reduction in *p*H. On microscopic examination, the organisms are found to be non-motile; on mixing with iodine solution, they stain deep mahogany brown, indicating the formation of glycogen.

Thus it would appear that we are dealing with the organisms termed '*Schizo-saccharomyces ovis*' by Quin, and, in disputing the use of this term, we wish to direct attention to a publication by Woodcock and Lapage[4], in which they describe observations on an oval and crescentic organism found in great numbers in the rumen contents of sheep and goats. They were able to demonstrate a single flagellum arising from the centre of the body in the crescent-shaped forms, but were unable to demonstrate a flagellum in the oval motile forms. After examination of authenticated strains of *Schizo-saccharomyces*, they stated that, in their opinion, these organisms were not related to that yeast. On the grounds that similar organisms had been described by Certes[5], they preferred to name them *Selenomastix ruminantium* (Certes). This protist is now referred to as *Selenomonas ruminantium* in the standard text-books on protozoology[6,7].

We have made numerous attempts to culture the ovoid and crescentic organisms using various media, incubated at temperatures ranging from 20° C. to 45° C., aerobically, anaerobically and in vessels containing additional carbon dioxide, but so far without success. At least four different types of yeasts have been recovered by one of us (C. A. McG.), but none of these appears to belong to the genus *Schizo-saccharomyces*. In view of the statement of Klein and Müller[8] that nectar yeasts play an important part in ruminant digestion, a detailed examination of the yeasts isolated is being pursued. It must be admitted, however, that yeasts appear to be present only in small numbers.

In conclusion, we suggest that the yeast-like organisms observed in the rumen contents are not *Schizo-saccharomycetes* but are the protists described by Certes[5] and by Woodcock and Lapage[4] and now named *Selenomonas ruminantium* (Certes).

Chromosome Number of *Cardamine pratensis*

I notice with interest Dr. Howard's records of chromosome counts of $2n = 56$ for several plants of *Cardamine pratensis* growing in damp places[1]. I have been working on British plants of this species for the last two years, with the help and guidance of Dr. K. B. Blackburn, and I have collected a very considerable amount of information on its chromosome number. The normal plant which grows in damp meadows has constantly the chromosome number $2n = 56$, judged from the evidence of seventy plants collected from eighteen vice-counties. Plants with semi-double flowers, first described by Dr. Wilfred Robinson[2] in 1925, have been found in fifteen localities in wet places, chiefly in the north of England. They have the same chromosome number $2n = 56$. Plants with $2n = 30$ chromosomes seem to be characteristically from the south of England. Those examined include five normal plants and seven completely sterile double-flowered plants. No other chromosome numbers than these have so far been encountered.

The ecological difference found by Lövkvist holds good in most of the cases recorded; for example, Prof. R. D'O. Good, who kindly provided material from Dorset, noted particularly that the large plant, now found to have the low chromosome number, occurred in quantity on the damp roadside banks characteristic of Marshwood Vale, whereas the smaller darker-leaved one ($2n = 56$) grew in wet meadows.

As I am now trying to map the distribution of the different forms of *Cardamine pratensis*, I should be very grateful for living plants particularly from Scotland, the south and east coasts of England and Ireland.

Distribution Patterns in European Basidiomycetes with Reference to Some British Species

Nineteenth-century mycologists, impressed by the wide distribution of agarics and polypores, were inclined to regard them as truly cosmopolitan. Subsequent experience has modified this view by indicating that, at least as regards Basidiomycetes, the flora of tropical regions does not usually consist of the same species as that of the north temperate zone. It is also often doubtful whether a specific epithet has been applied to the same species in North America as in Europe. Even within a rather small area such as Europe, gradually accumulating distributional data have shown that not all the higher fungi occur in all parts of the Continent. Thus, in the comparatively rich British Basidiomycete flora, it is possible to distinguish components characteristic of different Continental regions. For the present it may be sufficient to recognize a northern European, southern European and Oceanic type of distribution; but when the European fungus flora has been adequately studied from this point of view, it will probably be possible not only to define these with greater precision but also to recognize other, smaller, mycological provinces.

A typical example of the northern European group is *Exidia repanda* Fr. The European distribution of this species, as quoted by Neuhoff[1], is shown in Fig. 1. Here the individual crosses in the Scandinavian peninsula do not represent separate collections but cover the reported range of the species. This very distinct and easily recognizable fungus was collected for the first time in Britain on birch trees at Shieldaig, Wester Ross, in June 1947. It seems unlikely that such a conspicuous species can have escaped observation in England; if it does occur there at all it must be rare or sporadic. Fungi of the northern European

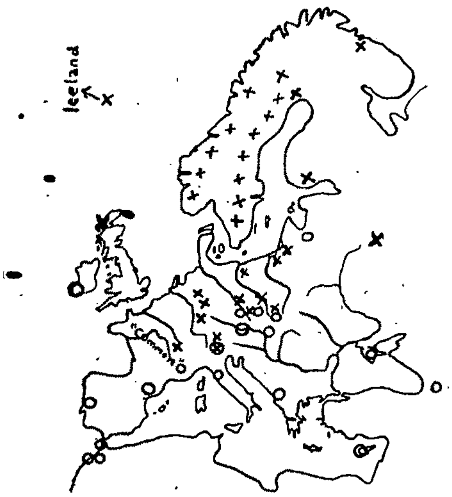

Fig. 1. ×, *Exidia repanda*; o, *Polyporus torulosus*

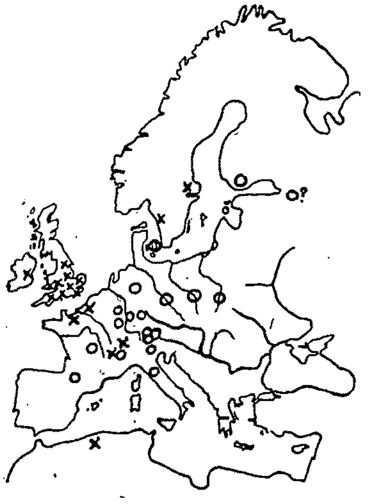

Fig. 2. ×, *Pleurotus palmatus*; o, *Ditangium cerasi*

group are likely to have a circumpolar range, and Neuhoff suggests that *E. repanda* is identical with species described from North-East Asia and from North America.

Fig. 2 shows the European distribution of a typical Oceanic species, *Pleurotus palmatus* (Bull. ex Fr.) Quél., according to Pilat[2], who rejects as erroneous all German and central European records of this fungus. If it occurs at all in central Europe it must do so very rarely, for when Pilat published his monograph of *Pleurotus* he had never seen a fresh specimen of it. Within the British Isles the species appears to be prevalent only in the south of England. There are some twenty-three published collections of it from south of the Humber, only four from England north of the Humber and none from Scotland. *P. palmatus* was not known to Lange in Denmark and the Swedish occurrences appear to constitute a somewhat anomalous extension of its range. Dr. Jørstad kindly informs me that it has not yet been found in Norway.

A species with a conspicuously southern European distribution is *Polyporus torulosus* Pers., identified by Miss Wakefield for the first time from Britain in a collection made by me on *Arbutus unedo*, Killarney, in August 1946. Its known range in Europe is plotted in Fig. 1 from the data of Pilat[3]. Except for a single record from the neighbourhood of Riga, perhaps in need of confirmation, the species appears to be unknown in Europe north of about lat. 52° N. Details are unfortunately lacking regarding its range in France; Bourdot and Galzin[4] merely state that it is common in that country. Its extra-European distribution is said to include China, Japan and the southern United States of America.

There is also a considerable group of species with a Continental type of distribution which do not reach the British Isles. Typical of these is *Ditangium cerasi* (Tul.) Cost. and Duf., the range of which is plotted in Fig. 2 for comparison with that of Oceanic species.

It is as yet impossible to estimate the relative proportions of these and other geographical components in the British fungus flora. Not only is there too little information available regarding the distribution of the larger fungi throughout Europe but also, to a greater extent than in any other group of plants, one can usually draw no reliable inferences from such local lists of species as have been published. Too often, especially in Agaricaceæ, species have been interpreted by different authors in widely differing senses. Thus, unless a full description is given of the individual collection cited, or it is definitely stated to conform to the conception of the species by some well-known authority, the published names have little value. This difficulty in standardizing the interpretation of species makes it especially desirable that British and Continental mycologists should have ample opportunity of meeting and studying disputed species together in the field. The attendance of many prominent European mycologists at the British Mycological Society's semicentenary celebrations in 1946 was a welcome step, made possible by the British Council; but much more frequent contact is required, and especially the provision of facilities for British mycologists to study the European fungus flora in the field.

Puffinosis, a Virus Epizootic of the Manx Shearwater (*Puffinus p. puffinus*)

In the years 1946 and 1947, epizootics have been observed among the manx shearwaters on the island of Skomer off the Pembrokeshire coast[1]. The birds affected have been juveniles nearly ready to leave the island. The disease is characterized by the occurrence of large blisters on the web, either plantar or dorsal surfaces. In 1946 severe conjunctivitis was also a notable feature, but was rare in 1947. Some birds show spasm of the legs shortly before death. It is estimated that at least 90 per cent of the birds with clinical signs die of the disease.

At post-mortem some birds show no definite lesions other than those in the web. Others have round patches of consolidation in the lungs. Histologically, the web around the blisters shows great inflammatory change, and acidophil cytoplasmic inclusions may be seen in the cells of the epidermis. Cultures of the blister fluid yield either a mixed culture or a pure culture of *Staphylococcus aureus*.

Bacteriologically sterile blood from a shearwater moribund from the disease was inoculated on to the chorio-allantoic membrane of embryonated hen's eggs of varying ages, and lesions suggesting a virus infection were found. Sections of these membranes showed ectodermal proliferation, some mesodermal reaction and homogeneous acidophil inclusions in the cytoplasm of the ectodermal cells. Passage in the embryonated hen's egg did not readily yield easily recognizable macroscopic lesions, although microscopic lesions containing typical inclusions were always present. From the thirteenth passage onwards, minute pocks 0·05–0·2 mm. in diameter have been regularly observed 72 hours after inoculation; but because of their minute size, titration of the virus by pock counting methods is impracticable.

When ducklings one to two weeks old were inoculated with either original shearwater or egg-passage material by light scarification of the dorsum of the web of one foot, a disease closely resembling that in the shearwater developed after about three days. Blisters occurred on the inoculated webs, and many of the birds which died also showed lung lesions similar to those in the shearwater. Such lesions have not been found in controls.

Attempts have been made to estimate the approximate size of the virus particle by filtration through 'Gradocol' membranes. When tested either in eggs or in ducklings, it has been repeatedly shown that small amounts of virus pass through membranes having an average pore diameter of 48 m . Membranes of smaller pore diameter have not been available.

Material from the twentieth egg passage was found to give typical lesions in ducklings when diluted 10^{-7} but not at 10^{-9}. A neutralization experiment was carried out in ducklings using diluted material from this egg passage with serum from a shearwater which died in the acute stage of the disease, and a pool of serum from two which had survived exposure to the disease. With the acute serum, one duckling out of five showed infection when inoculated with material diluted to 10^{-7} and four out of five when diluted 10^{-6}. With the survivor serum no infections occurred at either dilution. The acute serum did not fix complement in 1 hour at 37° C. in the presence of antigens made either from the organs of infected ducklings or from infected chorio-allantoic membranes, while the survivor serum fixed two minimal hæmolytic doses of complement to a dilution of 1 : 10 in the presence of both antigens.

Virus was inoculated by scarification into the plucked breasts of four adult pigeons. Large blisters developed on the sixth day on two of these birds. The virus was recovered from the blister fluid. Lesions have not been produced by primary inoculation of the virus either into the comb of a cockerel or into the plucked breasts of four-week-old chicks.

Attempts have been made to pass the virus to the rodents in common use in the laboratory. The original material from shearwaters was inoculated into mice by various routes without any definite lesions being obtained. Inoculation of twentieth egg passage material into young guinea pigs, rabbits and rats or into adult mice by scarification into the pads, or in young guinea pigs and rabbits by inoculation intradermally into the dorsum of the tongue, have not yielded any definite evidence of infection.

There is some evidence that juvenile herring gulls (*Larus argentatus*) have been infected in Nature, and it is highly probable that investigations might show a wider distribution of the disease. We suggest that the name 'puffinosis' is suitable for this epizootic disease of *Puffinus puffinus puffinus*.

Theory of Superconductivity

The present note is a continuation of another one submitted recently to *Nature* [see *Nature*, June 19, p. 968]. The calculations reported here are mainly due to the junior author.

The explanation given for superconductivity consisted in showing that in certain metals, characterized by a certain ratio of the lattice constant in the reciprocal space to the radius of the Fermi surface, the lowest energy state corresponds to a distribution with spontaneous currents. We obtained an expression of the correct order of magnitude for the transition temperature. Here we shall show that these spontaneous currents arrange themselves in a magnetic field in such a way that, for weak fields, London's equations between current and field hold, while for strong fields deviations are to be expected.

An investigation of the energy-levels of the electronic motion shows that they are little influenced by an external magnetic field. This effect can be rightly ignored, and the magnetic energy simply added to that of the electrons. Then the total free energy is (compare the previous note)

$$F = \int \left\{ U_0 + \frac{1}{2}\,\omega^2 \frac{h^2 n^2}{4\pi m} \left(\frac{\pi}{3n_0}\right)^{1/3} - \frac{\omega}{\omega_0} \frac{2\pi^3 m}{3h^2} \left(\frac{3n_0}{\pi}\right)^{1/3} (kT)^2 + \frac{1}{8\pi} H^2 \right\} d\tau. \qquad (1)$$

Now the spontaneous current is proportional to the number of the occupied corners of the Brillouin zone $\omega_0 - \omega$, so that the magnitude of the spontaneous current density is

$$j = \frac{nev_s}{c}\,(\omega_0 - \omega), \qquad (2)$$

where $v_s = \frac{hn^{1/3}}{m^*} \sim 3\cdot3 \times 10^7$ cm. sec.$^{-1}$ is the velocity of the superconducting electrons. Neglecting ordinary (Ohm) currents which are short-circuited by the superconductive regions, one has the relation

$$4\pi\mathbf{j} = \text{curl } \mathbf{H}. \qquad (3)$$

Introducing (2) and (3) one obtains,

$$F = F_0 + \frac{1}{8\pi} \int \left\{ \mathbf{H}^2 + \beta^2 (\text{curl } \mathbf{H})^2 - \gamma\,|\,\text{curl } \mathbf{H}\,| \right\} d\tau, \qquad (4)$$

with the abbreviations

$$\left.\begin{aligned} \beta^2 &= \frac{h^2 c^2}{(4\pi)^2 m e^2 v_s^2} \left(\frac{\pi}{3n_0}\right)^{1/3}, \\ \gamma &= \frac{hcn\omega_0}{2\pi m e v_s} \left(\frac{\pi}{3n_0}\right)^{1/3} \left(1 - \frac{T^2}{T_0^2}\right). \end{aligned}\right\} \qquad (5)$$

The field distribution is obtained by minimizing the expression (4) with respect to **H**, taking into account the continuity of **H** on the boundary. We split $\mathbf{j} = \frac{1}{4\pi}$ curl **H** into two parts:

$$\mathbf{j} = \mathbf{j}_0 + \mathbf{j}', \text{ where } (\mathbf{j}_0)_{\text{av}} = 0.$$

If $|\,\mathbf{j}_0\,| > |\,\mathbf{j}'\,|$, which happens for small fields, one gets London's equation for the stationary case:

$$\Delta\mathbf{H} = \lambda\mathbf{H}, \qquad (6)$$

with $\lambda = \frac{3}{\beta^2}$, $\frac{1}{\sqrt{\lambda}} = \frac{\beta}{\sqrt{3}} \sim 3 \times 10^{-6}$ cm.

On the other hand, if the external field is large, then London's equation breaks down and has to be replaced by the following one:

$$\Delta \mathbf{A}\left(1 + \frac{\gamma\,|\,\mathbf{j}_0^2\,|}{6\beta^2\,|\,\Delta \mathbf{A}\,|^3} - \frac{\gamma}{2\beta^2\,|\,\Delta \mathbf{A}\,|}\right) = \frac{1}{\beta^2}\,\mathbf{A}, \qquad (7)$$

where **A** is the vector potential.

Even for large fields the region where equation (7) holds is only a thin boundary layer, the thickness of which (the penetration depth δ) is obtained by postulating that the function **H** is continuous across the surface between the boundary layer and the interior where the London equation (6) holds. One obtains for very strong external fields H_0 (for which no experimental results are available)

$$\delta = 0{\cdot}47\,\beta\,\sqrt{\frac{H_0}{H_f\,(1 - T^2/T_0^2)}}, \qquad (8)$$

where H_f is a constant.

The threshold magnetic field is obtained by equating the free energy of the normal and the superconducting states. The first is $F_0 + \frac{1}{8\pi}\int \mathbf{H}_0^2 d\tau$, where $\mathbf{H}_0$ is the external magnetic field; and the second is the expression (4), where **H** is the superconductive field. The calculation leads to the formula

$$H_c = H_m\,(1 - T^2/T_0^2), \qquad (9)$$

with

$$H_m = T_0^2\,\frac{8\pi^4 m k^2}{3h^2}\left(\frac{3n_0}{\pi}\right)^{1/3}. \qquad (10)$$

This agrees with the experimental results, not only with respect to the dependence on the temperature T, but also to the order of magnitude.

Mechanism of the Emission Spectrum of Active Nitrogen

IN a recent paper Mitra[1] has attempted to explain the remarkable features of the nitrogen afterglow, which have also been studied again by Lord Rayleigh[2] on the assumption of an emission that would follow the recombination between the ions N_2^+ with electrons. It seems difficult to explain the previous observations and those described here by this simple hypothesis.

We have shown in previous work[3] the existence of complex afterglow arising from the overlapping of several mechanisms. Besides the long duration of the yellow afterglow (α-bands) we observe a short one which consists of the first positive system without definite selectivity, the second positive and the first negative systems. The distribution of intensity of this afterglow changes with the pressure and the action of the walls.

Working with the phosphoroscope of P. Lejay[4] we have also investigated qualitatively the effect of temperature on this afterglow. A comparison was made between the emissions at the surrounding temperature and when liquid air was poured in the Dewar vessel in which the discharge tube was immersed. Under these conditions we observed the following modifications in the composition of the afterglow.

As in the case of the yellow emission, a rise of the intensity of the whole of the spectrum at low temperature is observed, but it is not of the same weight for all systems.

First positive system. At laboratory temperature, there is a strong emission without a striking selection; its relative intensity rises when the pressure decreases and the temperature increases. At low temperature, the distribution of intensity in the sequences changes because of the increase of the bands at $v' = 6$ and 10 (α-bands).

Second positive and first negative systems. At a pressure of 10^{-2} mm. to 10^{-1} mm. mercury, their intensity increases about three times at 10^{-4} sec. after breaking up the discharge. The bands with $C^3\Pi$, $v' = 3{\cdot}4$ increase in relative intensity in afterglow.

Goldstein bands. At low temperature, this system increases in relative intensity. When the discharge is cut off, it suffers less variation than the neighbouring bands of the second positive system (Fig. 1). The emission of this system follows a recombination between two atoms of nitrogen (^2D) in a similar way to the bands with $C(v' = 3{\cdot}4)$ of the second positive system. The similar behaviour of these bands belonging to different systems confirms our interpretation.

Green system. The three strongest bands λλ 5079 (0·0), 5308 (0·1), and 5570 (0·2) continue in the afterglow with greater strength at low temperature (Fig. 2).

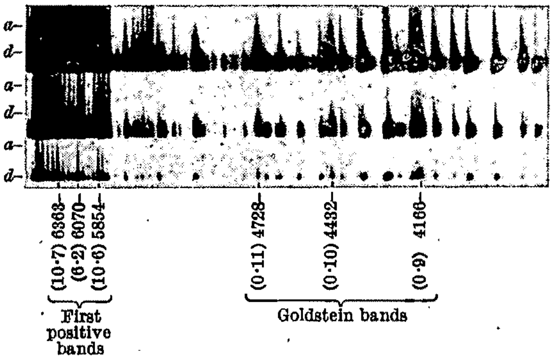

Fig. 1. CHANGES OF THE NITROGEN SPECTRUM WHEN THE DISCHARGE IS CUT OFF (LOW TEMPERATURE).
d, discharge; *a*, afterglow

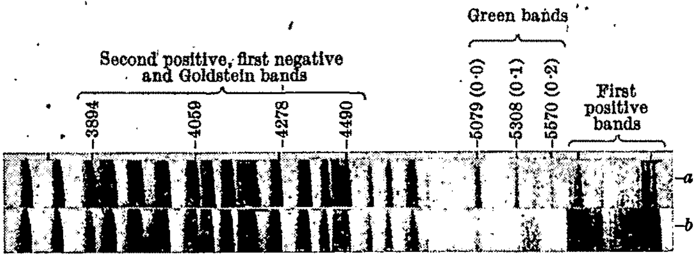

Fig. 2. COMPARISON BETWEEN THE AFTERGLOW SPECTRA AT LOW TEMPERATURE (*b*) AND LABORATORY TEMPERATURES (*a*)
The decrease of the relative intensity of the first positive and the rise of the green bands should be noted in spectrum (*a*)

Our results show that the hypothesis of Mitra is unable to explain all the features of active nitrogen. The strong emission of the first negative system must result from a recombination of the doubly ionized ions N_2^{++} and electrons. To account for the increase of the Goldstein and selected bands of the second positive system, we must assume an atomic recombination. Likewise the selective emission of the first positive system is made clear by the Carion and Kaplan mechanism in which one molecule of nitrogen ($A^3\Sigma$, $v = 0$) is excited by an atom of nitrogen (^2D) or (^2P). It is possible also that the emission of the bands at $B(v' = 6)$ results from the interaction with the $^1\Pi$-level. For example, it would not seem possible to admit that the emissions of the first and second positive systems follow the same mechanism of capture of electrons:

$$(N_2^+ + e \rightarrow C^3\Pi \rightarrow B^3\Pi + h\nu \text{ (second positive)};$$
$$B^3\Pi \rightarrow A^3\Sigma + h\nu \text{ (first positive)};$$

since it would not account for the great variations in their relative intensity with the experimental conditions.

The remarkable features of active nitrogen seem rather to result from the fact that this diatomic molecule is like an inert gas that permits many reactions between atoms, ions and electrons.

Reported Radioactivity of Osmium

FOR some time it has been known that two isobars which differ by unity in atomic number cannot both be stable, except for a possible influence of the neutrino if its mass has a positive value at rest. A search for radioactivity among the existing pairs of isobars led to the announcement[1] of K-electron capture in osmium (Os^{187}) with a half-life of about 3×10^8 years. However, a recent paper on beta-stability[2] contains the following remark: "The reported radioactivity of Os^{187} has recently been questioned, with indications that Re^{187} instead is radioactive"[3]. It seems worth pointing out that some time ago another argument had thrown strong doubts on the view that osmium is radioactive.

This conclusion rests on data, contained in a paper by Noddack and Noddack[4], which gives the results of rhenium determinations in a number of minerals. These authors find the rhenium content of osmiridium from New South Wales to be about 10^{-5} per cent and of a sample from the Urals about 10^{-4} per cent. From what is known about the rocks from which the platinum ores originate, we may take 2×10^8 years as a fair estimate of the age of most of the osmiridium samples investigated by Noddack. Osmiridium usually contains between 30 and 50 per cent osmium, and 1·64 per cent of the latter is Os^{187}. Therefore, if the rate of radioactive decay quoted above were correct, osmiridium should contain about $\frac{1}{4}$ per cent rhenium. Although the figures for the rhenium content and for the age of osmiridium are admittedly inaccurate, the discrepancy of at least something like 10^4 is sufficiently large to prove that, if K-electron capture occurs in osmium, the half-life must be several orders of magnitude longer than that given by Lougher and Rowlands.

The Metallic State

IN the development of the resonating-valence-bond theory of metals, it has become evident that the characteristic structural feature of metals is the possession by each atom or each of many atoms in the metallic phase of an extra orbital (the 'metallic orbital'), in addition to the orbitals normally occupied by electrons. This metallic orbital permits the unsynchronized resonance of electron-pair bonds from one interatomic position to another by the jump of one electron from an atom to an adjacent atom, leading to great stabilization of the metal by resonance energy, and to the characteristic metallic properties.

For example, in lithium each atom has one valence electron, permitting the formation of an electron-pair bond for each pair of atoms. These bonds resonate among alternative positions, mainly the eight positions between each atom and its eight nearest ligands. If each atom were required to remain neutral, by retaining its valence electron, the stabilization through the permitted synchronized bond resonance,

$$\left\{\begin{array}{lll} \text{Li—Li} & \text{Li} & \text{Li} \\ & | & | \\ \text{Li—Li} & \text{Li} & \text{Li} \end{array}\right\},$$

analogous to that in the benzene molecule, would be relatively small. Much greater stabilization results from unsynchronized resonance such as

$$\left\{\begin{array}{lll} \text{Li—Li} & \text{Li}^{-}\text{—Li} & \\ & | & \\ \text{Li—Li} & \text{Li} & \text{Li}^{+} \end{array}\right\},$$

involving the use of an additional orbital on the atom receiving an extra bond. The electronic conductivity and other characteristic properties of metals may be described in terms of the transfer of the positive and negative charges from atom to atom accompanying the resonance of the valence bonds.

The resonance energy resulting from use of the metallic orbital in metals outweighs the energy of repulsion of adjacent non-bonded atoms and permits the co-ordination number of atoms to be greater than the number of valence electrons or bond orbitals. Thus tin, with 14 outer electrons and 9 stable orbitals (five *4d*, one *5s*, and three *5p*, or hybrids of them), may place electron pairs in five orbitals and single electrons in the other four; this quadrivalent tin, with no extra orbital, forms the essentially non-metallic phase grey tin, with the diamond structure (co-ordination number 4, non-resonating single bonds). However, a metallic orbital can be made available by placing six unshared electron pairs in six orbitals, and single electrons in two orbitals. This bivalent tin is present in the metallic phase, ordinary white tin, in which each atom has co-ordination number 6.

It is not necessary that every atom in a metallic system have a metallic orbital. The four bonds of each quadrivalent tin atom in the compound AuSn[1] are able to resonate among the six positions to the six adjacent gold atoms by pivoting around the tin atom, making use of the extra orbitals of the gold atoms. About one quarter of the atoms in white tin are quadrivalent, the average valence thus being about $2\frac{1}{2}$, and the average number of metallic orbitals per atom about $\frac{3}{4}$. These considerations thus explain the previously puzzling non-integral number 0·78 of extra orbitals per atom and the non-integral valencies, such as 2·44 for tin, which were found ten years ago by the analysis of magnetic data[2].

The problem of the choice between alternative structures for a metal or intermetallic compound that satisfy the metallic valencies of the atoms equally well can be discussed by a treatment resembling the customary Brillouin-zone theory, but involving the resonance of electron-pair bonds throughout the crystal, rather than of single electrons. We may, as an approximation, formulate the wave function for a crystal as an electron-antisymmetrized combination of product functions constructed of two-electron functions, each of which represents an electron-pair bond resonating among the inter-atomic positions in the crystal. These two-electron functions may be set up as a combination of bond functions multiplied by suitable Bloch factors; the resonance energy then leads to a splitting of energy levels qualitatively similar to that given by the usual one-electron molecular orbital theory, and with the same electron numbers for the Brillouin polyhedra. The agreement between the newly proposed metallic valencies of the transition metals and the electron numbers filling important Brillouin polyhedra for some filled-zone substances (the γ-alloys, α-manganese, β-manganese) has been pointed out in a recent paper[3].

Another way of discussing the choice between alternative structures is based upon the special stability associated with the resonance of valence bonds among interatomic positions when the ratio of bonds to positions is that of small integers. This effect most strongly stabilizes bonds with bond number $\frac{1}{2}$ (half-bonds), corresponding to resonance of one bond between two positions, followed by bonds with bond numbers $\frac{1}{3}$, $\frac{2}{3}$, $\frac{1}{4}$, $\frac{3}{4}$, etc. It is thus possible to understand the stability of the unusual metal structures shown by zinc, cadmium, mercury, white tin, gallium, β-tungsten, β-uranium and a few other metals, as well as that of the structures of many intermetallic compounds. For example, if zinc, with metallic valency 4·5, had a normal close-packed structure, each of the twelve bonds formed by a zinc atom would be a $\frac{3}{8}$-bond. By increasing the axial ratio of its crystal from the value 1·633 (for hexagonal close packing) to 1·861, each zinc atom is able to form six half-bonds (of length 2·660 A.) and six quarter-bonds (2·907 A.), and the crystal gains the extra stability accompanying these simpler bond numbers. Similarly, the selection of the body-centred structure by the fifth-group elements can be understood: this structure, in which each atom uses its valency 5 to form half-bonds with its nearest eight ligands and $\frac{1}{6}$-bonds with the six more distant ones, is in consequence of the simple bond numbers more stable than a close-packed structure, involving twelve $\frac{5}{12}$-bonds.

This resonating-valence-bond theory of metals will be discussed in detail elsewhere.

Adsorption on to Ionogenic Surfaces

Michaelis and Ehrenreich[1] were the first to suggest that the adsorption of large ions such as the organic dyes, on ionogenic surfaces, takes place by two distinct mechanisms operating simultaneously: one of an electrochemical nature, and in addition to this a 'normal' physical adsorption. Later, Freundlich and Poser[2] stated explicitly that the adsorption of large positive ions on clays could be explained qualitatively by the combined effects of an irreversible ion-exchange adsorption and a reversible physical adsorption, and this idea was further elaborated by Michaelis and Rona[3]. It is interesting for the historian of science that this simple idea was afterwards forgotten, but was 'rediscovered' on several occasions prior to our work. The idea of simultaneous adsorption by two different mechanisms is not mentioned by Swan and Urquhart[4] in their comprehensive review on adsorption, or in text-books. Even Freundlich himself in his "Kapillarchemie" (1930) seems to have lost sight of the implications and usefulness of the idea, but it was formulated in different ways by Stadnikoff[5], Fogle and Olin[6], Hendricks[7] and Grim *et al.*[8].

We have arrived independently at the conclusion that the adsorption of basic dyes on clays is governed by two essentially different mechanisms. It is known that when basic dyes are adsorbed on clays a certain fraction of the adsorbed amount is held irreversibly and displaces an approximately equivalent quantity of cations from the clay[3a,9]. If this exchange adsorption is absolutely irreversible, the amount of dye held in this way will be directly proportional to the quantity of clay present and independent of the dye concentration in the solution. If we bring increasing quantities of dye into contact with a given mass of clay, at first every molecule of dye added to the system will be adsorbed and held irreversibly, and this will go on until the base-exchange capacity of the clay is saturated. As soon as there is an excess of dye present, it will be physically adsorbed on to the exchange-saturated clay. The quantity of dye thus held will be a function of the concentration of dye remaining in solution after the portion held by ionic exchange has been taken out. From these considerations it follows that, in general, the number of milli-equivalents x of dye taken out of v ml. of a solution of initial concentration c_0 m.equiv./ml. by m gm. of clay will be a function of m, c_0 and v. This treatment is a first approximation: it neglects the possibility that, on account of the accessibility of exchange sites to the large dye molecules, the exchange capacity for dyes may be less than the general base-exchange capacity; it also neglects time effects and possible transitions between the two states of adsorption.

This theory of adsorption can be formulated quantitatively thus. Let x_1 and x_2 be the 'exchange' and 'physical' contributions to the total adsorption.

Then $x = x_1 + x_2$,

but $x_1 = k_1 m$, where k_1 = constant,

so that the quantity of dye remaining in solution after the exchange adsorption is given by $(vc_0 - x_1)$. This will set up a reversible equilibrium which may be described, for example, by a Freundlich isotherm with constants k_2 and n. If c is the final concentration of dye in the solution,

$$x_2 = m.k_2.c^n.$$

Therefore $x = m(k_1 + k_2c^n)$,

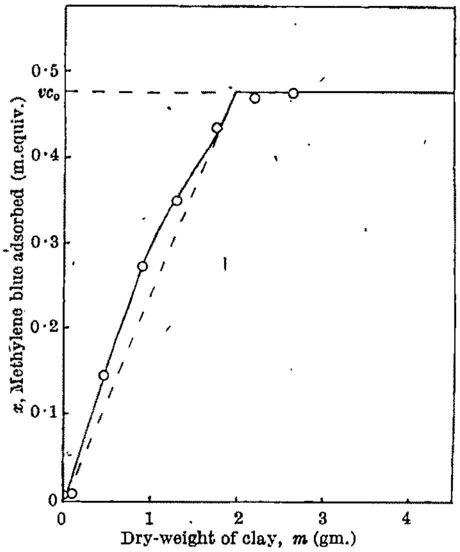
or since $c = c_0 - x/v$

$$x/m = k_1 + k_2(c_0 - x/v)^n.$$

This equation was found empirically by Gurwitsch[10] but was misinterpreted and its significance overlooked. It defines a surface in the $(x - m - c_0)$ diagram which will be characteristic for each system. At constant c_0 and v we have:

$$\frac{dx}{dm} = \frac{k_1 + k_2c^n}{1 + \frac{mn}{v}k_2c^{n-1}}.$$

As $m \rightarrow 0$ and thus $c \rightarrow c_0$, $dx/dm \rightarrow k_1 + k_2c_0{}^n$. As $c \rightarrow 0$ with increasing m, $dx/dm \rightarrow k_1$. The shape of this (x,m) curve is represented by the full line in the diagram. Experiments by one of us (P. H. P.) with various clays, in which x was measured for methylene blue as a function of m at constant c_0 and v, gave results such as those for floridin shown in the graph. The agreement with the shape of the theoretical curve is reasonable, except where $x \rightarrow vc_0$. This discrepancy is probably due to the approximations used in the theory. It is smaller for Wyoming bentonite, for example, for which k_1 is greater than k_2. For all values of m greater than a certain critical value m_0, x = const. = vc_0; m_0 is the weight of clay which is exactly 'exchange-saturated' by vc_0 m.equiv. of dye, that is, the exchange adsorptive capacity of the clay is given by vc_0/m_0. Although for some clays m_0 is rather indefinite, the value of $vc_0/m_0 = k_1$ agrees well with the base exchange capacity of the clays, as is to be expected. k_1 can be found from measurements such as those represented in the graph. Knowing k_1, then k_2 and n can be found from the plot of log $(x/m - k_1)$ against log c. Alternatively, k_1 is given by the intercept of the $(x/m, c)$ plot on the axis of x. (We are indebted to Dr. M. Szwarc for pointing this out.)



ADSORPTION OF METHYLENE BLUE ON FLORIDIN CLAY. v = 50 ml. c_0 = 0·357 PER CENT

Since the derivation of the theory outlined above is very general, it should be applicable wherever adsorption takes place by a combination of reversible and irreversible mechanisms; for example, dyeing, staining, adsorption on humus, peat, polymeric acids, ion-exchange resins, etc.

The subject will be treated more fully in a forthcoming publication.

A Simple Moving-Boundary Apparatus

Baxter and Gold[1] in their letter under the above title appear to be unaware of a paper by Drew and Hartley[2] describing the similar use of a single three-way tap arrangement for bringing together the leading and indicator solutions in the moving-boundary method of transport number measurement. As the apparatus described by Drew and Hartley was employed in the development of a new method for the measurement of transport numbers and might be overlooked, Baxter and Gold may be justified in directing attention to this simple experimental arrangement. I do not, however, share their views regarding the superiority of the tap arrangement over certain other conventional apparatus. I have had some experience of various types of moving-boundary apparatus, including one similar to that described by Baxter and Gold. I found that the air-lock device described by Hartley and Donaldson[3] not only possessed the qualities claimed by Baxter and Gold for their tap arrangement but also was superior in other respects. Thus the air-lock device allows of greater ease of manipulation when the apparatus is supported in a thermostat, and its avoidance of a lubricant is a desirable feature in studies with non-aqueous media. Moreover, its inexpensiveness relative to a good-grade tap, its simplicity together with its ease of construction, render the device very appropriate for use in undergraduate practical courses.

X-RADIATION FROM A 20-MeV. BETATRON

By W. BOSLEY, DR. J. D. CRAGGS
AND
W. F. NASH
High Voltage Laboratory, Metropolitan-Vickers
Electrical Co., Ltd., Manchester
AND
R. M. PAYNE
A.E.I. Research Laboratory, Aldermaston, Berks

IT is of interest and importance to know the energy distribution of the radiation emitted from betatrons and synchrotrons, since such knowledge is necessary in cases where cross-sections of nuclear reactions are to be determined[1], and in estimating the clinical effect of such radiation.

For some months we have been investigating the spectrum of the radiation from the 20-MeV. betatron (Kerst type) built in this Laboratory, using two methods, namely, the study of (*a*) electron-positron pairs produced in a thin lead sheet in a Wilson chamber, and (*b*) the protons liberated in the photodisintegration of deuterons using either a scattering chamber with a heavy wax target or deuterium-loaded plates (Ilford *C*2 Emulsion). Lasich and Riddiford[2] have investigated independently the spectrum of the X-rays from a 2·8-MeV. betatron using Compton recoil electrons.

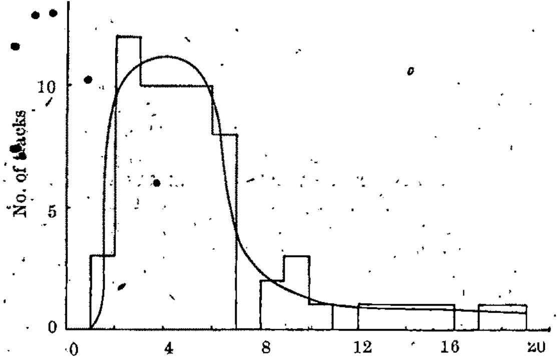

Fig. 1 (*a*)

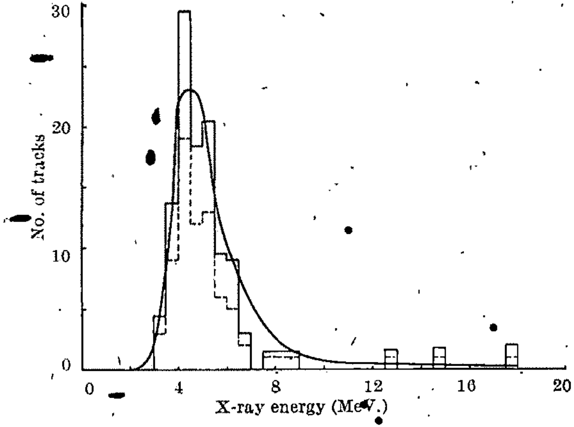

Fig. 1 (*b*)

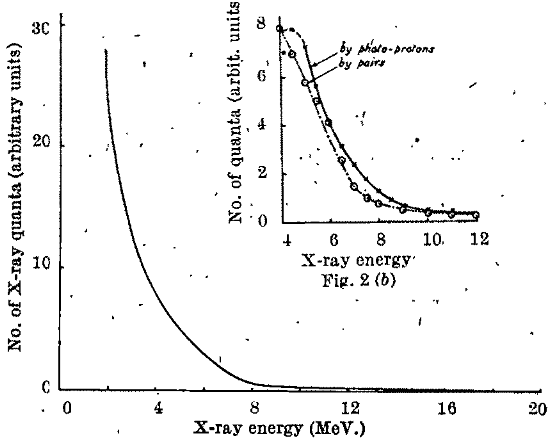

Fig. 2 (*b*)

Fig. 2 (*a*)

Method (*a*) has been used for measuring gamma-ray spectra for many years[3,4], and involves the measurement of the energy (ε) of a large number (N) of pairs (after precautions have been taken to ensure that they are produced by primary photons from the incident beam only). The plot of $N(\varepsilon)d\varepsilon$ against ε, corrected for variations in pair-production cross-section with energy[5], then gives the spectrum. Since this work was started, a modification of the method has been published by Baldwin and Klaiber[6].

Method (*b*) uses the nuclear reaction :

$$D_1^2 + \gamma \rightarrow H_1^1 + n_0^1$$

discovered by Chadwick and Goldhaber[7], who deduced from it the binding energy of the deuteron. Powell *et al.*[8] have suggested that the reaction could be used to measure gamma-ray energies, and more recently a group in the Cavendish Laboratory has used deuterium-loaded Ilford plates to investigate (at about 6 MeV.) the angular distribution with reference to the incident beam of the photo-protons[9]; and their note should be read for an appreciation of the theoretical importance of the reaction.

Fig. 1(*a*) shows a histogram constructed from 65 electron-positron pairs, and the smooth curve drawn through this gave, when corrected for the cross-section variation, the distribution shown in Fig. 2(*a*). Since the number of pairs measured was small, this may be regarded only as provisional, but there would certainly seem to be a large percentage of radiation of less than 5 MeV. energy, which does not agree with the shape of spectrum which has been assumed in some experiments[1]. It must be emphasized (see the discussion below) that Fig. 2(*a*) is not the spectrum that would be obtained if only the target radiation were measured.

Fig. 1(*b*) shows the histogram of 75 recoil proton tracks detected in an Ilford *C*2 Nuclear Research plate in a special camera designed and built by one of us (R. M. P.), so that the protons emitted at 30°–90° with the incident X-rays could be detected. All these tracks were found between 60° and 90°, and the histogram was corrected as shown to give the total number of tracks from 0° to 90°. This was done by finding the variation of angular distribution of the protons with energy from previous published work[9-11]. The smooth curve of Fig. 1(*b*), when corrected by Bethe's cross-section/energy curve, yielded a distribution in good agreement with that of Fig. 2(*a*) down

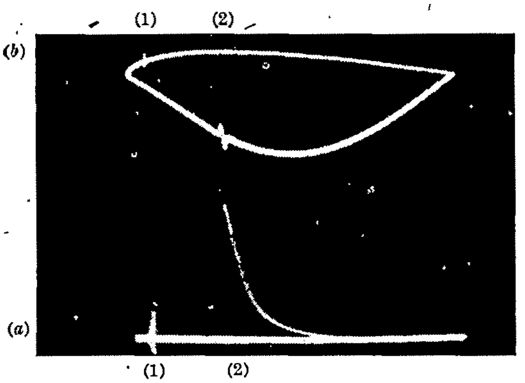

Fig. 3

to an energy of about 5 MeV., below which the proton curve fell off, possibly due to excessive adsorption of the protons in the heavy wax target. The two curves are shown together in Fig. 2(*b*) over the range 4–12 MeV. A point of interest about the two histograms is that neither pairs nor recoil protons were obtained corresponding to an X-ray energy of 7–7·5 MeV., although about five such pairs would be expected.

Although the main purpose of this note is to direct attention to the methods used, and the need for information on betatron and synchrotron spectra, it may be of interest to speculate on the shape of the curves of Fig. 2. The molybdenum target in the betatron (see Kerst[12], Fig. 2) is thin compared with the range of 20-MeV. electrons, and it appears that during the application of the expander pulse the electrons may on the average lose a little ($\sim$ 1 per cent) of their energy at the edge of the target and then oscillate about a new equilibrium orbit, arriving back at the target after several (in our case two) revolutions, then repeating the process. The amplitude of these oscillations therefore increases as the mean orbit radius decreases until the electrons bombard the inner wall of the vacuum chamber, which acts as a thick glass target from which much soft radiation may be expected. However, it should be possible for the 20-MeV. electrons to lose perhaps 10–20 per cent of their energy at the target. It is to be expected that if good collimation were used, so that only radiation arising at the target were observed, then the resulting spectrum would be of the normal *Bremsstrahlung* (thin-target) type. The present experiments are not sufficient to allow the intensities of target and wall radiation to be compared, but are described partly to direct attention to the latter.

Lasich and Riddiford[2] also found much soft radiation but suggested different explanations with which we are inclined to disagree. It is to be expected that soft radiation (probably with much less energy than, say, 2 MeV., cf. Fig. 1*b*) may arise from electrons scattered in the residual gas in the acceleration chamber soon after injection. Fig. 3*a* shows (1) a pick-up pulse due to the injector (see also Fig. 3*b*, 1) and (2) pulses, from a Geiger counter placed in the beam, which all coincide with each other (there were approximately 300 pulses in the time of exposure) at the instant of beam expansion which is shown by the pulse of Fig. 3*b*, 2, thus indicating that scattered radiation arising in the early part of the accelerating period was of negligible intensity.

The above considerations may be proved or disproved by further experiments which it is intended will be carried out. We also hope to publish a more detailed account of the work elsewhere.

We are greatly indebted to Mr. B. Touschek (University of Glasgow) and Mr. F. K. Goward (Telecommunications Research Establishment) for instructive discussions on the work.

EFFECT OF ION-EXCHANGE TREATMENT ON THE STABILITY OF APPLE JUICE

By Dr. S. W. CHALLINOR, MARGARET E. KIESER and Dr. A. POLLARD

Department of Agriculture and Horticulture,
University of Bristol, and Research Station,
Long Ashton, Bristol

ION-EXCHANGE adsorbents have come into increasing use for the de-acidification of fruit juices and extracts[1-3]. In spite of the wide application of such methods in these and related fields, as summarized by Riches[4] and by Davies[5], the effect of such treatments on the 'stability' of juices has, to the best of our knowledge, received little or no attention.

In the course of experiments on the de-acidification of apple juice, a very considerable reduction in the concentration of certain cations and anions took place, as observed by other workers. It occurred to us that such treated juices would be less able to support the growth of micro-organisms and therefore less liable to undergo fermentation. If this were so, it would be of considerable practical importance. In this connexion, Dr. A. K. Zweede of Wageningen had mentioned to us that there was evidence that sugar-beet extracts after treatment with adsorbents showed an increased stability. In our own preliminary experiments, it was found that apple juices subjected to ion-exchange treatments and then freely exposed to air showed much less fermentation than juices not so treated.

In more comprehensive tests, samples of depectinized and pulp-filtered apple juices were passed through laboratory columns of the Permutit ion-exchangers 'De-Acidite *B*' and 'Zeo-Karb *H* 1'. These treatments are summarized in the accompanying table. A marked change in juice composition was produced by the removal of cations in the 'Zeo-Karb' column, accompanied by a corresponding increase in hydrogen-ion concentration. One passage through this adsorbent reduced the total ash in the Blenheim

ION-EXCHANGE TREATMENT AND ITS EFFECT ON JUICE COMPOSITION

Juice	Treatment: 'De-Acidite *D*' or 'Zeo-Karb *Z*'	*p*H	Total ash as % of juice	Constituents as mgm./100 ml. juice					
				Ca	Mg	Cu	Zn	P	N
1. Blenheim Orange	nil	3·62	0·274	14·2	7·0	0·21	0·64	12·4	14·0
2. ,, ,,	*Z*	2·30	0·048	trace	trace	0·03	0·07	12·2	7·0
3. Rival	nil	3·53	0·334	16·9	5·4	0·11	0·81	15·0	13·6
4. ,,	*Z*	2·23	0·049	trace	trace	0·03	0·15	—	—
5. ,,	*Z*, *D*, *Z*	2·33	0·003	,,	,,	0·02	0·07	1·2	1·2

Orange juice (1) to 17·5 per cent and the ash in the Rival juice (3) to 14·7 per cent of the original values. A second passage of the latter juice through the regenerated column, after an intermediate treatment with 'De-Acidite' to reduce acidity, further diminished the ash to 1 per cent of its original value. As these treatments produced a significant change in *p*H, all juices tested microbiologically were first adjusted to their original *p*H by the addition of a solution of sodium hydroxide (analytical grade) in glass-distilled water.

In the initial microbiological tests, pasteurized samples of these juices were separately inoculated as follows: (*a*) with a loopful of a pure wine yeast culture—'Herrliberg'—grown for 24 hours at 25° C. in malt extract; (*b*) with a loopful of a suspension of the same yeast in glass-distilled water, prepared from a 24-hour-old streak culture on malt extract agar; and (*c*) with a loopful of a washed suspension of the mixed microflora obtained by centrifugation from the untreated juice (Rival 3) which had been kept at room temperature for a few days and was actively fermenting. Suspension (*c*) consisted mainly of yeasts, relatively few bacteria being present. Precautions were taken to avoid introducing appreciable quantities of ions either from glassware or from the inocula. Thus, the suspensions were prepared in glass-distilled water and used immediately. The inocula were large—more than 20,000 viable organisms in inocula (*a*) and (*b*), and more than twice that number in inoculum (*c*) for each 7 ml. of juice.

In the earliest experiments—on treated juices of Bramley's Seedling—in which inocula (*a*) and (*b*) only were used, a marked reduction of the growth of yeasts was observed. These encouraging results were followed by experiments on juices which had received more thorough treatment (double passage through 'Zeo-Karb'). Each juice sample was separately inoculated with inocula (*a*), (*b*) and (*c*) and incubated aerobically at 25° C. No growth of the 'Herrliberg' yeast occurred in the treated juice even after two weeks incubation. With the mixed yeast inoculum (*c*) a small deposit formed, sufficient to impart a very slight haze to the juice after vigorous shaking. That only slight multiplication of the mixed yeasts had, in fact, occurred was confirmed by microscopic examination, which showed that the amount of such multiplication was exceedingly small. Furthermore, the yeasts had not the normal healthy appearance of those growing in the untreated juice. These results were confirmed in a subsequent experiment.

The nature of the effects observed in the treated juices presents many interesting problems. We are here interested mainly in those micro-organisms able to cause fermentation, that is, the yeasts and certain bacteria; suppression of the growth of fungi, however, is also of interest. Information on the general nutritional requirements of micro-organisms is not very detailed, but it is known that, in addition to the *main* requirements of carbon, hydrogen, oxygen and nitrogen, other elements or groups are also required. Among these are the following: phosphate, sulphate, carbonate, chloride, sodium, potassium, magnesium, iron, calcium, copper, also possibly manganese, zinc, cobalt and molybdenum. It must be remembered also that the *ratios* of the concentrations of certain ions as well as their absolute quantities may be of significance.

It has not yet been possible to investigate in detail the nutritional deficiencies in our treated juices, but in preliminary analyses the elements given first attention were nitrogen, phosphorus, calcium, magnesium, zinc and copper. The reduction in total nitrogen in the treated Rival juice (5), as shown in the table, was not such as would alone be expected to explain the present findings. The ion-exchange treatments gave most significant reductions in the concentrations of total phosphorus, calcium and magnesium, the two latter being reduced to less than 1 per cent of their original values in this juice. Copper and zinc were also considerably reduced, but to a less marked extent. Spectrographic analysis of the earlier juices, made possible by the courtesy of the International Smelting Corporation, Avonmouth, confirmed the presence of calcium, magnesium, copper and zinc in the treated and untreated juices. Traces of manganese were also present, but molybdenum was not detected.

In a further series of microbiological tests the following salts (analytical grade) were added to the treated juice, either separately or in combination, in amounts comparable with those present originally: ammonium sulphate (nitrogen and sulphate), ammonium phosphate (nitrogen and phosphate), magnesium sulphate and calcium chloride. The juices were inoculated with the microflora of the Rival juice (3) and incubated at 25° C. After a *short* period of incubation (three days), appreciable growth appeared only in the juices containing both added nitrogen and phosphorus, there being no marked difference between that containing added nitrogen and phosphorus only and that receiving nitrogen, phosphorus, magnesium and calcium; growth, however, was very considerably less than in the original untreated juice. After a further three days incubation there was a marked difference between the juice receiving the four nutrients and that receiving nitrogen and phosphorus only; in fact, the amount of growth in the former was then of the same order as in the untreated juice.

The microbiological tests have been carried out aerobically. It should be borne in mind that apple juice is normally stored under conditions of restricted oxygen supply: under such conditions, however, the effects of ion-exchange treatment on juice stability would be expected to be similar or even more marked. Some evidence that this is so has been obtained from an experiment under less aerobic conditions.

We have attempted to apply these findings by storing treated and untreated juices in the laboratory at ordinary temperatures. Although the juices were unpasteurized and no aseptic precautions were observed, the treated juice (Rival 5) showed no obvious fermentation during the period of observation (four weeks); some slight mould growth, however, occurred. Juice which had been de-aerated and bottled under carbon dioxide showed even greater stability. The untreated juice (Rival 3) was rapidly fermenting within three days.

It is thus apparent that ion-exchange treatment of apple juice effects the removal or partial removal of nutrients necessary for the growth of micro-organisms. Juices so treated become very much less liable to microbiological spoilage. Further experiments on this and other aspects of the work are in progress. If it should prove practicable to produce similar changes in juice composition affecting the growth of micro-organisms by ion-exchange treatment on a commercial scale, then the industrial production of apple juice—and possibly of other fruit juices—might be radically changed in respect of processing procedure, storage and the ultimate stability of the finished product. It is obvious also that the results here recorded open up far-reaching possibilities in connexion with the preparation and stability of other types of fruit products, for example, cider and perry.

We wish to thank the Permutit Co., Ltd., for samples of the adsorbents used in this work.

THE ROYAL SANITARY INSTITUTE

THE Annual Congress of the Royal Sanitary Institute was held at Harrogate this year during May 24–28. On May 28, a joint meeting was held with the Food Group of the Society of Chemical Industry to discuss the cleaning and sterilizing of plant in the food industry. After an introduction by Dr. E. B. Hughes, chairman of the Food Group, papers were presented by Dr. J. G. Davis on "The Cleaning and Sterilizing of Dairy and Ice Cream Plant", by Mr. H. J. Bunker on "The Hygiene of Beer Production and Consumption", and by Mr. D. H. F. Clayson and Mr. C. W. Chater on "The Cleaning and Sterilization of Plant and Utensils in the Food Industry".

Dr. Davis defined cleaning as the removal of all residues and particularly those which serve as a food for bacteria. Sterilization is only a finishing process, cleaning being the more important operation. Unless all food residues are removed, the few remaining bacteria can proliferate rapidly in the presence of food, moisture and warmth. A reasonable standard for commercial sterility or 'sanitization' is one colony per ml. capacity or per square centimetre of surface.

Although different methods can be used successfully, all methods conform to certain fundamental principles, which were enumerated as follows:

(1) Cleaning and sterilizing must always be regarded as distinct and different operations.

(2) The first treatment should always be a cool or tepid water rinse. Cold water hardens the fat, and hot water denatures the water-soluble proteins which with calcium salts form a strongly adhering film. Hard water should be softened.

(3) The second treatment should be with a suitable detergent solution applied as hot as possible. This emulsifies the fat and proteins, partially saponifying or hydrolysing them; and finally washes away the broken-down and loosened milk constituents. The emulsifying power of the detergent solution is related to the surface tension and to its ability to penetrate between dried-on milk film and the metal surface.

(4) Should any milkstone be visible after the detergent treatment, this must be removed by a weak acid solution, as otherwise the sterilizing will not be efficient. Milkstone does not normally form unless milk is heated, and so is found chiefly in the hot sections of pasteurizing plant. Frequency of acid treatment depends on the type and individuality of the plant, the milk supply, the time of running, the temperature used and other variable factors.

(5) 'Scale', or 'fur', resulting from the use of hard water is inimical to sterilizing, and can be particularly troublesome in bottle-washing machines. As with milkstone, the dilute acid treatment is necessary for its removal. In order to avoid corrosion, inhibitor preparations should be incorporated in the acid solution. These generally consist of organic nitrogen compounds of the quinoline type.

(6) Special precautions must be observed with certain metals, particularly aluminium and tin. Detergents for use with aluminium and tin should contain at least 25 per cent silicate, and preferably no caustic soda at all. The incorporation of about 10 per cent of sodium sulphite has been recommended to prevent corrosion of tinned plate, but this is only rarely used in Great Britain. All metals, including stainless steel ('crevice attack'), can suffer corrosion with chlorine, especially if used with soft water which has a low *p*H.

(7) After cleaning, equipment should be left either dry or in contact with the sterilizing solution. The better method is to keep thoroughly clean plant in a dry condition, as bacteria cannot grow without moisture.

In discussing dairy equipment, it was emphasized that on the farm the best results can be obtained with very simple and home-made equipment. On farms where the buildings, etc., are in very bad condition it has been shown that it is possible to produce milk of good-keeping quality provided there is a good supply of clean, cold water, and the utensils are thoroughly washed.

On the other hand, in farms with excellent buildings and the very latest and often expensive equipment, poor-keeping quality in milk is sometimes found where there is a lack of clean, cold water, and where apparently trivial but, in reality, serious mistakes are made in the cleaning and sterilizing of the equipment.

Churns are generally treated by pre-rinse, hot rinse or hot detergent, hot rinse, steam, and sometimes hot air at 240° F. The author expressed his preference for a final steaming which left the churn very hot at the mouth rather than for a final treatment by hot air. For containers which have to be emptied and cleaned quickly, a preference was expressed for a chlorine wash rather than for steam for sterilizing.

Pipelines should be taken down every day; but some dairies get satisfactory results by only stripping every second or third day. On the Continent, plant is treated by dilute nitric acid, detergent and final rinse, and only rarely taken down; but this method has not been generally adopted in Great Britain. Pasteurizing plant should be dismantled at least once every day and thoroughly cleaned and sterilized. The modern high-temperature-short-time pasteurizing plant is not susceptible to thermophilic growth as is the 'holder' plant.

Only a very small proportion of bottles are now scalded with steam or hot water. Most big dairies employ bottle-washing machines which use hot detergent at 140° F., which both cleans and sterilizes bottles. It is important, however, to maintain rinse solutions in a satisfactory bacteriological condition.

In dealing with some special aspects of problems in the dairy industry, the author emphasized the significance of the individuality of utensils, and the effect of atmospheric temperature on the bacteriological condition of utensils and plant, the importance of the interval between sterilizing and use, and further pointed out that the larger the container the smaller is the relative contamination by a given number of bacteria per unit of surface.

Hypochlorite solution used for sterilizing is sometimes used at an unnecessarily high strength, about 150 p.p.m. at a minimum temperature of 120° F. for a minimum time of 2½ minutes being recommended. Too strong a chlorine solution might lead to serious corrosion, especially when the water is soft.

Mr. H. J. Bunker, in dealing with the hygiene of beer production and consumption, briefly described stages in the making of beer. The malting of the barley is followed by the grinding of malt and mashing of the ground malt or grist. The wort is next boiled for some time and the hops added. The boiled wort is then pitched or inoculated with yeast, and fermentation allowed to proceed. The beer is finally run to cellars, where it is emptied into casks or held in a container from which, after a few days, it is bottled, with or without filtration, according to the type of beer. After bottling it may be pasteurized, but in Great Britain the greater part of the bottled beer is not heat-treated.

On account of its high acidity, beer is one of the safest of foods from the bacteriological point of view. The *p*H of beer is usually about 4 and this probably explains why pathogenic bacteria are always absent. In addition, hops and alcohol are factors inhibitory to bacteria. The prolonged boiling of the wort gives complete sterility at one stage, and the author was of the opinion that the maintenance of clean mains was the most important item of hygiene in the brewery. The cleaning of these mains must be a regular operation, for which caustic soda solution is commonly used.

Beer is now generally cooled in a built-in type of cooler which has the advantage that delivery is achieved in a closed system without intermediate exposure to infection.

A point of some importance in the cleaning of brewery plant, which might consist of copper, wood, slate, aluminium, stainless steel or wax-lined materials, is the fact that in course of time a deposit known as 'beerstone' forms on the side of the fermenting vessel. The modern brewer prefers to remove this beerstone and thus eliminate what would otherwise become a dangerous lurking place for micro-organisms.

Bottles and bottle-filling machines require particular attention. In bottle-washing, caustic soda is the chief constituent of the detergent, and the general standard of cleanliness in these machines is now very high.

Preservatives are not added to bottled beers, the old idea that the brewer adds chemicals to beer being entirely erroneous. The only preservative which is permitted in brewing is sulphur dioxide.

One of the chief sources of contamination in breweries is old cellar floors which, when they become cracked, are difficult to clean. Such floors can be treated with chloride of lime or 'Antiformin' (sodium hydrochlorite and sodium hydroxide). Phenolic antiseptic should not be used, for obvious reasons.

Mr. Bunker next dealt with the very important aspect of hygiene in beer houses and named three methods for dealing with the problem of glasses: (*a*) the automatic glass-washing machine; (*b*) the self-emptying sink; (*c*) the addition of some suitable detergent or antiseptic to the rinse water. He expressed a preference for the third method and described recent work on the use of quaternary ammonium compounds for this purpose.

Dealing finally with the question of drying cloths, Mr. Bunker said that most bar-tenders prefer to dry and polish glasses after rinsing. If the cloths are allowed to get dirty they may well put back on the glasses more organisms than were there before drying. It is essential that any cloths used should be in a good bacteriological condition.

Mr. Clayson and Mr. Chater, in dealing with the present-day communal feeding in restaurants and canteens, stated that the effects of inadequate hygiene in the kitchen may be serious. Although machine-washing is growing in restaurant kitchens this method is not foolproof, and in the authors' experience there is not much difference between the results of hand-washing and machine-washing.

They pointed out that dirt is not defined from the legal point of view and that it is necessary, in order to comply with the Food and Drugs Act (1938), to define processes that can be relied upon to destroy or remove pathogenic organisms if they should be present. This definition would have to be in chemical or physical terms in relation to detergent concentrations, temperatures, times, etc. With highly glazed or polished articles the appearance is a very good guide to their hygienic condition. This question is important because the removal of soiling deposits from food utensils is an important stage in securing a satisfactory hygienic condition.

Instead of stating that a certain organism is destroyed in a certain time at a certain temperature, it is preferable to refer to destruction-rates, for example, the decimal reduction time, which is the time required to reduce the count to one-tenth of what it was originally. The decimal reduction time of most intestinal organisms is of the order of one minute at 140–145° F. At 160° F. or over the decimal reduction time values of staphylococci and streptococci are a matter of seconds only.

Thermoduric organisms are of little sanitary significance. 'Sanitization' may therefore be defined as a treatment which eliminates pathogenic and food-poisoning micro-organisms but which may not destroy thermoduric organisms.

The extent of dispersion of soiling material depends upon the volume of wash water, the mechanical force applied, the volume of rinsing water and the frequency with which the washing and rinsing waters are changed. If the sterilization process consists of immersion in hot water or disinfectant solution, a satisfactory cleaning has the additional advantage that any remaining bacteria are easily dislodged from the surface. With satisfactory washing it is possible to achieve a high degree of sterility by immersing the articles for a much shorter time in the rinse water than would be required if all the bacteria remained attached to the surface.

The United States Public Health Service Code requires: (1) a cleaning process with a detergent solution at 110–120° F.; (2) sterilization (with a choice of four methods); and (3) drying with clean cloths, or preferably by evaporation. The standards required in the United States give, apparently, a very wide margin of safety if the conditions for high-temperature-short-time pasteurization, that is, 162° F. for not less than fifteen seconds, can be taken as a guide for the destruction of pathogenic organisms. Evaporation after hot-water rinsing is preferable to drying by a cloth.

For utensils with thick or dried-on deposits, machines which allow a long period of contact with detergent solution are necessary. An important point in the design of such machines is the avoidance of excessive carry-over of the detergent solutions to the rinsing compartments.

A plant used for the preparation, service and storage of food needs the same if not more attention from the hygienic point of view than the multi-service utensils.

To obtain a bactericidal effect with steam it is essential to keep the steam in an enclosed space with a comparatively small vent and to continue steaming for at least three minutes after steam issues from the vent at over 205° F.

The authors suggested that it would be sometimes advisable to employ two different types of sterilizing treatment, for example, steam and hypochlorite solution, with the object of destroying organisms which might escape one of these treatments, but no experimental evidence was quoted in support of this view. Hypochlorite treatment must, of course, be followed by further rinsing with cold water.

WIGAN MINING COLLEGE

FOUNDED on October 27, 1857, Wigan and District Mining and Technical College has just celebrated its ninetieth anniversary. In its first session the average attendance was 15; now it has some 2,800 students. The intervening ninety years show a continuous record of expansion and progress in spite of many difficulties. Like most higher institutions of learning in Britain to-day, the College is overcrowded and badly in need of extended accommodation and additional facilities, particularly for postgraduate and research work. Founded primarily to develop mining education, and still maintaining a leading position in that field, it has never confined itself to mining alone. Its range of work covers also engineering, chemistry, physics, geology, biology, mathematics, building, commerce, economics, art, and other subjects.

A special feature of the work of the College is the provision of complete full-time courses for the degrees of the University of London in mining, engineering, general science, chemistry, physics, geology, mathematics and economics. The College is inspected and recognized by the University in connexion with the mining and engineering degree courses. It is also recognized by the Board for Mining Examinations, the Board of Trade, the Institution of Civil Engineers, the Institution of Mining Engineers, the Royal Institute of Chemistry, the Institute of Physics, etc. It is the headquarters of the Manchester Geological and Mining Society and provides accommodation for meetings of many other scientific, technical and professional bodies. A notable feature of its work is the development of its library and refectory services and of student activities. It has in Christopher Park one of the finest athletic grounds in the north of England.

A meeting to celebrate the ninetieth anniversary was held in the College hall on June 7. This was attended by a very representative gathering, including educationists, scientific workers, industrialists, and government and local officials, as well as governors, staff and students. The chairman of the Governing Body, Colonel J. S. A. Walker, presided, and the principal, Dr. J. F. S. Ross, gave a brief survey of the history and work of the College, directing attention to the devoted service it had received from its founders and their successors, its long-standing regional character and independence—it receives very substantial grants from the Lancashire and Wigan Education Authorities but possesses its own freehold land and buildings and has its own autonomous governing body—and to the development within it of a truly educational and collegiate spirit. The chairman of the General Purposes Committee, County Councillor A. Guest, who has been a governor of the College for the last third of a century, also referred to aspects of its history and directed attention to its high reputation at home and abroad. Notwithstanding the invaluable help of local authorities, the College needs greater financial resources, and he thinks it should receive these on lines comparable with those on which university colleges are helped by the University Grants Committee.

Sir Charles Ellis, scientific member of the National Coal Board, gave an address on "The Place of Science in a Technical Training". After commenting on the high reputation of the College in science and industry —he had heard from everyone in a position to judge that Wigan-trained people had a sound knowledge of and lively interest in the fundamental sciences and a genuine appreciation of the means of applying them to technological problems—Sir Charles referred to the distinction between industrial scientists and research scientists, and denied the validity of any difference of status between them. He mentioned the manifold duties of scientific men in connexion with the National Coal Board: while the majority of them are in the colliery chemical services and carry out their scientific duties in daily contact with industry, there are other groups which have more national standing. He mentioned the special group dealing with the survey of coal seams in Britain, and said that we have an accurate knowledge of the quality of our coal seams for many years ahead before they are mined. He also referred to the research group engaged on fundamental studies of coal substance. These are doing pioneer work. He went on to develop a closely reasoned argument as to the intrinsic value of scientific education, not only in relation to industry but also in inculcating a genuinely philosophical attitude to life. The address is to be published by the College in pamphlet form.

An illustrated booklet on the College has been issued in connexion with the ninetieth anniversary; copies can be obtained from the College office, price 1*s.* 6*d.* each.

FORTHCOMING EVENTS

Wednesday, June 30

Institute of Welding (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 2.30 p.m.—Annual General Meeting.

Friday, July 2

Physical Society (in the Physics Department, Imperial College of Science, Imperial Institute Road, London, S.W.7), at 5 p.m.—Mr. J. Hamilton: "The Theory of Radiation Damping"; Mr. R. M. Sillitto: "An Extension of Kapitza's Theory of δ-Radiation".

Geologists' Association (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Sir Arthur Russell, Bart.: "Early British Mineral Collectors and Mineral Collecting".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Anatomy, preferably with some experience in Histology—The Secretary, The University, Aberdeen (July 3).

Lecturer in Education—The Secretary, The University, Edmund Street, Birmingham 3 (July 3).

Lecturer in Physics up to B.Sc. standard—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (July 3).

Assistant Agricultural Economists (2), and a Lecturer in Agricultural Economics—The Registrar, King's College, Newcastle-upon-Tyne (July 3).

Lecturer in Statistics in the Department of Economics and Social Science—The Registrar, University College of South Wales, Cardiff (July 5).

Lecturer or Assistant Lecturer in the Department of Botany, a Demonstrator in the Department of Chemistry, and a Second Demonstrator in the Department of Zoology—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (July 5).

Lecturer in Physiology, an Assistant Lecturer in Geography, and Tutorial Studentships in Botany, History, Mathematics, Physics and Zoology—The Registrar, King's College, Strand, London, W.C.2 (July 5).

St. Mungo (Notman) Chair of Pathology—The Secretary of University Court, The University, Glasgow (July 7).

Lecturer in Inorganic and Physical Chemistry—The Secretary, The University, Edinburgh (July 15).

Research Officer in the Division of Plant Industry, Canberra—The Secretary, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 1740 (July 17).

Principal Research Officer or Senior Principal Officer (Ref. No. 1749), and Research Officers (3, Ref. No. 1750), in the Division of Economic Entomology, Canberra—The Secretary, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (July 17).

Research Officer in the South African National Physical Laboratory, Pretoria—The South African Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2 (July 19).

Chair of Chemistry—The Secretary, The University, Aberdeen (July 31).

Librarian in the Department of the Scientific Adviser to the Army Council at the War Office, a Librarian and Assistant Librarians (2) at the Military College of Science, Shrivenham, Swindon—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2183 (July 31).

Principal Scientific Officer (responsible for advising commercial undertakings and hospitals as to the application of radioactive isotopes, and for the scientific planning for production of isotopes in close association with chemical and nuclear physics research groups), a Principal Scientific Officer (to lead a Physics Production Group for radioactive isotopes and responsible for the irradiation of materials, their standardization and packing), a Senior Experimental Officer (responsible for implementing processes evolved by a research group for production of radioactive isotopes and to head a group of chemists engaged on routine isotope production), and Experimental Officers (2, responsible for routine testing, packing and dispatch of radioactive material), at the Atomic Energy Research Establishment of the Ministry of Supply—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2185 (July 31).

Professor of Organic Chemistry, and a Professor of Theoretical Physics—The Registrar, Indian Association for the Advancement of Science, 210 Bowbazar Street, Calcutta 12, India (August 1).

Scientific Assistant for the collation, abstracting and reviewing of biological literature—The Director, Commonwealth Bureau of Plant Breeding and Genetics, School of Agriculture, Cambridge (August 1).

Heads of the Departments of (*a*) Architecture and Town and Regional Planning, (*b*) Civil and Sanitary Engineering, (*c*) Electrical Engineering, (*d*) Mechanical Engineering, (*e*) Chemical Engineering, (*f*) Geology and Geophysics, (*g*) Naval Architecture and Marine Engineering, and (*h*) Textile Technology, in the proposed Eastern Higher Technical Institution near Calcutta—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2, quoting No. 396W (August 20).

Director of the proposed Eastern Higher Technical Institution near Calcutta—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2, quoting No. 403W (August 20).

Entomologist to carry out a survey of the tsetse areas of the Sudan and undertake research work—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Entomologist'.

Laboratory Technician to take charge of the Physics workshop—The House Governor, Queen Elizabeth Hospital, Birmingham 15.

Laboratory Assistant (male) in the Department of Chemistry—The Steward, Department of Chemistry, The University, Manchester.

Laboratory Assistant (Grade B 1) for general laboratory and histological routine—The Professor, Department of Human Anatomy, The University, Oxford.

Student Technician for Bacteriological Department—The Secretary, University College Hospital, Gower Street, London, W.C.1.

Meteorologists in the Meteorological Service of the Sudan Government—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Meteorologists'.

Senior Crop Recorder—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Professor of Physics and Electrical Engineering at the Royal Naval College, Greenwich—The Director (P.A.), Education Department, Admiralty, London, S.W.1.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Ministry of Agriculture and Fisheries. Bulletin No. 139: Report on Fungus, Bacterial and other Diseases of Crops in England and Wales for the Years 1943–1946. By W. C. Moore. Pp. vi+90+12 plates. (London: H.M. Stationery Office, 1948.) 2*s*. 6*d*. net. [115

Scottish Zoo and Wild Life. (The Magazine of the Zoological Society of Scotland.) Quarterly. Vol. 1, Part 1, April. Pp. 48+9 plates. (Edinburgh: Oliver and Boyd, Ltd., 1948.) 3*s*. net; annual subscription, 12*s*. [115

National Forest Park Guides. Snowdonia. (Issued by H.M. Forestry Commission.) Pp. 72. (London: H.M. Stationery Office, 1948.) 2s. 6*d*. net. [115

Forestry Commission. Empire Forests and the War: Statistics prepared for the Fifth British Empire Forestry Conference, Great Britain, June 1947. Pp. ii+18. (London: H.M. Stationery Office, 1948.) 1*s*. net. [115

British Intelligence Objectives Sub-Committee. Overall Report No. 2: Shipbuilding and Marine Engineering in Germany during the Period 1939–1945. Prepared by F. J. C. Jacob. Pp. 20. (London: H.M. Stationery Office, 1948.) 6*d*. net. [125

Commonwealth Economic Committee. Industrial Fibres: a Summary of Figures of Production, Trade and Consumption relating to Cotton, Wool, Silk, Flax, Jute, Hemp, Mohair, Coir and Rayon. Compiled in the Intelligence Branch of the Commonwealth Economic Committee. Pp. 137. (London: H.M. Stationery Office, 1948.) 5*s*. net. [12

Other Countries

Sugar Research Foundation, Inc. Technological Report Series No. 4: Use of Molasses in Grass Silage Preparation. By Prof. Carl B. Bender. Pp. v+22. (New York: Sugar Research Foundation, Inc., 1948.) Free. [115

University of Illinois Engineering Experiment Station. Bulletin Series No. 369: Studies of Highway Skew Slab-Bridges with Curbs, Part 1, Results of Analyses. By Vernon P. Jensen and John W. Allen. Pp. 62. 75 cents. Bulletin Series No. 370: The Illinois Smokeless Furnace. By Prof. Julian R. Fellows, Prof. Alonzo P. Kratz and Prof. Seichi Konzo. Pp. 78. 75 cents. Bulletin Series No. 371: Rate of Propagation of Fatigue Cracks in 12-inch by ¾-inch Steel Plates with Severe Geometrical Stress-Raisers. By Prof. Wilbur M. Wilson and James L. Burke. Pp. 14. 35 cents. Bulletin Series No. 372: The Effect of Non-Uniform Distribution of Stress on the Yield Strength of Steel. By Dimitry Morkovin and Omar Sidebottom. Pp. 72. 50 cents. (Urbana, Ill.: University of Illinois Engineering Experiment Station, 1947.) [125

University of Illinois Engineering Experiment Station. Circular Series No. 52: The Railroad Dynamometer Car of the University of Illinois and the Illinois Central Railroad. By Assoc. Prof. John K. Tuthill. Pp. 34. (Urbana, Ill.: University of Illinois Engineering Experiment Station, 1947.) 20 cents. [125

Revista del Museo de Historia Natural de Mendoza. Vol. 1, No. 1, Diciembre 31, 1947. Pp. 64. (Mendoza: Museo de Historia Natural, 1947.) [185

University of Illinois Engineering Experiment Station. Bulletin Series No. 374: The Free Surface Around, and Interference between, Gravity Walls. By Prof. Harold E. Babbitt and David H. Caldwell. Pp. 58. 50 cents. Bulletin Series No. 375: Studies of Slab and Beam Highway Bridges, Part 2, Tests of Simple-Span Skew I-Beam Bridges. By Prof. Newark M. Newmark, Asst. Prof. Chester P. Siess and Warren M. Peckham. Pp. 60. 50 cents. Bulletin Series No. 376: Highspeed Freight Train Resistance, its Relation to Average Car Weight. By Assoc. Prof. John K. Tuthill. Pp. 77. 50 cents. Bulletin Series No. 377: Flexural Fatigue Strength of Steel Beams. By Prof. Wilbur M. Wilson. Pp. 32. 20 cents. (Urbana, Ill.: University of Illinois Engineering Experiment Station, 1948.) [185

Catalogues

Botany, Birds, Sea-Life, Geology, Butterflies, Moths and Scientific Voyages round the World. (Catalogue No. 689.) Pp. 62. (London: Francis Edwards, Ltd., 1948.)

Medieval Literature: Literature and History, Philosophy and Theology, Science and Medicine. (Catalogue 9.) Pp. 88. (New York: Herbert Reichner, 34 East 62nd Street, 1948.)

Johnson Matthey Products and Services. (Publication No. 1000.) Pp. ii+30. (London: Johnson, Matthey and Co., Ltd., 1948.)

Gold—Engineering Properties and Uses. (Publication No. 2020.) Pp. 12. (London: Johnson, Matthey and Co., Ltd., 1948.)

Towers Laboratory News. No. 5 (Special B.I.F. edition). Pp. 117–164. (Widnes: J. W. Towers and Co., Ltd., 1948.)

Murfume Azobenzene Smokes for Horticultural Use. Pp. 4. (Wheathampstead: Murphy Chemical Co., Ltd., 1948.)

Plant Protection Overseas Review. Vol. 1, No. 1, May 1948. Pp. 36. (London: Plant Protection, Ltd., 1948.)
